The body of the tap or valve which is adapted to be screwed or otherwise connected with the supply pipe or passage and usually also to a delivery pipe is formed with a water or fluid way through it. A conical hole is formed in the body from one side and into it a corresponding plug fits which when in its place closes the water or fluid way through the body. On the side of the body, and over the conical recess for the plug, a chamber is formed, and when the plug is drawn back to open the water or fluid way it is received into this chamber and leaves the passage way clear of all obstructions with an undiminished area for the direct inlet and outlet of the volume of steam, water, or other fluids which may be conveyed to the passage; the plug is raised and lowered by a screw, the stem of which passes through the cover of the chamber and receives a handle or hand wheel on the exterior.—Patent completed.

282 G. HAWKESLEY, Caledonian-road. *Pumps.* Dated January 29, 1869.

The inventor casts the barrel with a foot at its lower end by which it is fixed, and at its upper end a head and spout suitable to receive and deliver the water from the barrel and to support the fulcrum of the lever handle. Below the portion of the barrel to which the pump bucket is fitted is a cavity of larger diameter closed at the bottom with the exception of the suction passage which passes through it, and beneath which is a socket receiving the suction pipe. Into the cavity at the lower end of the barrel is a side opening closed air-tight by a cover. The cover has lugs upon it on the inner side, and a piece of sheet india-rubber or leather, which forms both the hinge and the packing of the valve over the suction passage, is held by these lugs, which are simply passed through holes formed for them in the india-rubber. The metal valve is connected with the india-rubber by means of a central boss on the valve, over which the india-rubber is sprung, a corresponding hole being formed in the india-rubber and a groove being cut around the bottom of the boss into which the india-rubber nips.—Patent completed.

283 G. PRICE, Birmingham. *Window fastenings.* Dated January 29, 1869.

Upon the one part of the fastening is formed the circular catch plate in the ordinary way as a fixture thereupon, and a movable catch is provided secured to the circular catch plate as a hinge by a vertical rivet pin passing through the parts. The movable catch has a spring action by means of the spring secured to the side of the circular catch plate, the spring always bearing and pressing inwards. The movable catch is curved or rounded at its free end and is suitably cut or recessed to engage with and fit around a raised stud piece. The raised stud piece is formed upon the lever arm or catch bar upon the other part of the fastening, which is made in the ordinary manner with the exception of the knob or handle end, upon which a movable friction or cam plate is attached, by means of the stud piece which acts as a centre or pin for the friction or cam plate, a suitable handle or thumb piece being formed to project from and as part of the friction or cam plate.—Patent completed.

234 J. H. JOHNSON, Lincoln's-inn-fields. *Steel piles.* (A communication.) Dated January 29, 1869.

This consists in the forming of iron or steel into piles, faggots, or billets preparatory to rolling by pressing the metal into forms of the required shape; also in forming iron or steel into hollow piles or billets preparatory to rolling into hollow articles such as pipes or columns. Various combinations or arrangements of machinery may be employed in manufacturing pressed and moulded piles or faggots, as above described, but that which the inventor has found to give the best results consists of a hydraulic or other powerful press, the ram of which carries a plunger which accurately fits inside a strong metal case or mould of any desired size and transverse section, the sides of such mould being capable of opening on hinges in order to release the compressed and finished pile; the blooms having been placed in the mould and the sides closed down and secured, the plunger is caused to enter through one end of the mould which is left open for that purpose, and to forcibly compress by the action of the hydraulic press the metal contained inside the mould, thereby not only expelling the impurities which may be in the bloom and which escape through the joints in the mould, but causing the metal to be thoroughly consolidated and to take the exact form of the mould.—Patent completed.

285 A. M. CLARKE, Chancery-lane. *Hulling grain.* (A communication.) Dated January 29, 1869.

This consists in removing the husks from the grain by means of friction. The ears pass between two rollers grooved either in straight or curved lines.—Patent completed.

287 F. JAY, South Lambeth-road. *Paint.* Dated January 29, 1869.

The inventor proposes to use any or all the ingredients now used in the manufacture of paints, but the peculiarity of his invention consists in utilizing or using together with such ingredients the common resin of commerce in combination with oxide of zinc. This combination has not heretofore been employed in the manufacture of paint applicable to the various purposes for which ordinary paint is used.—Patent completed.

289 T. WHIMSTER, Perth. *Forcing gases.* Dated January 30, 1869.

The apparatus is rotary and comprises a drum fixed on and turned by means of a horizontal shaft being placed in a casing partly filled with water or other suitable liquid. The space above the water is divided into three compartments by two hanging partitions, which dip down below the surface of the water, and the drum is in the middle compartment between the two partitions, whilst it is with the same middle compartment that the pipe for admitting the gas communicates. The drum may be varied in form, but it is preferred to construct it with two plain discs formed with eyes at the centres and connected by spirally bent partitions.—Patent completed.

292 T. PIMBLEY, Bayham-street, Camden Town. *Communicating in trains.* Dated January 30, 1869.

The compartment of each carriage is to contain a handle which when pulled will communicate by wire with boxes fitted on to under carriage. These boxes contain alarm signals, one of which will be dropped from each box on to the metals (or rails) in front of wheels which in passing over will cause an explosive alarm which can be heard by every passenger in the train, as well as by the guard and driver (immediately on the handle being pulled), and as only one signal will drop out of each box the alarm may be repeated if necessary. Patent abandoned.

293 S. TAYLOR, Sheffield, and G. W. DYSON, Tinsley. *Spade and shovel moulds.* Dated January 30, 1869.

The inventors take a bar of iron or steel, or of steel and iron combined, and forge, cut, or stamp it to the shape of an ordinary mould, leaving the strap end solid. They then form the straps by splitting this solid end with a circular saw or with cutters, and having cut down the goffer and weld or otherwise treated the strap ends, they proceed to roll or plate out the moulds in the ordinary manner.—Patent abandoned.

294 H. N. NISSEN, Mark-lane. *Printing bankers' cheques.* Dated January 30, 1869.

The inventor employs paper either white or coloured with a highly-glazed surface, on which he prints in the ordinary manner, but with specially prepared ink or colour. In this preparation, having ground his colour with glycerine, starch, flake white, or a saccharine matter, preferably pure syrup without colour, or with a mixture of any of the above ingredients, and in such proportions as shall not detract from the brilliancy of the colour employed, by which he is enabled to produce a perfectly soluble surface printing colour.—Patent abandoned.

295 K. C. WATSON, Glasgow. *Boats.* Dated January 30, 1869.

One or more lines of chains, ropes, straps, or bands are attached to and stretched from the bow to the stern on each side of the boat. The first line is situated a distance below the gunwale of the boat equal to the depth which it would sink beneath the surface of the water when the boat is upset, so that persons who have been thrown out of the boat and are floating in the water may easily grasp a chain or band. The other lines are situated a short distance apart from each other nearer to the keel of the boat, so that by means of these persons in the water may lift themselves on to the bottom of the boat, and in so doing the bottom of the boat will be upturned and "righted" by the unequally distributed weight on each side of its longitudinal axis.—Patent completed.

296 E. T. HUGHES, Chancery-lane. *File planing machine.* (A communication). Dated January 30, 1869.

This file-planing machine is principally intended for planing arm and smooth files worn out by long use in lieu of the present expensive whetting process they were hitherto subjected to previous to their being cut. A file of 4lb. weight requires upwards of 20 minutes' whetting, whilst its planing is completed in one minute.—Patent abandoned.

297 E. T. HUGHES, Chancery-lane. *File-cutting machine.* (A communication.) Dated January 30, 1869.

The chief driving axle is set in motion by straps from any suitable motor, and drives by two tappets the tilt hammer, which is fixed to its axle. This hammer actuates the chisel, which strikes its blows upon the file. The said file rests on a lead cushion on an anvil, which is moved by cog and bevel wheel gear by a screwed axle. To withdraw the anvil the driving strap is pushed upon a disc, whereby the motion is transferred to other axles by a toothed wheel and toothed shaft which are fixed to the said anvil. The vice jaws for holding the file must be previously separated from the screw mandrel, which is brought about by raising a weight and a chase in connection therewith.—Patent abandoned.

299 J. TOLSON, Dalton. *Cleaning cards.* Dated January 30, 1869.

This consists in the employment or use of self-cleaning revolving combs, or a series of combs of suitable length according to the length of the card cylinders or rollers to be cleaned, working in eccentric grooves within a rotary cylinder, so as to move in and out through slits in the rim thereof as the cylinder rotates, and so that at one part or position of the cylinder in its rotation the comb teeth will protrude through the slits, and at the opposite part the said teeth will be withdrawn within the surface of the cylinder.—Patent completed.

300 G. H. ADAM, Birmingham. *Engine reflector.* Dated January 30, 1869.

This consists in attaching to the locomotive engine a plane mirror on one side or on each side of the locomotive, the mirror or mirrors being fixed at or about the height of an ordinary man, and so inclined that in looking into the mirror or mirrors the enginedriver may be able to see by reflection from the said mirror or mirrors the several carriages of the railway train.—Patent abandoned.

301 T. H. KILNER, Lepton. *Feed apparatus.* Dated January 30, 1869.

The inventor uses an endless travelling feed sheet, which passes round a supporting roller (having its bearings in a travelling carriage on the frame at either side of the apparatus) over pulleys at the end of the frame and around a travelling roller working in "races" at the bottom part of the frame. To the travelling carriage he connects a chain at either side, which is caused to pass over a toothed disc on a revolving shaft, over a second similar one near the bottom of the frame, and thence to the travelling roller (working in the race at the bottom of the framework), to the axis of which it is connected.—Patent abandoned.

302 A. L. ANDREWS, James-street, Old-street. *Horse collars.* Dated January 30, 1868.

It is proposed to make the pad of the collar of india-rubber or other airproof or suitable material covered on the one side with soft fabric, such as moleskin cloth, and on the other with linen, drill, or other like fabric for the purpose of strengthening the india-rubber, to which the covering and lining are cemented with india-rubber solution or otherwise secured. This pad is to be either inflated or filled with air or fluid, or with any soft and elastic material, such, for example, as the material known as "moo main," horse hair, wool, and stuffing fibre.—Patent completed.

303 J. T. BINTLEY, Kendal. *Billiard and bagatelle tables.* Dated January 30, 1869.

The inventor fixes at the sides of such tables a trough fixed and inclined in such manner that the balls dropping into any of the pockets will fall into such trough and travel along the same into the aforesaid tray or receptacle. —Patent abandoned.

APPLICATIONS FOR LETTERS PATENT.

Dated August 17, 1869.

2450 T. J. Leigh, Mostyn-road, Brixton, Surrey. Improvements in furnaces.

2451 R. H. Charsley, Beaconsfield, Buckinghamshire. A new or improved carriage for locomotion by manual labour.

2452 H. B. Barlow, Manchester. Improvements in apparatus for dressing or preparing hides and for other purposes.

2453 J. Eastwood, Blackburn, Lancashire. Improvements in apparatus for churning milk and mixing liquid compounds, which improvements are also applicable to other purposes.

2454 B. Hunt, Serle-street, Lincoln's Inn. Improved apparatus for spinning yarns of flax, hemp, tow, and other textile materials.

2455 J. Williams, Wigginton Rectory, Oxon. Improvements in maps, and in scientific and educational diagrams to facilitate references and ascertain distances.

2456 M. H. Jacobi, Chancery-lane. An improved galvanoplastic process for depositing iron, applicable for the reproduction of engraved surfaces, stereotyping, and other useful and ornamental purposes.

2457 R. F. Fairlie, Victoria Chambers, Westminster. Improvements in locomotive engines and carriages, and in the mode of coupling the same together.

2458 J. H. Johnson, Lincoln's Inn-fields. Improvements in the manufacture of iron, and in the apparatus employed therein.

2459 W. R. Lake, Southampton-buildings, Chancery-lane. Improvements in penholders.

2460 W. R. Lake, Southampton-buildings, Chancery-lane. An improved machine for making sewing needles.

Dated August 18, 1869.

2461 J. Checketts, Raglan-street, Wolverhampton. An improved window blind.

2462 J. Jenkins, St. George's Wharf, Grand Surrey Canal, Camberwell, Surrey. Improvements in treating and in lining the interior of casks to preserve their contents from the effects of must or other smells arising from the wood.

2463 J. Prato and F. Polacco, Great Winchester-street, Middlesex. Improvements in charcoal filters for purifying water or other liquids, likewise in the mode of applying the same.

2464 J. Mackenzie, Camden Quay, Cork. Improvements in the construction of machinery for sowing seeds and for distributing artificial manure.

2465 E. T. Hughes, Chancery-lane. Improvements in the manufacture of boots and shoes, and in machinery or apparatus employed therein.

2466 A. Brown, Isle of Wight. Improvements in ground or earth screws.

2467 T. Parkinson, Liverpool. Improvements in or connected with doors for regulating the admission of air to furnaces.

2468 E. T. Hughes, Chancery-lane. Improvements in looms for weaving.

2469 R. F. Fairlie, Victoria Chambers, Westminster. Improvements in injectors for feeding steam boilers with water.

2470 J. Lewis, Birmingham. Certain improvements in spring sackings for bedsteads, which said improvements are also applicable to other articles for sitting or reclining on, as also in the joints for connecting and expanding the sides of metallic bedsteads with the head and foot parts.

2471 G. Metcalf, Pertusola Foundry, near Spezia, Italy. Improvements in furnaces for obtaining lead from its ores.

2472 J. Watson, Southampton-buildings, Chancery-lane. Improvements in presses for compressing cotton, jute, and other materials.

2473 J. Mitchell, Sheffield. Improvements in machinery for forging, stamping, tilting, swaging, hammering or planishing metals.

2474 H. W. Cook, Ovington-square, Middlesex. Improvements in turret and other large clocks.

Dated August 19, 1869.

2475 M. Wilson, Wellington-street, Southwark, Surrey. Improvements in bird cages.

2476 J. J. E. Mayall, Brighton, Sussex. Improvements in obtaining motive power, and in the machinery or apparatus employed therein, parts of which improvements are applicable to the forcing and exhausting of air.

2477 W. Campion, Nottingham. Improvements in sewing machines.

2478 A. Gilchrist, Glasgow. Improvements in slide valves.

2479 H. N. Moyon and J. E. Lemercier, Rue Ste. Appoline, Paris. Improvements in machinery for the manufacture of coverings for the feet, together with apparatus and instruments connected therewith.

2480 W. N. Hutchinson, Wellesbourne, Bideford, Devonshire. Improvements in locomotive engines and all descriptions of railway carriages, also for improvements in the form of rail on which the carriages run.

2481 J. Blakey, Leeds. Improved means and apparatus for utilising waste leather, or the small pieces of leather resulting from the cutting out of the several parts for boots and shoes.

2482 F. Braby, Fitzroy Works, Euston-road, Middlesex. Improvements in the means and apparatus for the manufacture of caustic ammonia and ammoniacal salts.
2483 W. Jones, Guide Bridge, Lancashire. Improvements in or applicable to sewing machines.
2484 S. Robinson, Westland-row, Dublin. Improvements in the construction of glass houses for horticultural and other purposes.
2485 J. Jones, Walton-terrace, South Lambeth-road, Surrey. Improvements in apparatus for applying electro-magnetism as a motive power to carriages, boats, and machinery in general.
2486 W. R. Lake, Southampton-buildings, Chancery-lane. Improvements in screw propellers.

Dated August 20, 1869.

2487 W. S. Sutherland, Clayton-square, Liverpool. Improvements in welding or uniting plates, tubes, and other forms of iron or steel, and in means or apparatus employed therein.
2488 A. Wigzell, Sowerby, near Halifax. Certain improvements in steam boilers.
2489 W. Longbottom, Barnsley, and A. Willan, Harrogate, Yorkshire. Improvements in velocipedes and other vehicles propelled by manual power.
2493 W. Byrne, Belfast. Improvements in the process of distilling alcoholic liquors, and in apparatus for that purpose.
2491 H. J. H. King, Glasgow. Improvements in apparatus for measuring, indicating, and regulating the flow or passage of liquids.
2492 L. B. Fortin, Paris, and J. Ferrabee, Brimscombe, near Stroud, Gloucestershire. Improvements in machinery for the manufacture of bats for felting and other purposes.
2493 A. V. Newton, Chancery-lane. An improvement in the process of manufacturing paint.

Dated August 21, 1869.

2494 W. Allan, W. Payne, and A. B. Fraser, Liverpool. Improvements in, and apparatus for, extinguishing fires in the holds or below decks of navigable vessels, whether arising from spontaneous combustion or other cause.
2495 A. Neill, Bradford, Yorkshire. Improved machinery or apparatus for cutting and dressing or producing an even surface on stone, marble, slate, or other substances, also for moulding or shaping and polishing such substances.
2496 G. W. Morgan, George-yard, Great Dover-street, Southwark. Improvements in life buoys.
2497 J. Barlow, Bolton, Lancashire. Improvements in the manufacture of toilet quilts, table covers, and other similar fabrics.
2498 F. Coote, Charlotte-street, Fitzroy-square, Middlesex, and F. W. Cranch, Drummond-street, Euston-square, Middlesex. Improvements in velocipedes.
2499 A. M. Clark, Chancery-lane. Improvements in springs for wheeled vehicles.
2500 P. A. Blake, Highbury, Middlesex. A new or improved safety explosive compound or compounds to be used for blasting and other purposes, together with means connected with its use.
2501 J. Baur, New York, U.S.A. Improvements in the manufacture of steel.

Dated August 23, 1869.

2502 H. Henchman, Bromley, Kent. The improvement of windmills.
2503 T. Gibb and C. Gelstharp, Jarrow-on-Tyne, Durham. Improvements in the extraction of copper from its ores.
2504 N. Delandtsheer, Malines, Belgium. Improvements in combing machines.
2505 H. A. Bonneville, Sackville-street, Piccadilly. A new and useful improvement in machinery for carding and combing wool and other fibrous materials.
2506 L. D. Girard, Faubourg Poissonniere, Paris. Improvements in railways and in railway rolling stock, parts of which improvements are also applicable to other purposes.
2507 T. Whitehead, Holbeck, Leeds. An improved shackle and roller end for hardening machines for felting.
2508 W. R. Lake, Southampton-buildings, Chancery-lane. Improvements in apparatus for raising and forcing water and for obtaining motive power.
2509 W. R. Lake, Southampton-buildings, Chancery-lane. Improvements in posts or standards for gas lamps.
2510 J. H. Johnson, Lincoln's Inn-fields. Producing imitations of, and substitutes for, wood, ivory, stone, and other hard substances applicable to the manufacture of billiard balls and other articles.

NOTICES OF INTENTION TO PROCEED WITH PATENTS.

From the "London Gazette," August 24, 1869.

1100 J. B. Spence
1111 J. Wadsworth

Notice.—Having received communications from persons residing in the country to the effect that difficulties are occasionally experienced by them in obtaining copies of printed specification from the Patent Office, in consequence of the varying nature of the postage thereon, our readers are informed that upon receipt from them of particulars of the specifications they require, together with a remittance for the cost and approximate postage thereof, we shall be happy to procure and forward such specifications free of all further charge. Sums under Five Shillings may be remitted in postage stamps, for sums above that amount a Post Office Money Order should be sent, payable to Robertson, Brooman, and Co., Patent Departmen , 166, Fleet-street, London, E.C. ,to whom all communicat tions upon the subject should be addressed.

THE

MECHANICS' MAGAZINE.

LONDON: FRIDAY, SEPTEMBER 3, 1869.

BRIDGES AND ROOFS.

THE introduction of the railway system, conjointly with the employment of iron on a large and increasing scale, compelled engineers to pay that regard to theory and science which they had never previously done. In all probability but for these circumstances the rule of thumb would have still held chief sway amongst us. As it is, it is by no means so extinct as we would wish to see it. The failure of some of the early iron bridges, and the gigantic structures contemplated in which that material was to play a prominent part, necessitated a careful inquiry into the nature and capabilities of both cast and wrought iron. It is well known that twenty years ago a Royal commission was appointed to enquire into the whole matter. The results of its labours were published in a blue book, which will well repay perusal. Since that time treatises have appeared at intervals dealing more or less lucidly and fully with the subject of iron structures, but even at present our scientific resources on this point are very scanty. Another volume* has been recently added to our *repertoire* by Mr. Unwin, which consists of a reprint of lectures delivered to the members of the Ordnance Corps at Chatham. In the first lecture the subject of shearing strain is investigated, and some very happy graphic methods given for delineating it for any particular case that may occur. It will assist the student if he bear in mind that a shearing strain is always in a vertical direction, and may be said to be the more immediate consequence of placing a weight upon a beam, than the other descriptions of strain. With a load uniformly distributed over a girder, the shearing strain is equal to zero at the centre and is a maximum at the ends over the points of support. With a movable load, its amount and position will vary with the lengths of the loaded and unloaded segments respectively.

There is a point in connection with estimating the correct margin of load upon a bridge that is worthy of notice. Our author justly observes that, whereas some years ago one ton and a half was assumed as the load for a double line of way, now a couple of tons and occasionally so much as two tons and a half are taken by engineers. This is due to the increased weight of the engines and rolling stock of the present day. The point, however, to which we would draw attention is, that there must now be a large number of railway bridges designed upon the former assumption of their load, which are strained a great deal in excess of what was originally intended. Possibly some of them may have been strengthened, but we fancy that is rather the exception than the rule. It is, in fact, not sufficient, as Mr. Unwin points out, to consider the load only when designing a bridge. Attention should be directed to the span and general dimensions of the structure and all the possible positions in which the load may be placed. The position of the load will frequently have quite as much to do with the resulting strain as its absolute amount. It is generally admitted now that tubular bridges are the most expensive type of construction that can be adopted for crossing any intervening space. But although events and the progress of science since the erection of the Menai Bridge may have demonstrated this fact, yet it does not lessen our admiration of the structures themselves, or our esteem for those engineers who designed and executed them in the face of difficulties, obstacles, and prejudices of every description. Considering how imperfect, comparatively speaking, their knowledge of the capabilities of iron was, and how, literally, every step had to be taken in the dark, it is a wonder that so much success was achieved. The cellular flanges have gradually given way to the trough shape, as seen in Charing Cross, Blackfriars, and numerous other railway bridges. Lecture III. concludes with some valuable practical remarks relating to the designing and arrangement of the cross girders of a bridge, a point very rarely paid sufficient attention to. There is quite as much room for design in the cross as in the main girders of a bridge, and a great deal more play for economical planning and adjustment than is usually imagined. Lecture IV. will be found to contain an excellent investigation of the usual forms of braced girders, or those constructed upon the open web principle. The shape of the booms, which include the sectional area of the flanges, and whatever extraneous material it may be found necessary to add to them, is a matter of some importance, more especially as it affects the position of its points of attachment with the web. Theoretically, in order that the strains may be uniformly distributed over the whole flange area, the points of attachment should be so arranged as to pass through the centre of gravity of the section. Practically, a deviation, within certain limits, from this result is of no importance. Moreover, in girders of large span there are other considerations, which would define the shape of the upper flange at least to be such that exact accuracy on this score would not be practicable. So far as the relative economy of the various descriptions of girders is concerned, whatever may be the doubt respecting the different forms of the open-web system, there is none between that system itself and the solid-sided or plate principle. The advocates of the former estimate the saving in weight at fifty per cent., but this probably is a little too high. For small bridges, that is, having a span of about forty feet, it is immaterial which principle is used, as the superior economy of the open web does not appreciably indicate itself in girders of less span than seventy or eighty feet.

It was not very long after the application of iron to girders and bridges that its employment was extended to the construction of roofs, and the gigantic structures at many of our railway stations demonstrate the success that has attended the experiment. Mr. Unwin, in determining the strains upon the principals, commences with the simplest example, namely, that of a pair of rafters, connected at the feet with a tie, and thence proceeds to more complicated cases, including the bowstring and other types of construction. There appears to be some little confusion attending the diagram of stress for the bowstring girder, and there is no doubt the strains could be determined in a simpler manner. We endorse the views of our author respecting the necessity of providing for accidental pressures upon roofs, which do not theoretically act in a vertical direction, but we consider that after including them in the absolute load or weight upon the roof, their further influence is best provided against by properly securing the whole structure with adequate bracing and wind ties. These are points which cannot be regulated by theory. Practice and experience are the only guides to their solution. The best provision against wind pressure lies in the *vis inertiæ* or actual weight of the whole structure. The wind pressure is to some extent a moving load, and its counteraction depends upon the same principles as guide us in the designs of bridges intended for that description of load. In the treatise we have just reviewed numerous plates and woodcuts are added to a clear and well printed text, and the volume is alike a credit to the author and the publisher.

* "Wrought-Iron Bridges and Roofs." Lectures delivered at the Royal Engineer Establishment, Chatham. With examples of the calculation of stress in girders and roof trusses by graphic and algebraic methods. By W. CAWTHORNE UNWIN, B. Sc. Assoc. Inst. C.E. London: E. and F. N. SPON, 48, Charing Cross. 1869.

LIGHT AND OPTICS AT THE BRITISH ASSOCIATION.

REFLEXION OF THE LONG WAVES OF THE SPECTRUM BY FLUOR SPAR—ROCKSALT PRISMS—THE LIGHT OF METEORS—PHOTOGRAPHS OF FOSSIL CORALS—THE ACTION OF LIGHT ON VAPOURS—THE DARK DISCHARGE IN VACUUM TUBES—A NEW HELIOSTAT.

DURING the visit of the British Association to Exeter, several novelties of interest relating to light and optics were brought under the notice of the members. One of the principal of the discoveries was made known by Professor Gustav Magnus, who found out by experiment that fluor spar reflects the waves of ether thrown off by hot rocksalt more than any other polished surface out of the very large list of substances which he tried. Hence if these long waves were visible to the eye, fluor spar would sparkle more brilliantly in such rays than would the polished surfaces of metals. Dr. Balfour Stewart, who was on the platform of Section A during the reading of the paper, called attention to some experiments of his own made a few years ago, tending to prove that the heat rays emitted by rocksalt are very long ones, belonging almost to the extremity of the spectrum. He also found out that, despite the general transparency of rocksalt to obscure heat, it shows great opacity to the heat rays emitted by a second piece of its own substance.

Mr. C. Brooke, F.R.S., narrated to Section A how he and Mr. Browning, the optician, had tried to make rocksalt prisms for use in a heat spectroscope. Supposing the base of the prism to be parallel to the line of cleavage of the crystal, it was found that in nearly every instance the apex of prism split off, and that, as a rule, long before the apex had been ground down to anything like a sharp edge. They therefore thought they would try the influence of annealing upon the crystal, so put one of them in a tin box full enough of sand to well cover the piece of rocksalt, and with a slow and gradual increase of heat, brought it in the course of a few hours to a very high temperature. It was then allowed to cool very slowly indeed. The result of this treatment was to produce pieces of rocksalt which could be ground into prisms without much danger of the splitting of the crystal.

Professor Newton, a distinguished American astronomer, in the course of a speech made at the British Association, said that observations of meteors made in the United States tended to prove that the November meteors burnt up at a much higher altitude in the air than the August meteors. He, therefore, raised the question whether the resisting medium in space which transmits waves of light may not have retarded the lighter fragments forming the meteoric showers more than it retarded the heavy substances. If so, it might be possible that the lighter fragments were formed of different chemical substances to the heavier ones, so burnt up at a higher altitude in consequence. He broached this question, he said, merely as a passing idea, and not as possessing any great weight. Perhaps the spectroscope may hereafter give some information upon the point.

A year ago we called attention in these columns to the method adopted by Mr. James Thomson, of Glasgow, to photograph the bodily organs of fossil corals. Each of these fossil corals is nearly as large as a hen's egg, and Mr. Thomson, it will be remembered, cut a thin slice out of the centre of each coral,

and then ground down and polished the stone slice till it became thin and translucent enough to be used as a negative from which to take photographic prints on paper. When he exhibited these valuable photographs at the British Association at Norwich, last year, Mr. W. H. Harrison recommended him to have them copied in future by the permanent carbon process. Mr. Thomson in consequence went to Newcastle-on-Tyne, saw Mr. Joseph W. Swan, the patentee of the chief carbon process, and made arrangements for a large supply of permanent photographs from the stone negatives. Some of these carbon prints were exhibited at Exeter, and met with much approval. Mr. Thomson says that he and Mr. Swan are now trying experiments upon a new process, which they hope will result in the production of blocks from the coral sections which can be used in the common printing press, to print from in printing ink.

A paper by M. Morren was read by Mr. R. B. Hayward, M.A., detailing some experiments on the action of light upon vapours and gases confined in tubes. The experiments were of the same nature as those performed by Professor Tyndall, wherein the action of a conical beam of intense light from the electric lamp was seen to set up cloudy chemical decomposition in certain transparent vapours from organic volatile liquids. M. Morren, who lives in the south of France, was able to do away with the electric light, and to use sunlight in its place. His experiments were tried with inorganic substances, so as to render easier the task of deciding upon the actual nature of the chemical decomposition set up by light, and in the course of his researches he discovered a source of error in the method of working adopted by Professor Tyndall. The glass experimental tube was of the same description as that used by Professor Tyndall; it had flat ends of glass, fixed to the tube itself by brass ferrules and cement, the ferrules being fitted with stopcocks for the exhaustion of the air. M. Morren introduced a mixture of perfectly pure and dry hydrogen and nitrogen gases into his exhausted tube, and on sending a beam of sunlight through the long axis thereof, he was surprised to see signs of chemical action in the shape of the formation of a cloud. This phenomenon led him to suspect that the resinous cement used to fix on the ends of the tube had perhaps liberated some volatile hydrocarbon to mix with his pure permanent gases. He accordingly made another tube, and used cement free from this objection, but the cloud was formed as before. Lastly, he suspected the arrangement for drying the gases, which consisted of powdered glass wetted with sulphuric acid, and on substituting chloride of calcium as the drying agent, no cloud was formed on the repetition of the experiment. In the end, he found out that even the purest sulphuric acid, quite free from arsenic and other foreign substances, liberates traces of sulphurous acid gas, and thereby causes the formation of a cloud. This fact shows that in some cases, this method of experimenting is a very delicate test for the presence of certain chemical substances. Moreover, the discovery made by M. Morren affects a large number of the experiments on the action of gases upon radiant heat made by Professor Tyndall, and published by him in his celebrated work "Heat Considered as a Mode of Motion." In all those experiments Dr. Tyndall dried his gases by means of powdered glass and sulphuric acid, so that, as shown by M. Morren, traces of sulphurous acid gas must always have been present in his experimental tube, and influencing the result to a certain extent.

Mr. J. P. Gassiot, F.R.S., called attention to a curious deposit of metal in a vacuum tube which he purchased upon the continent. Gradually, as is often the case, a metallic deposit was formed upon the glass round the negative electrode, which was a brass wire, but in addition a number of dark metallic rings were deposited at regular intervals, all along the tube itself. He did not know what gas had been used by the makers to leave its traces in this particular tube. Being one day in the shop of Mr. Cetti, a well-known maker of vacuum tubes, he saw a tube which had been thrown aside as worthless because of the formation of a similar dark deposit. In this latter tube there was an arseniuretted hydrogen vacuum. In both cases he found upon examination that the dark deposit took place exactly in the position of the dark discharge. In Mr. Cetti's tube, wherever the bore was narrowed so as to make the discharge intensely luminous, there was a bright instead of dark deposit of the metallic aluminium of the electrodes. Mr. Gassiot could offer no explanation in either case as to the cause of the phenomenon; he only pointed out the fact.

Mr. G. J. Stoney, F.R.S., exhibited a new heliostat, which he had tested for many months. Without sectional drawings its construction cannot be explained, but it is remarkable for its cheapness and simplicity, and is sure to prove a formidable rival to others in the market.

ON THE REPORT OF THE METEOROLOGICAL COMMITTEE.

THE progress of science suffers no impediment from diversity of opinion, nor from candid criticism. Truth, whether of facts, principles, or laws, however entangled it may be by doubts and discussion while yet only foreshadowed to the scrutiny and intellect of the human mind, will at length become manifest and unassailable for evermore. Thus we shall not be encumbering, but rather assisting, the advance of meteorology by freely commenting upon what is being done in its cause both officially and privately. Few sciences enjoy so large assistance from the State, so greatly do the public desire its development. Hence, as the majority of our readers cannot devote attention to official publications, we endeavour to interest them in the progress and practical application of meteorology by reviewing from time to time the method and results of the work of the Meteorological Office. The Report of the Meteorological Committee for the year 1868 has just been made to Parliament; and from it we learn that the work of the office is distributed under three branches—marine meteorology, telegraphic weather intelligence, and land meteorology.

The office undertakes the duty of supplying the Royal Navy with all the meteorological instruments used in the service, and at the end of the year there were afloat 188 barometers, 416 aneroids, 806 thermometers, 161 hydrometers, &c. The recording of observations with these excellent standard instruments is, however, entirely voluntary on the part of naval officers. It seems that a little reform is required here. The splendid opportunities which her Majesty's ships afford for contributing to meteorological research should be taken advantage of without fail. It is certainly not necessary that every ship in a fleet, nor that ships in home ports, should be constituted observatories for the Meteorological Office; but the flag ship of each squadron and all isolated ships afloat should be. Only about 70 months' observations were sent in during the year by the Navy, while the merchant service returned 259. As it is absolutely necessary that only reliable instruments should be used for the observations desired, captains of merchant ships who volunteer their services are supplied with the requisite instruments; and, at the end of the year, there were so lent, 62 barometers, 12 compasses, 393 thermometers, 254 hydrometers; constituting about 62 floating observatories. We cannot imagine how the committee hope to work up the meteorology of the oceans in anything like a reasonable time with such limited co-operation. They state that the documents already collected are numerous enough for the beaten tracks of the seas; but surely more effort must be made to collect observations where they are said to be urgently required, and we are glad to say the committee "contemplate a more extensive issue of instruments."

"The registers which are in the office are in process of being systematically examined, previous to their being used for the purpose of discussion of their contents. If any register affords internal evidence of inaccuracy, such as a record of barometrical readings which does not exhibit the diurnal range between the tropics, or a series of readings of the dry and wet thermometers which do not differ, or other proofs that it is not trustworthy, it is rejected. By the application of tests such as these, about half of the early registers bearing on the district now under investigation which have been hitherto examined had to be set aside." We cannot understand the grounds of this wholesale rejection for partial faults, and, remembering what Maury accomplished with ordinary ship's logs merely, we feel regret to have had to read this. The work of the office must be mainly of a routine character, such as the reduction of observations, preparation of numerical tables, deduction of averages, &c. Consequently there is little interest in report of progress to the general reader who looks for results. The committee have brought forward and published an atlas of charts showing the monthly mean surface temperature of the South Atlantic, undoubtedly the best work that has yet emanated from the office.* When a public office is allowed to get its affairs muddled, a large expenditure of time and trouble is required to reduce them to order. This has been the case with the Meteorological Office, and the committee very fairly enter at some length into an explanation of the steps taken to rectify account and disposition of instruments. Under the head of telegraphic weather intelligence we have to notice, in the first place, that the committee have recast Admiral Fitzroy's "Instructions for Meteorological Telegraphy," and anyone so disposed can now readily learn the entire plan upon which the observations are made daily at the seaports and transmitted to London, together with directions for using the instruments. The London office is also in communication with the prominent stations on the open seaboard between Cape Finisterre and Bergen. It is, however, found by experience that owing to the geographical position of these islands, weather intelligence of more value can be sent to the continent than can be received therefrom. Heart's Content, Newfoundland, has been a reporting station during the year. The directors of the Anglo-American Telegraph Company very liberally transmit the messages free of cost through their own line, so that the committee have only to defray the cost from Valentia to London. We shall return to this subject in our next.

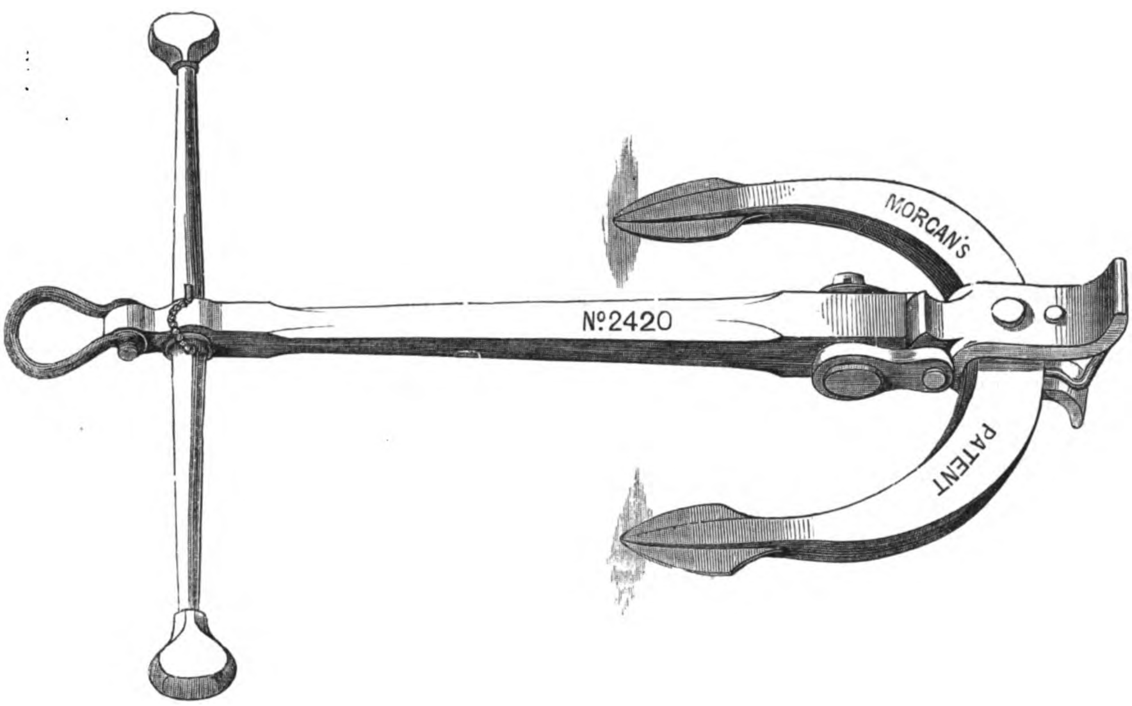
NOTES ON RECENT DISCOVERIES IN SCIENCE AND THEIR PRACTICAL APPLICATIONS.

A PAINLESS KNIFE—GAS IN LIGHTHOUSES—THE METRICAL STANDARDS AND A METRICAL CALENDAR.

AT a recent meeting of medical men, Dr. B. W. Richardson exhibited what he claimed to be a "painless knife." Unfortunately, it fell into clumsy hands, and the mechanism became disordered, so that it could not be seen in practical operation. The invention, however, deserves the attention of mechanicians, who may be able to assist Dr. Richardson in perfecting his instrument. A circular blade, sufficiently sharp and revolving

* See MECHANICS' MAGAZINE for August 14, 1869.

MORGAN'S ANCHOR.



with sufficient rapidity, it seems, gives no pain when it inflicts a wound. The problem is to devise an instrument including the necessary mechanism which a surgeon can hold in his hand and use without difficulty. The production of such an instrument will confer incalculable benefits.

Among recent applications of science we may mention the use of gas in the lighthouse of Howth, Ireland, which has proved so successful that it will probably lead to the employment of gas in all lighthouses to which it can be furnished. Some small works established close to the tower at Howth supply the lamps with cannel gas, and a far superior light is obtained at very much less cost than when oil is used. The burner, which is the invention of Mr. Wigham, of Dublin, consists primarily of three concentric rings, which carry twenty-eight fish-tail jets. These alone give a light two and a half times more powerful than the four-wicked oil lamps previously in use at Howth, and generally employed, we believe, in our lighthouses. Supposing, however, the two lights to be only equal, the saving in cost is over 25 per cent. But, in addition to what we have called the primary burner of 28 jets, Mr. Wigham's apparatus can bring into action several more rings carrying 20 burners each until the light of 108 is furnished. Thus the light can be graduated according as the weather is clear or thick, which was impossible with the old oil lamp. The testimony of all who navigate Dublin Bay, and of the captains of the Irish mail boats, is conclusive as to the superiority of the gas light.

All our readers probably will know that the measurements on which the French metrical system are formed are not rigidly accurate. The error is indeed but trifling, but it was thought sufficient to make it a question whether or not it would be advisable to amend the standard metre and kilogramme kept by the Government. A commission of the French Academy has accordingly considered the subject, and has come to the conclusion that the standard measure and weight now in existence should be retained, and that steps should be taken to present foreign governments with authentic copies of them. The general movement towards the adoption of the metrical system made this a question of interest to the whole world. It is curiously illustrative of the present rage for decimal systems that a Frenchman has just proposed a decimal calendar. We have not yet seen any account of his system, so for the present take no further notice of it.

MORGAN'S PATENT ANCHOR.

THE novelty of this anchor is that it takes the ground with both flukes instead of with one, as in the ordinary anchor. The arms are made to move swivel-like on the shank, so that the palms are always certain to take hold of the ground in whatever direction the anchor may fall on the bottom, or in whatever direction the strain may be on the cable. The stock and the flukes lying both in the same line it is impossible for the pea of the anchor to penetrate the ship's side when entering dock or coming in contact with the pier-heads, as was lately the case with the "Clydesdale" and the "John Bull" at Liverpool. It can be used as well without the stock as with, so that if the stock be broken (an occurrence not infrequent) the biting or holding qualities would not be impaired, and both flukes being down the anchor in shallow water could not damage the ship's bottom in the case of overriding the anchor or grounding. All the parts are made in separate pieces, can be conveniently stowed away, and readily put together when required.

Another important advantage in this anchor is that the several parts are put together without a "weld." The shank is in one piece, having an oval cotter hole punched through it at one end, to which are fastened the two straps, between which "swivels" the "gab strap," and between which again swivel the arms and flukes at right angles, each piece being made without "welds," the whole being riveted or attached by the cotters and bolts, as shown in the drawing.

The extraordinary strength of this anchor has been proved at the Mersey Docks and Harbour Board's Testing Works, Birkenhead, where it withstood the strain of 345 per cent. above Admiralty proof without breaking.

The following is a report of the trial of Morgan's patent anchor, which took place on board the "Scotia," 150-horse power, on Wednesday, August 18, 1869:—

First trial. Off Erith.—Soil, hard coarse gravel. Let go the anchor athwart the tide with a 2½-knot current, boat going through the water at 2 knots. Brought the boat's head to tide immediately; steamed astern full speed without starting the anchor in the least, then steamed ahead with full power over the anchor, and after straightening the chain suddenly brought her up, giving her a great list and pinning her head down about 18in., thus clearly proving the impossibility of fouling the anchor; then steamed again hard astern with the same satisfactory result as before. It was quite evident that in this trial the anchor must have broken ground twice and immediately held again. All on board expressed their surprise and satisfaction at the result of this trial.

Second trial. Off Northfleet.—Soil, hard chalk and flint. Let go the anchor, tide running down very strong, quite three knots. The same experiments were tried as at the first trial with the same results. Everyone on board the vessel expressed their astonishment at the immediate manner in which the boat was brought up over such a bottom. The ordinary anchor could never have got hold in such ground.

Third trial. Off the Mucking Light, Sea Reach.—Soil, soft light mud, and oozey bottom; tide run out. Dropped the anchor and steamed astern full power, the anchor holding immediately; then steamed ahead over the anchor, then astern again, but the anchor held firmly, which was proved by the deep sea lead. It was here determined to try the anchor without the stock, and when it was removed the anchor was again let go; the same form was then gone through by steaming ahead and astern, and, to the astonishment of all on board, the anchor held as firmly without the stock as with.

Everyone being satisfied, and no further proof being required as to the anchor's capabilities, the boat's head was turned for London. In coming up the river a meeting was held by all the practical men on board on the quarter deck; Captain Laing, surveyor to Lloyd's underwriters, took the chair. He said he was deeply gratified with the result of the trials with Morgan's patent anchor. It was impossible that more severe or impartial trials could have taken place. He was perfectly satisfied that the stock was a useless encumbrance to this anchor, and that the holding power, as exhibited, was not in the least degree diminished without it. He also remarked that in his opinion the anchor used at these trials, weighing 7cwt. 2qr. 11lb., was sufficient to have held a vessel of 1,000 tons in any ordinary weather.

These remarks and opinions were endorsed by Captain Champion, surveyor to Lloyd's underwriters; Captain Peters, shipowner and surveyor; Captain Thompson, marine surveyor; Captain Moore, of the "Shipping and Mercantile Gazette"; Captain Newholm, surveyor to Austrian Veritas; Captain E. Little, of the Columbian Navy; Captain Watson, of the Caledonian Steam Towing Company; Captain Newman, of the "Scotia"; and about thirty or forty other gentlemen, representing shipowners, shipbuilders, and others interested in shipping matters. The company were much indebted to Mr. R. R. Edward, the London agent to the Morgan's Patent Anchor Co. (Limited), who, with Mr. Morgan, the patentee, was in attendance to afford every information and explanation required, and personally superintended the arrangements.

PROCEEDINGS OF THE BRITISH ASSOCIATION.

SECTION A.—MATHEMATICAL AND PHYSICAL SCIENCE.

Report of the Committee on Underground Temperatures.

Mr. G. J. Symons read the report of the committee on underground temperatures. He stated that he was only one of the members of the committee, but the duty of the reading of the report

fell on him in consequence of the absence of the Chairman, Professor Sir William Thompson, and of the Secretary, Professor Everett, of Glasgow University. The report set forth that the committee had tried experiments on underground temperatures at Glasgow, Dundee, and wherever they could get access to very deep wells or borings in the earth. But the chief experiment had been tried in a well made many years ago at Kentish Town by a company formed for the purpose of supplying the district with water. The total depth in this instance was 1,032ft., 540ft. of which consisted of a bricked well, and the remainder of a boring lined with thin sheet iron. The well was made first, but as the people in the neighbourhood complained of the hardness of the water, the boring was done, the result being that the supply of water fell off, and the company ruined itself after spending £100,000 on the works. The committee had obtained the use of the old well, and fitted up winding apparatus above it in a hut, to let specially constructed thermometers up and down in the boring. The general result of the experiments was to prove an increase of temperature of one degree for every 52·4ft. increase in depth.

Mr. S. J. Mackie, F.G.S., said that he thought the theory of the internal fluidity of the globe to be untenable. Yet if the increase in temperature mentioned by Mr. Symons continued the same at all depths, at about 450 miles below the surface of the earth, the temperature must be equal to that of the surface of the sun. From diagrams on the wall he noticed that the increase of temperature only became regular after the bricked portion of the wall was passed and the boring reached. He thought that perhaps the conduction of the iron tube would tend to equalise the temperature, and that if the sides of the boring had been rock, irregularities in temperature would have been recorded.

Mr. Symons said that the iron tube was thin—only about one-tenth of an inch in thickness, and 8in. in diameter. It would be a good plan to sink a short length of such a tube in the ground, and to find out whether its conduction of heat influenced the results.

On Secular Variations of Lunar Tints.

BY MR. W. R. BIRT, F.R.A.S.

The author of this paper, in alluding to the importance of an examination of the tints of the lunar surface, remarked that to carry it out in its entirety would entail a most enormous labour, but he recommended that a few of the most prominent objects should be selected for the purpose. He called attention to the fact that changes of tint and brilliancy were common on the moon, as every observer who paid but a slight attention to the subject knew. These changes, he said, were generally referred to variations in the angle at which the sun's light fell upon the object; but he remarked that, although the presumptive evidence is strong this is really the case, it does not come out inductively, because as yet the observations have not been discussed with reference to the sun's altitude and azimuth, as seen from the moon. The author then proceeded to notice certain differences which have been observed between the tints of objects as recently determined and those of the same objects as recorded by previous selenographers, and remarked that we are unable, inductively, to characterise them as resulting from physical change, because the earlier observations are too few on which to found a legitimate conclusion. We have, however, as stated in the paper, the means of obtaining presumptive evidence at least of change of tint, independent of illumination, in the fact that if any two spots be taken, one being brighter than the other according to any particular scale of brightness at a given epoch of illumination or phase, should the order of brightness be reversed at any subsequent epoch, the illumination being the same, the legitimate conclusion would be that a change had occurred in the meantime; and as being unconnected with any theoretical considerations of change, the author suggested the term "secular variation of tint," to designate such phenomena. In the concluding part of the paper the author referred to the number of spots which have been observed during the last forty-nine years on the lunar crater Plato. From records in his possession, it appears that no less than twenty-four spots have, at various times, been seen on the smooth dark floor. Previous to February, 1869, fifteen had been recorded, of which six have been observed recently. In and since February, 1869, nine additional spots have been observed, of which five have been more or less constantly seen by two observers. The remaining thirteen have either become invisible or are but rarely seen.

On the Lunar Crater Plato.

BY MR. W. R. BIRT, F.R.A.S.

In this communication the author stated that certain peaks on the western wall of the crater had been measured by Beer and Madler, the heights varying from 5,000 to 7,000 English feet. These peaks at sunrise cast well-defined long shadows on the floor, and these shadows have been measured by Professor Challis, of Cambridge. The fact of the shadows having been measured left no doubt of the existence of certain irregularities in the shadow corresponding to the irregularities on the summit of the wall. Mr. Birt's collection of drawings of Plato having increased of late, he is able to compare delineations of the shadows by Professor Challis, the late Lord Rosse, the late Rev. W. R. Dawes, and J. Birmingham, Esq., of Millbrook Tuam, and finds some interesting results, among which may be named the proximity of the shadows of the three principal peaks to three very minute craters on the floor of Plato, thus furnishing a means of readily identifying these craters at any future time. In the concluding part of the paper Mr. Birt urged the importance of multiplying such drawings, as a discussion of them in reference to the moon's year may make us better acquainted with the wall itself.

Fall of an Aerolite.

BY DR. NEUMAYER.

Dr. Neumayer read an abstract of a paper recently presented by himself to the Imperial Academy at Berlin, detailing the facts relating to the fall of a meteor a short time ago, at Krähenburg. The fall took place in the day time, and so great was the velocity of the mass that it buried itself 2ft. deep in the sandstone rock. It was dug out while still warm, and found to weigh 31½lb. So great was the noise caused by the rushing of the aerolite at planetary velocity through the air, that it unnerved those people who stood near the spot where it fell, and the sound was heard over a radius of thirteen miles.

Dr. Mann spoke of an aerolite which passed over the colony of Natal, quickly followed by a noise resembling the discharge of a heavy gun; the same aerolite, when seen at another place 120 miles from the first, was also and as quickly heard to produce the same noise; the two reports, therefore, he thought, were not explosions, but sounds quickly produced and lost in consequence of the velocity of the mass.

Professor Newton thought the probability was that it gave two separate explosions.

The Rainfall of Natal.

BY DR. R. J. MANN.

Dr. Mann, in a communication on this subject, said that Natal is, practically speaking, a great inclined plain, with low marshes near the coast, and more and more mountainous as the inland parts are reached. The result of this is that, when the warm steady winds of the summer months roach Natal, laden with vapours of water from the Indian Ocean, the inclined plain forces the moisture-laden air up into colder regions, where it is condensed, and falls again in heavy rains. Floods often occur near the coast, but not in the interior. On the hills the climate of temperate regions is experienced, and lower down the rich vegetation of sub-tropical climates is found. In consequence of its rich vegetation and its fertility, it is a good place for settlers.

SECTION B.—CHEMICAL SCIENCE.

Chemical Nature of Cast Iron.

The committee appointed to investigate the above subject, and which consists of Messrs. F. A. Abel, D. Forbes, and A. Matthiessen, reported that they entrusted the preparation of pure iron to Mr. Matthiessen, who carried out this part of the investigation in conjunction with M. Szizepanowski very satisfactorily. These gentlemen expressed a hope that next year a great deal of very useful information will be obtained on the chemical nature and physical properties of pure iron and its alloys. According to an analysis made by Professor Abel the iron contained in a hundred parts only 0·00025 parts of sulphur. To another analysis the amount of sulphur found by M. Prus. Szizepanowski was 0·0007 per cent. The amount of substance taken for each analysis was about 30 grammes. Phosphorus and silicon were carefully tested by both the above analysts, and found to be entirely absent. Professor Matthiessen then detailed very elaborately the nature and properties of pure iron, and the best and most approved methods of fusion and filtration.

Electrolytic Iron.

BY DR. JACOBI.

Dr. Jacobi read a paper on the electro-deposit of iron. The learned Professor illustrated his remarks by a series of plates of extreme beauty. The solution from which the metallic iron was deposited consisted of a double salt, the sulphate of iron, and magnesia. It was found desirable to coat the recipient of the deposit with a thin film of nickel or copper. Specimens illustrating the application of the electro-deposit of iron to purposes of engraving (aided by photography) were also exhibited.

On the Phosphorescence of Sea and Ozone, in Connection with Atmospheric Conditions.

BY DR. MOFFAT.

Dr. Moffat detailed the results of observations taken at sea to show that ozone is in maximum quantity with decreasing readings of barometer, and the conditions of the south or equatorial circuits of the atmosphere. It is supposed that there might be some connection between ozone and the phosphorescence of the sea.

On the Oxidation of Phosphorus, and the Quantity of Phosphoric Acid Excreted by the Kidneys in connection with Atmospheric Conditions.

BY DR. MOFFAT.

Dr. Moffat stated that from results of observations on the luminosity of phosphorus in connection with atmospheric conditions for a period of six years, it appears that periods of phosphorescence and ozone periods commence, continue, and terminate under the same atmospheric conditions. While the barometer is increasing, and the wind is veering towards the north, phosphorescence diminishes in brilliancy, and ozone increases in quantity, and so on in various quantities, according to the change of wind and barometrical influence. Liquid and gaseous bodies when in contact with phosphorus in a non-luminous state become under certain conditions ozonised. As venous blood contains phosphorus, which in coming in contact with the oxygen of the air is converted into phosphoric acid, and combines with certain alkalies and earths in the liquor *sanguinis*, and forms phosphates of soda, magnesia, and lime, it is not unreasonable to suppose that the quantity of phosphorus oxidated and the phosphates formed in the system and eliminated from it through the kidneys is in some degree determined by the pressure and temperature of the atmosphere, and the state of the weather generally with a view to ascertain the quantity of phosphoric acid excreted by the kidneys. Dr. Moffat tested urine, under certain conditions, viz., that of a healthy man, and by the results it appears that the amount of phosphorus oxidised in the air and the amount oxidised within us depends upon similar atmospheric conditions.

On a Remarkable Structural Appearance in Phosphorus.

BY PROFESSOR TOMLINSON.

Professor Tomlinson said that a very remarkable appearance in phosphorus was seen some months ago by Mr. James John Field, F.C.S., who requested the learned Professor to account for it. Mr. Field placed about half-a-dozen sticks of phosphorus in a cylindrical jar containing water, which rose about half an inch above the ends of the sticks, and the jar was closed with a bung. This jar was placed in a cellar, where it remained undisturbed about three years. The cellar is flagged with stone, surrounded by damp walls, and almost entirely protected from light and currents of air. The maximum temperature probably did not exceed 50deg. or 55deg. Fahr. After this long repose the jar was taken into the laboratory, when it was found that the level of the water had sunk to about one-third of its original height, and the liquid left in the jar had become as dense as the strongest syrup. The portions of phosphorus that rose some inches above the liquid, instead of being cylindrical as before, were conical, from a sharp point to the full diameter, and each cone had a double spiral running down from left to right, as if two flat tapered bands of the substance had been made to cohere at right angles lengthwise, and then twisted into pointed rods, just as if the sticks had been mounted in a

screw-cutting lathe geared to cut a coarse tapering double spiral. The sticks had also changed from the creamy opaque surface to a translucent appearance from the surface of the liquid up to the points. The learned Professor then explained the appearances above described. First, the wasting away of the sticks and their conical form are clearly effects of slow combustion, diminishing in intensity downwards. The continued combustion diminishing, the evaporation of the water must have been due to a badly fitting cork, which during a falling barometer allowed a portion of the moist air to escape from the jar, and, during a rising barometer, allowed a portion of comparatively dry air to stream in. After giving the most conclusive reasons for the spiral markings he concluded by stating that when the particles approach the orifice they converge to a point beyond it; and as this point in the phosphorus to which the relating lines converge, though fixed in or near the tube, is being constantly shifted in the phosphorus by being drawn out and moulded in the tube, the converging lines also are drawn out, and thus give the appearance of a double spiral. Professor Calvert, Dr. Nevins, Mr. Braby, Mr. Wm. Huggon, and Professor Tomlinson took part in the discussion in this Section.

RUST.

BY PROFESSOR CALVERT.

PROFESSOR CALVERT, at the request of the President, gave some interesting results of his experiments into the nature and condition of rust. Oxidation of the bottom of iron ships he thinks may be prevented by an external coating of a preparation of an alloy of lead and antimony, while an alkali is placed in the bilge water within the vessel.

ON THE PRODUCTION OF HIGHER TEMPERATURES BY STEAM OF 212DEG. FAHR.

BY MR. P. SPENCE.

HAVING had occasion to raise large masses of liquor to 228deg. Fahr., for experiment, and as time was of importance, the object of Mr. Spence was to heat the liquors as rapidly as possible. This was accomplished by injecting steam into the mass of liquor, and, as soon as that was obtained, to stop off the steam and to allow the external fire to operate alone so as to raise the additional 16deg., and to maintain the temperature at 228deg. Fahr. The modes adopted, and which the paper detailed, were successful, and it was found that if both steam and fire were left acting after the higher temperature was obtained, the temperature continued, notwithstanding some theories obtained in the experiments as to cooling. After testing the apparatus used with certain solutions the use of fire was discarded, using only steam as a vehicle of heat. Many other operations of this kind were referred to, and it was found that steam sent into large masses of liquor heated them rapidly, and was capable also of dissolving certain salts in a much more rapid and economical manner than by fire.

SECTION C.—GEOLOGY.

DISCOVERY OF FOSSIL PLANTS IN THE CAMBRIAN ROCKS NEAR ST. DAVID'S.

BY DR. HICKS.

IN this communication, the author stated that the strata in which the fossil plants had been found were the Upper Longmynds. Their ripple-marked character showed they had been deposited in shallow water. Last year, Professor Torrell reported his having found land plants in the Cambrian strata, and this encouraged Dr. Hicks to seek for them. He had been successful.

Professor Harkness said that there was a difference in the nature of the supposed plant remains. He mentioned the various theories afloat as to the nature of these plants, and said they might be fucoidal. Some of Dr. Hicks's specimens were, he thought, the tracks of marine worms. Dr. Hicks had sent fossils which were found 1,500ft. below the horizons where they have hitherto been met with in the British islands. They were, therefore, the earliest types of life which had hitherto been found in this country.

Professor Phillips thought that many of the so-called fossil plants in strata of this age might be referred to annelides. He thought the finding of the trilobites and other remains 1,500ft. below the stage they had been found in before ought to teach geologists a valuable lesson. The learned Professor went into an elaborate review of the order of life, succession, and of the natural history classification of the early geological epochs. He thought it the duty of the Association to encourage and support such able workers as Dr. Hicks.

Professor Etheridge said that the plants exhibited were quite of a different character to those shown by Professor Torrell last year. He thought they were nothing beyond furrows or tracks of annelides and crustacea. The number of generic species of trilobites, &c., showed that life was enjoyed in great abundance during these early epochs.

ORGANIC REMAINS IN THE MENDIPS.

BY MR. C. MOORE.

THIS was the report of the committee for the purpose of investigating the veins containing organic remains which occur in the mountain limestone of the Mendips and elsewhere. Mr. Moore has for a long time made the organic remains frequently found in mineral veins his particular study. In his report, he referred to the various theories extant as to the origin of veins. They could not have been formed by sublimation, or the fossils would not be found in them. Mr. Moore was equally against the doctrine of segregation. Referring to Mr. Wallace's theory that many of the veins had been filled up by superficial action since the glacial period, he pointed to the age of the fossils as decidedly against it. Mr. Moore's idea was that open fissures communicated with submarine floors and dwindled down below. The mollusca, &c., of these seas were deposited in the fissures. Three or four things were necessary to the formation of mineral veins—open crevices, the presence of certain minerals in the water of the seas, and electrical action. The Mendip hills are intersected with veins, and on their tops some of these are worked. One of them extends for 270ft. downwards, and contains abundant lias fossils, although no liassic rocks are nearer than several miles away. This proves how great must have been the denuding force. Mr. Moore has also discovered both land and fresh water shells in these veins, as well as entomostraca, as well as seeds of old carboniferous plants. In the mines of North Wales he had found molluscan and fish remains, the latter belonging to no fewer than ten genera. Intermixed with the contents of some of the mineral veins, the author had found innumerable teeth of fishes, *conodonts*, nearly all of which were so small that they required optical power to see them. In the lead veins he had met with great quantities of foraminifera, all of secondary age. These veins also developed the existence of a fresh water fauna, of coal measure age, having no fewer than nine genera, and 127 species.

Mr. H. Brady said three well-known genera of foraminifera had been mentioned by Mr. Moore, all of which still existed. One of the most abundant foraminifera, *Involutina*, was remarkable for its variety of form. Mr. Brady's remarks on the rest of these minute shells were of a purely technical character.

Professor Phillips said Mr. Moore had produced so many new facts that he was entitled to speculate. When he first heard of the discoveries, he was perfectly astonished. What had to be considered in the origin of mineral veins was the altered power of heated water as a solvent to take up and precipitate mineral matter. Mr. Brady's remarks on the alterations in the type of a certain foraminifer were valuable, for, if wide differences could occur in them, why not in animals of a higher organization, such as lions and tigers? He referred to similar changes in the cephalopoda, and expressed his opinion that the understanding of lower types would make us better acquainted with higher forms.

THE WATER-BEARING STRATA IN THE NEIGHBOURHOOD OF NORWICH.

BY MR. J. E. TAYLOR.

THIS paper dealt with the origin of sandpipes in chalk, showing them to be natural drains, and advocating their origin from a chemical point of view. These sandpipes were most abundant in the disturbed chalk, and less so in the solid strata. The latter allowed the water to get away by means of joints and flint bands. The age of some of the sandpipes could be told by the material filling them, and by the unchanged contour of the country. In the excavations attending the sewage works at Norwich, much trouble was given by their having to work through strata thoroughly saturated with water. The same sort of strata standing above the water-level gave no trouble whatever. The deduction was drawn that if so much trouble ensued whilst working only 20ft. below the water-level, the excavation of the proposed Channel tunnel, under so much more pressure, must necessarily be attended with great difficulties. Mr. Taylor gave an interesting statement of the manner in which the wells were drained by the pumping in the neighbourhood of Norwich, and showed they were affected according to the different nature of the strata in which they were sunk.

Mr. Godwin-Austen mentioned several localities in Devonshire where sandpipes occurred in the sandstone rocks, and thought that the chemical theory could not hold in cases like these, although they might do so in chalk districts.

Sir Willoughby Jones expressed his gratification at the papers which had been read, and, as a Norfolk man, said he could thoroughly bear out the correctness of Mr. Taylor's views. It was a very common thing for holes to be suddenly formed by the caving in of gravel and sand into the sandpipes.

Mr. Taylor, in reply to Professor Harkness, said that the upper and lower boulder clays in Norfolk were very distinct. The former were derived principally from the wreck of the lias beds, and the latter from the lower chalk and oolite. One was of a dark blue colour, and the other of an ochreous white.

SECTION D.—BIOLOGY.

ON THE PHYSIOLOGICAL ACTION OF THE METHYL SERIES.

BY DR. B. W. RICHARDSON, F.R.S.

THE author stated that the use of some of these agents had greatly increased during the last twelve months, especially in France; the bichloride had been very safely used, having been administered 2,500 times without any fatal result. With ordinary skill and ability on the part of the operator, insensibility could be produced with about six minims, and in forty seconds of time, which was long enough for all simple operations, and the patient recovered in from three to five minutes. Dr. Richardson alluded to the new substance chloral, discovered by Liebig, the physiological effects of which were about the same as those in the methyl series, but he had not yet examined it himself. The investigation of the alcohols was most elaborately described, and as an anæsthesia the use of alcohol was condemned as being too slow and too prolonged. He could not place the alcohols in any other position than other chemical bodies—they were certainly not foods, nor could they either give strength or supply material for strengthening the tissues, or throw force into the tissue which had been supplied by other matter. It was time that the learned in the profession should recognise the true position of these agents, for seeking force in alcohol was like seeking for sunlight in a subterranean cavern. The report referred to the means of restoring suspended respiration, during which Mr. Richardson exhibited the bellows which he had constructed to aid in restoring respiration artificially. He had, by the aid of the apparatus, restored respiration from two to four minutes after all appearance of it had ceased in dealing with rabbits and other animals, but he could not always succeed, and why he did not he was totally unable to say. A brief discussion followed the report, and in reply Dr. Richardson, speaking of the means used to restore respiration, said that the operator should always have the power to raise the temperature of the room in which he worked, and, as this remark applied to the recovery of the apparently drowned, all receiving houses should contain a room in which the temperature could be raised to 140deg. or even to 160deg. at the will of the operator. There was always in the case of suspended respiration a lowering of the temperature, and the air used in producing artificial respiration should be warmed artificially before being passed into the lungs.

THE LAW OF DEVELOPMENT OF CEREALS.

BY MR. F. F. HALLETT.

MR. HALLETT'S experience showed him several years ago that corn, and especially wheat, was injured by being planted too closely. He found a wheat plant would increase above the ground in proportion as its roots had room to develope, and that the roots might be hindered by being in contact with the roots of another plant. Mr. Hallett continued a series of experiments, planting one kernel of wheat only, and succeeded so well in improving the method of cultivation as to raise wheat whose ears contained 123 grains, or more than 60 on each side. In the course of his investi-

gations Mr. Hallett made other discoveries with regard to the growth of cereals, which he sums up as follows:—"1. Every fully developed plant, whether of wheat, oats, or barley, presents an ear superior in productive power to any of the rest on that plant. 2. Every such plant contains one grain which, upon trial, proves more productive than any other. 3. The best grain in a given plant is found in its best ear. 4. The superior vigour of this grain is transmissible in different degrees to its progeny. 5. By repeated careful selection the superiority is accumulated. 6. The improvement which is first raised gradually, after a long series of years is diminished in amount, and eventually so far arrested that, practically speaking, a limit to improvement in the desired quality is reached. 7. By still continuing to select the improvement is maintained, and practically a fixed type is the result." In the discussion which ensued Mr. Hallett was warmly complimented upon the results he had attained, and the gigantic ears of wheat which he exhibited were examined with the greatest interest by those in the room.

On the Moral Imbecility of Habitual Criminals, Exemplified by Cranial Measurements.

BY DR. WILSON.

The author's theory was that habitual criminals did not possess such an amount of intellect as to enable them to discriminate between right and wrong, and that the majority of them were devoid of moral sense. The habitual criminal was of a low type of intellectual development, and some of them were so backward as to be unable to surmount the rudimentary difficulties of education. The measurements submitted by Dr. Wilson were from 464 separate measurements, and all showed a cranial deficiency, especially in the anterior lobes of the cerebral portions of the brain. Dr. Wilson recommended the adoption of a system of treatment of criminals similar to that in practice in Ireland—a system of punishment more reformatory than punitive, He also suggested that means should be taken to test a criminal, after he had been confined for a certain period, and that if he did not withstand the test he should be for his own sake and also for the sake of society kept in confinement. The discussion which ensued was of a very lively character, and became rather phrenological, till the President announced that there was a paper on that subject to be read on the following day. The President, the Rev. Mr. Caine (chaplain of the County Gaol, Manchester), Professor M'Clellan, Mr. Prideaux, and others, took part in the discussion.

SECTION E.—GEOGRAPHY.

Distribution of Heat on the Sea Surface of the Globe.

BY ADMIRAL SIR E. BELCHER.

The gallant Admiral pointed out that the temperatures which prevail in the Atlantic equatorial currents do not vary much from those in the other or Pacific portion of the ocean; and that north or south, in the Pacific, Arctic, or Antarctic, we find the warmer temperatures prevail more than they do in those regions on our European course into the seas washing Norway and towards Novazembla. That taking certain squares of similarly situated patches in various parts of the world, he thought geographers in general had given too much importance to a supposed warm current, deduced, too, from the equatorial one running to the north-east into the Arctic seas; and having urged that, he sunk the probability of a similar action such as that known to exist in the Antarctic seas. Thus, for instance, south of the Capes Horn and Good Hope, we know that stronger currents prevail in an easterly direction than have been traced in any other part of the world. Assuming a similar law to prevail in high northern latitudes, we can readily account for the flow of a portion of the Atlantic drawn into the vortex without drawing upon the resources of this so-named Gulf Stream.

The Peruvian Expedition.

BY MR. F. F. SEARLE.

This was a narrative of the Peruvian expedition, which was undertaken with a view to the establishment of steam navigation, by Mr. Searle, who was surgeon in charge of the expedition. He gave an account of the expedition from 1862 up to the present time, on the Upper Amazons. He described the expeditions against the Cachibos, who had murdered some officers while on an exploring expedition, and proved that the statements current on the main view of cannibalism prevailing in the interior were well founded. He gave an account of the labours of the Hydrographic Commission, which ascended the Ucayali, to its formation by the Tambo and Wrubamba, and attempted to proceed up the former, but were prevented by the force of the current, but the "Morora," a steamer of 500 tons burden, ascended the Pachitea, within forty miles of Mairo. The settlement of Yquitos now contains over 1,000 inhabitants, of whom 72 are English. The factory is in full work, employing 150 hands, where machinery is produced for private use in the neighbourhood, a floating dock launched, a regular monthly steam communication carried on from Taiatinga, on the frontier of Brazil, to Hurunaguar or the Huallaga River. The climate was favourable for Europeans, labour was plentiful, and the soil fertile. The Peruvian Government will give to emigrants every sort of countenance and protection, grants of land will be given to all who would go out on the sole condition of clearing them within two years, and to skill d labour further advantages will be offered. Much credit was due to Peru for the perseverance displayed in carrying out its object.

Recent Surveys in the Straits of Magellan.

BY CAPTAIN R. C. MAYNE, R.N.

The author gave an interesting account of the recent Government survey in the Straits of Magellan. He glanced at the history of the discovery of the Straits by the first circumnavigator, Magellan, and to the geographical position of the Straits. The Straits are 300 miles in length, and the width varied from two miles at the narrowest to fifteen or twenty miles at the wider parts. In that distance, a complete change of scenery and climate took place. At the entrance, they came upon low prairie land, bare of trees, with a bright sky and fresh wind; but, further on, they came upon mountains rising almost perpendicular from the sea, covered with antarctic evergreen leaves, torrents of rain, varied with snow and hail in their seasons. In some parts, the rain never ceased for twenty-four hours together, and he and his crew had gone for three months without being able to dry their clothes, except at the engine fires. He referred to the great use that was now made of the Straits to avoid the troublesome passage around the Horn. He gave the results of the recent survey, in which he was engaged from December, 1866, to the end of May last. He gave a description of the Patagonians and Fuegans, their manners and customs. The Patagonians were not such giants as represented; he had measured one who was 6ft. 10½in. high, but the average height of the men was 5ft. 10in. to 5ft. 11in., and the women were nearly as large. The Fuegans were small, badly-shaped, and ugly. The Patagonians drank very hard, but the Fuegans would not touch wine or spirit of any kind; on the other hand, the Patagonians would not smoke, but the Fuegans would smoke until they were insensible. The information obtained by Fitzroy as to the Patagonians killing their old people was true; he never saw anybody above a working age. He thought the inhabitants of the region might be very easily educated.

The Gulf Stream.

BY MR. A. G. FINDLAY.

In his paper on the supposed influence of the Gulf Stream on the climate of North-West Europe, Mr. Findlay submitted that the actual bulk of water which passes through the Florida Channel is from 294 to 330 cubic miles per day, and it receives no accession from the tropics. Fully one-half of this passes eastward and southward from the banks of Newfoundland, and the northern half, cooled down and neutralised by the Arctic current, has, according to this theory, to cover this area to raise its temperature. The known bulk of the Stream will only give six inches per diem over this area. And he would ask, how is it possible that such a minute film could have any influence, and this, too, at from one to two years after it has left the Gulf of Florida as the true Gulf Stream? He would not advert to the further progress of this warmer water, which might be traced to and beyond Spitzbergen, and its effects throughout the North Polar Basin, and these effects, he contended, were totally and absolutely incompatible with the now well-known particular of the Gulf Stream proper. He could not go into the isothermal lines, which show most markedly the higher temperature in the winter and much less so in the summer. The equable temperature of the waters causes this change—the relation of the warm and cold water. It had been propounded by Mr. Crott that the modern method of determining the amount of heat would account for all the phenomena popularly attributed to the Gulf Stream. But he (Mr. Findlay) would deferentially demur to his calculations. Mr. Crott took no account of the time it takes for the water to circulate. He doubled, as he (Mr. Findlay) thought, the volume of the Stream, and he took no account of the interferences it encountered. However valuable his suggestions might be, they must be applied in a different way. How, then, can the phenomena of our warm winter climate be accounted for? The reason seemed to him to be simple and obvious. The great belt of south-west winds called the Anti-trade, or Passage winds, passes over the North Atlantic throughout its breadth, and drives slowly the whole surface of the water to the northward of an easterly course or towards the shore of North-West Europe. From the particular configuration of the land, this north-west drift is allowed to pass into the Polar area. This south-west wind infuses into high latitudes the temperature and moisture of much lower parallels, and by its greater rate of travelling passes over the warmer water to the southward, and this brings to Exeter in one day the warmth of the centre of France. By its variation from westward or eastward of a southerly direction, we find all the variations or moisture which is induced by this wind passing over land or sea. The excellent observations made in the expedition from the Royal Society, under Dr. Carpenter and Dr. Wyvell Thompson, would, he had no doubt, throw great light on this obscure north-east current, which should not be called the Gulf Stream, but possess a specific term.

SECTION F.—ECONOMIC SCIENCE AND STATISTICS.

Education of the Agricultural Labourer.

BY THE REV. CANON GIRDLESTONE.

Canon Girdlestone, in his paper on the Maintenance of Schools in Rural Districts, said another twelve months had confirmed him more strongly than ever in the opinions he had expressed at Norwich last year, on the condition of the agricultural labourer. He had advocated and promoted emigration as a mere palliative, and with great success; but he looked to education as the only permanent means of improvement. After referring to the general expectations that something would be done in Parliament next session, in the direction of the compulsory education of children of the agricultural labourer, he urged that such a measure would be unjust and useless until the establishment of really efficient schools within easy reach of every cottager's door, which was far from being the case now in more than half the rural parishes. In 14,877 parishes in England and Wales, there were only 7,406 aided schools; of the remainder, 2,779 were schools built with State aid, but not fulfilling the conditions of annual State aid. With regard to 4,692 parishes nothing whatever was officially known, but there were, no doubt, good schools in some of them. The Rev. Canon proceeded to explain the cause of the deficiency. The difficulty did not consist in the first effort to build a school, but in the continued effort required in its maintenance. This was not owing to poverty in the parishes themselves. The rate-books showed that there was sufficient property in each to maintain an efficient school by a tax so small as to be almost inappreciable. The clergy did their part, not only in the schools themselves, but in the disagreeable task of collecting subscriptions from parties many of whom altogether refused to do their duty, while not a few treated the clergymen with rudeness. Then, while some landlords were very generous, especially if the school were near their own residence, yet as a class, especially if non-resident, the landlords almost entirely ignored the claim which the cause of education had upon property, and the occupiers of land contributed hardly anything at all. Those were facts, proved by official documents. There could never be any guarantee for the existence of an efficient school within easy access of every labourer until the land was made to do its duty. He recommended that the children should continue to pay a penny a week; that the State grant should be contributed as now; that where there were not efficient schools such schools should be built with money borrowed wholly on the parochial rates; that Denison's Act should be made compulsory, and so throw upon occupiers of land the charge of educating the children of out-door paupers; and that the money now raised by voluntary contributions should be collected in the form of a tax or rate upon land. If

this cost a million, a rate of 2½d. in the £ would raise the money, and a 1d. in the £ would probably be sufficient. Thus, the landowners would be made to pay a fair share, the occupiers, under the operation of Denison's Act, would pay a small share (being already heavily burdened), and professional men and others would contribute their share through the general taxes towards the State aid. There would still be enough for voluntary beneficence to do in supporting Sunday schools, and extra books, maps, libraries, presents, and superannuation allowances to deserving teachers, and helping poor children to clothes to go to school in, &c. Towards the conclusion the Rev. Canon quoted the words of Mr. Howard, Her Majesty's Inspector of Schools in North Devon:—"At present the chief burden of the support of schools is borne by the clergy; the farmers, as a class, give nothing; the contributions of the country gentlemen are shamefully small."

Mr. J. Bayley Denton immediately followed with a short paper on Technical Education of the Agricultural Labourer. He advocated a system by which, along with primary education, information might be imparted to the children of agricultural labourers on such matters as the animals, insects, and crops on the farm, and the teachers should be qualified to teach children matters connected with the business of their future life.

THE SUTHERLAND GOLD DIGGINGS AS A SCIENTIFIC AND SOCIAL EXPERIMENT.

BY DR. L. LINDSAY.

DR. L. LINDSAY'S paper on this subject was taken as read. He had laid it down as a fact at the Dundee Meeting that a great portion of the area of Scotland, including Sutherland, is auriferous. Lately Mr. Robert Gilchrist had made successful experiments in raising gold in Sutherland. The object of the present communication was to show the extent to which these diggings had already proved successful and beneficial, the character of the difficulties that have been overcome, and the obstacles that still stood in the way. In conclusion, he said there was every reason to believe that many other parts of Scotland were quite as auriferous as Sutherland, and to those the attention of the gold diggers should be turned if the existing obstacles at Sutherland were not speedily removed.

THE DECLINE OF SHIP-BUILDING ON THE THAMES.

A PAPER by Mr. John Glover was read on this subject. He attributes the great decline in this branch of business in the metropolis to the fact that the cost of one day's work of a ship-carpenter, a joiner, plater, caulker, riveter, sail maker, boiler maker, engineer, turner, and pattern worker, is on the Thames, 72s.; on the Clyde, 58s. 8d.; and on the Wear, 55s. 8d. The extra cost of labour on the Thames was, he contended, alone sufficient to account for the decline of the trade. The establishment charges on the Thames were reported to be double those on the Northern rivers. There were some minor causes tending in the same direction. The comparative disuse of wood, for example, in the building of ships was disadvantageous to the Thames ship-builder. Then why did not the wages on the Thames fall to the Northern level? Because the trades unions fixed an artificial standard, and they destroyed the trade.

SECTION G.—MECHANICAL SCIENCE.

ON ROADS AND RAILWAYS IN NORTHERN INDIA AS AFFECTED BY THE ABRADING AND TRANSPORTING POWER OF WATER.

BY MR. LOGIN.

THE author commenced by stating general conclusions he had arrived at to the effect that the abrading and transporting power of water was increased directly as the velocity and inversely as the depth; also, that when flowing water had once got its proper load of solid matter in suspension all erosive action ceased. In short, that it was like a balance, the load being always equal to the power, which power, somehow or other, increased as the velocity became greater, and decreased as the depth of a stream increased, Nature always adjusting the load to the various circumstances. He then gave a short description of the plains and rivers of Northern India, and, by the aid of diagrams, went on to argue that rivers flowing through alluvial plains were raising rather than lowering their beds, and, though this silting up process may be very slow, yet it was satisfactory to the engineer to know that the foundations of his bridges would be as safe, if not safer, a hundred years hence, as they are now. In speaking of the changes of the courses of rivers, he said that there was more or less a constant cutting going on on the concave banks of a river, with a silting up process on the opposite side.

The next subject referred to was the denudation of the high-level plains of Northern India called "Doabs" (two waters), and locally known by the name of "Bhangar" land, in contradistinction to the term "Khadir," or low valley lands, through which the large rivers, fed by the melting snows, now meander. Mr. Logan said that the higher ridges or "back bones" of these Doabs were not caused by any upheavals, but were formed by the denudation of these high-level plains; and, as the rainfall was three or four times as great in the valley of the Ganges as that of the Indus, these back bones in the plains of the Punjab disappeared, as well as all defined drainage lines some fifty miles below the hills, for the simple reason that the water spread over these plains and was absorbed. To this peculiarity in the Punjab, particular attention was drawn; for Mr. Login argued that, if standing crops and grass could permit without receiving injury the rain which fell higher up to flow through rather than over those standing crops, surely the same water could flow over an iron rail at very slow velocities, seldom, if ever rising to such a height as to interfere with a locomotive passing over the line; however, if it did, the obstruction could only last for not more than one day in a whole year. By acting on this principle, Mr. Login believed that hundreds of thousands of pounds can be saved in the construction of railways in Upper India, as no embankments or masonry culverts and bridges would be required in crossing such high-level plains as the Bechna Doabs, which he had surveyed; while pounding back these flood waters by embankments, and forcing it to find an escape through culverts, was most costly and dangerous, for it increased the abrading and transporting power of the water at the very point where alone it could do injury, namely, where it crossed the rails.

In support of his argument he quoted actual occurrences. He urged that deep foundations for bridges was the proper mode for spanning the large rivers of India, and that only one opening for both the main stream and the inundation water should be provided, while any little water that might be left behind in the swamps or low ground which is below the level of the main river, should be drained off by spoon-mouthed syphons. Speaking of the minor torrents, he briefly referred to another description of bridge, resting on inverts, with deep massive curtain walls, which may, with economy, be introduced in some instances; and concluded by stating that once the abrading and transporting power of water was more fully investigated the engineer could proceed with all descriptions of works affected by flowing water with greater confidence and economy, instancing harbours on the Madras coast, which province, from being at present a financial loss to the state, would soon become profitable, both to India and England, by increased commerce.

UTILISATION OF TOWN SEWAGE.

BY MR. T. D. BARRY.

AFTER expressing an opinion adverse to the application of Mr. Moule's dry system to large towns, the author proceeded to criticise the irrigation system, especially as developed at Edinburgh, Worthing, and Croydon, and contended that fields subjected to constant irrigation can produce nothing but rank coarse grass, and that if any other crop is to be grown in those fields, the flow of sewage must be discontinued. Indeed, unless this was occasionally done, he did not think irrigation would benefit land. The effects of irrigation were most beneficial on clay and sandy soils, and really good land did not give evidence of so much improvement. He could see but little difference between the effects of sewage irrigation and the pure water irrigation in Lombardy and Piedmont. The advocates of irrigation claimed that their system possessed two advantages, viz., freedom from offensive smell, nuisance, or injurious influence on the health of a district, and a remunerative return for money laid out. He proceeded to dispute both these propositions. With respect to the latter, he argued that the apparent success was due to accidental circumstances, and had no permanent reality, and brought forward several illustrations in support of his views. He also argued that the system was not so free from nuisance, &c., as was claimed for it, and quoted authorities on the matter, and then proceeded to contend that the land was deteriorated by repeated and successive applications of liquid sewage. He expressed his adherence to the system of filtration as more suited to certain localities and large towns. He explained that, at Leamington, the town ashes, road scrapings, &c., were mixed with the sewage, and a dry manure formed which found a ready sale among the farmers, produced good crops of all kinds of vegetables, and was prepared without any offensive or unhealthy odour.

Dr. Paul said the works at Leamington were satisfactory, as far as the eye went, but it was illusory. Only about one-fourth of the manure was taken from the water, though it seemed perfectly clear. Four per cent. of ammonia was the only component in the manure produced at Leamington which was of any value, and at places where much manure was produced, it was sold at from 6d. to 2s. per ton. With regard to the question of profit and loss, he held that the towns must be expected to pay for getting rid of their refuse, and the real profit was the improvement of the land. He did not see the greater danger to health of spreading the sewage on the land than of pouring it into the water we drink.

Mr. Rumney said it had been stated that either irrigation or filtration must be adopted. This he denied, and explained a plan which is being adopted under the Artisans' Dwellinghouse Act at Manchester which he thought preferable to either.

Mr. Hope, of the Barking Sewage Farm, joined issue with Mr. Barry, and defended the judicious use of liquid sewage, and said that where it had parted it was due to mismanagement.

Mr. Stanford compared a company looking for profit from the deposit of sewage to a ferret watching one hole of a rabbit burrow while the rabbit ran out of the other. Irrigation was not adapted to all towns, and he thought it better to make sewage solid by mixing it with something else, and carrying it away, as in Manchester.

Admiral Belcher said that in China and Malay the excreta is allowed to be in proximity to the houses, but no malaria resulted; but if water was allowed to flow over it, fermentation would ensue, and bush fever would follow. The drainage system which we have adopted robbed the land of the fertilising salts, and conveyed them to the rivers. He was the originator of the Thames Sewage scheme, and he had suggested that the outlet should be extended through Essex, and be delivered by the River Crouch into the German Ocean.

Mr. Barry said he was afraid the dry system mentioned as in operation at Manchester would not answer, because of the difficulty of administration, and the annoyance and danger of carrying the excreta through the houses.

SEA-GOING SHIPS.

BY MR. C. W. MERRIFIELD.

MR. MERRIFIELD read extracts from the report of the committee on the state of knowledge of stability and sea-going qualities of ships. The report treated at considerable length on the rolling of ships in still water, followed by an account of the mechanism of waves and an abridgement of what is known on the subject of the rolling of ships in wave water. The report itself being, in reality, a very condensed abstract of our existing knowledge, it would be difficult to make a useful selection for reading. Meanwhile, it may be stated in general terms that the rolling of a ship in still water, and her behaviour in a seaway, although interdependent, involve very divergent conditions. It seems that the chief point to attend to to secure easy rolling is that the natural period of the ship's oscillation should not coincide, or nearly coincide, with the period of the waves, and there seems reason to suppose that we already know how, in a rough way, to influence the natural periodic time of the ship, so as to be able to predict nearly in what waves she will and in what waves she will not roll through excessive angles and with excessive quickness. But our knowledge is exceedingly crude and deficient in detail, and even our known means of observation of the height and form of waves are very unsatisfactory. He also read several reasons by Mr. Froude for not agreeing with the committee.

THE Duke of Cambridge has conferred the new appointment of military controller in the Chatham district on Assistant-Commissary-General W. Fulford Adams, who has entered on the duties of the office. Assistant-Commissary-General Thomas E. M'Clintock, who had previously been named as having received the appointment, has been ordered by the Field-Marshal Commanding-in-Chief to assume the duties of paymaster only for the Chatham district.

IMPROVED HARVESTING MACHINE.

BY MR. J. T. GRIFFIN.

FIG.1.

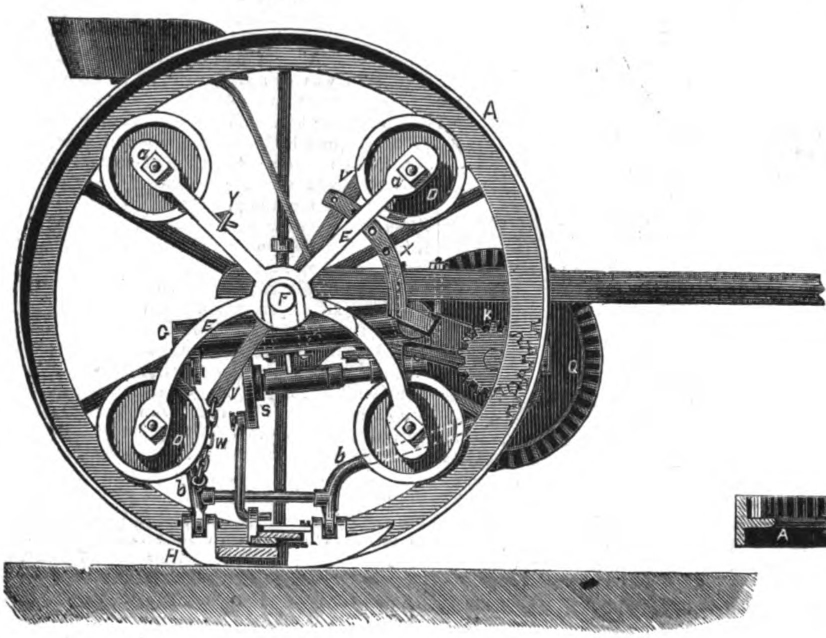


FIG.2.

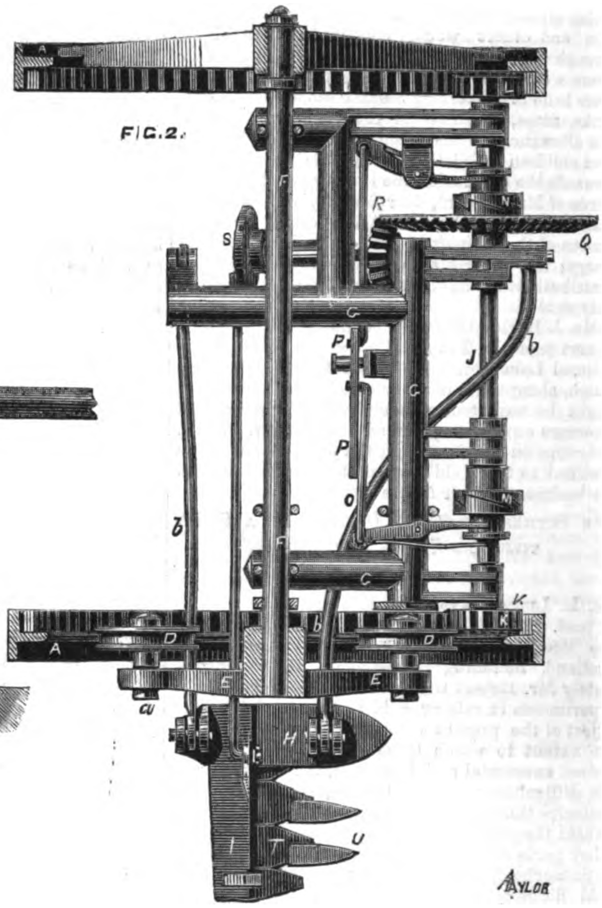


IMPROVED HARVESTING MACHINE.

THE principal feature of the invention we are about to describe is an improved arrangement of the frame and parts connected with it in machines in which the finger beam is fitted in a line with the axle of the main driving wheel. The finger beam and cutters are connected to bars or supports which pass through one of the main driving wheels, which is supported upon rollers attached by bars to the main axle. The main axle is rigidly fixed to the frame. The driving wheels are each made with an internal rib or feather; the rollers bear upon or against the rib of one of the wheels; the insides of the rim of the wheels are formed with teeth for pinions to work in, which drive or operate the cutters.

The bars or supports for the finger beam are jointed to the main frame, so that they can be raised and lowered by means of a chain and lever placed within reach of the driver, in order to regulate the height of cut, the lever being held in place by a bolt passed into holes in a quadrant. The axle on which the pinions are mounted is furnished with two clutches, the forks of which are connected to one hand lever, so that both can be thrown into and out of gear simultaneously. The shoe of the finger beam is jointed to the supporting bars, in order that it, with the beam and cutters, can be turned on end when the machine has to be moved from place to place. The pitman and cutters are driven in the usual manner.

The invention has been patented by Mr. J. T. Griffin, of 77, Upper Thames-street, London. In our engravings, fig. 1 is a side elevation of a harvesting machine constructed upon this principle; and fig. 2 is a plan view of the working parts, with the main bearing wheels in section. A A are the wheels, upon which the whole weight of the machine is borne, and by which the mechanism is caused to act as the machine travels. The inside of one of the wheels has a rib or feather C for running upon rollers D D, which are pinned upon axles *a a* of a frame E fixed on one end of the main axle F; this axle carries bars or connections G G, to which the rods *b b* for supporting the shoe H and finger beam I are fastened, and which are in a line with the main axle. There are projecting pieces on the front of the bars G G for carrying a shaft J, upon which are mounted the two pinions K L, which receive their motion from the teeth of the wheels A A; each end of the shaft J is provided with a clutch arrangement M N and levers O P, so that one movement of the lever P throws both of the clutches into or out of gear as required. The upper end of the lever P is brought within reach of the driver, so that he has perfect command over the working of the machine. The shaft J has a bevel wheel Q mounted loosely upon it, and when the clutches are in gear this wheel Q acts upon the bevel pinion R and causes the pitman S to revolve, whereby the cutters T T are drawn to and fro in the beam I in a rapid manner, and by their working in slots formed in the fingers U the grass or other crop is operated upon and severed from the roots.

The height at which it is determined to cut the crop above the ground is regulated by the lever V, which is connected to the shoe H by a chain W. The upper end of the lever works in a quadrant or rack X, and on a bolt being passed into one or other of the holes in the quadrant the lever is held secure. The rods *b b* are pinned or jointed to the shoe H, so that the shoe and finger beam may be turned up in a vertical position to enable the machine to pass through gates or narrow passages into the field in which it is desired to work it. When the finger beam is in a vertical position it is held secure by a spring catch Y, fitted to one of the arms of the rollers D D, and by the clutches being out of gear the main wheels and their pinions rotate without communicating the motion to the cutting mechanism.

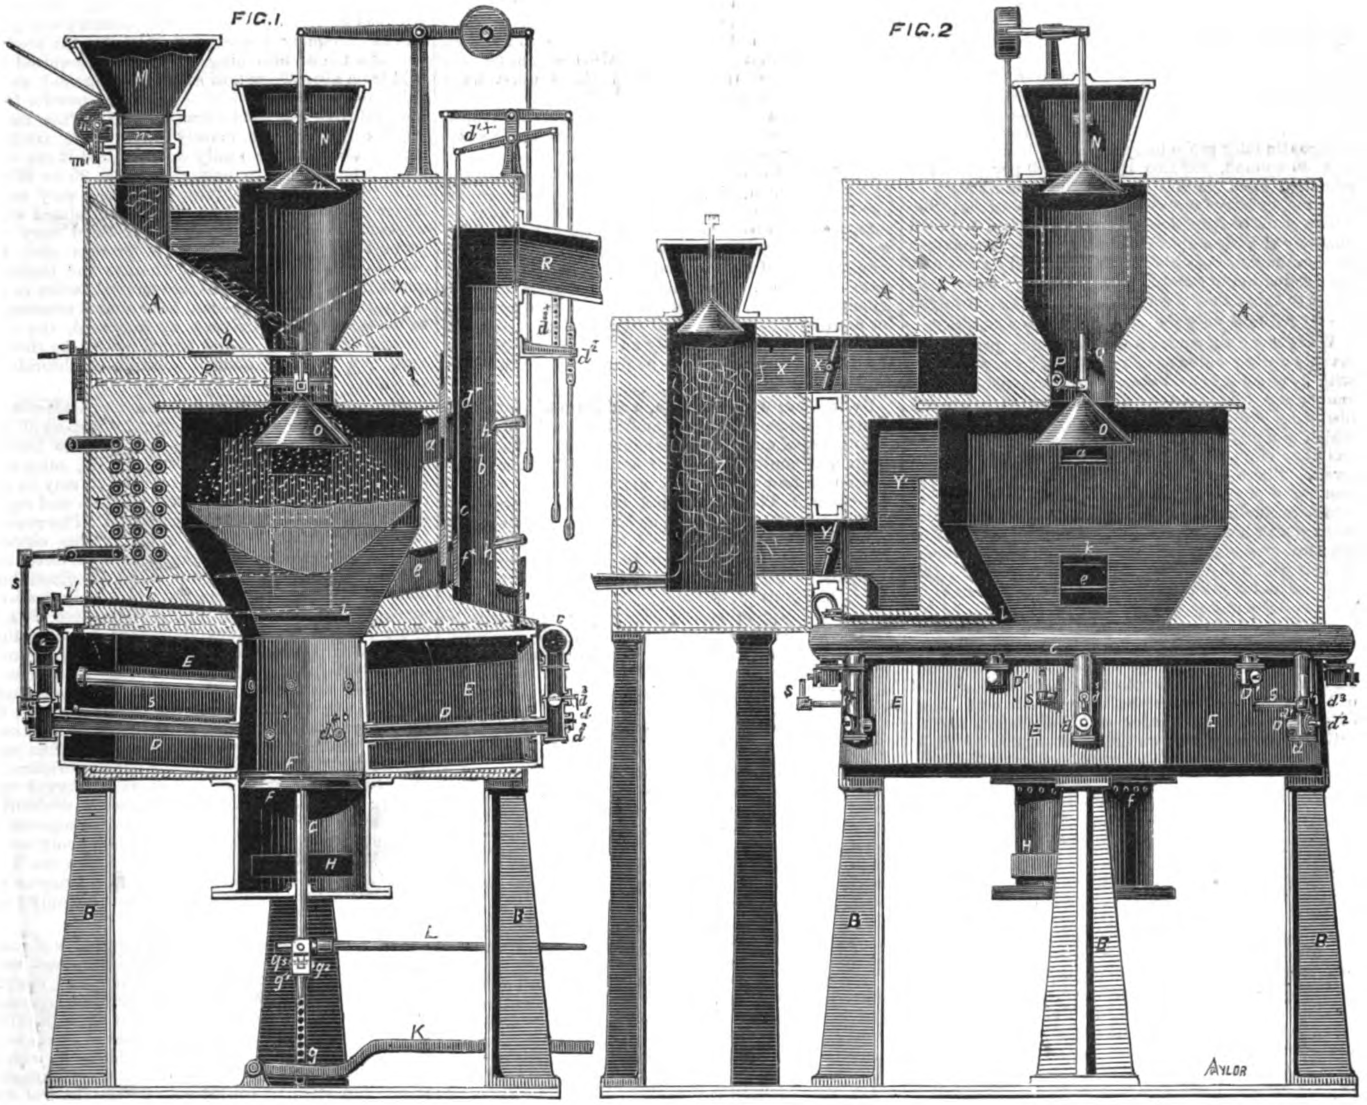
APPARATUS FOR PRODUCING COMBUSTIBLE GASES.

MR. G. H. BENSON, of Staleybridge, and Mr. W. G. Valentin, of the Royal College of Chemistry, have patented some improvements in generators for producing combustible gases. These generators are applicable to various kinds of fuel, but our engraving shows at fig. 1 a transverse vertical section of a generator for free-burning non-caking coals, fig. 2 being a longitudinal vertical section of the same with the purifier attached. It is a close apparatus A A, consisting of a casing of wrought-iron plates supported on cast-iron standards B B about 6ft. from the ground, and lined with firebrick, a bed of sand being placed next the plates to keep all gastight. The air to support combustion is supplied in the form of blast produced by a blast engine, and is brought from the engine by a pipe to the air main C C. This air is heated by the waste heat of the furnace. From the air main C are separate connections to each of the tuyeres D D [1], which are placed at equal distances round the generator. These tuyeres are strong wrought-iron pipes fitted into cast or wrought-iron boxes E filled with water. These boxes may be either open or close vessels, and are in connection with a reservoir, which will supply the water evaporated from them. These boxes form the lower portion of the generator in which the carbonic oxide is produced. The lower tuyeres D or "soder" tuyeres act on the partly burnt coke and ash, and reduce it into a semi-pasty-like mass, called "solder," which will run away into the lower portion of the cylindrical chamber and allow fresh fuel to fall to the tuyeres. The top row or gas tuyeres I [1] convert the coke into carbonic oxide and act freely, as solder will not have time to form and obstruct them, but should any form, it will be rapidly pressed down by the fuel above aided by the action of the tuyeres below. A portion of the gas made below is ignited by the air from these gas tuyeres, but is converted again into carbonic oxide by passing through the layer of hot coke above the gas tuyeres.

In the generator there are six top tuyeres and six bottom tuyeres placed at equal distances round the generator, but not in a line above each other. The tuyeres pipes at the outside of the water boxes turn up, and at the angle are placed boxes *d d* for holding any solder that may stick to the poking bar on withdrawing it after poking the fire. This requires to be done about once every fifteen minutes. These boxes *d* can be emptied through the sliding door below. The top tuyeres do not require these boxes, as any solder that may be formed may be pushed inside. The poking bars are introduced through a sliding door d^1 at the end, or by withdrawing a plug d^2 in the door d^1. Each tuyere is provided with a separate tap or valve d^3, so that the volume of air can be changed and regulated as may be required. Where the tuyere pipes touch the fuel they may be contracted by a nozzle d^4, which can be easily removed from the outside through the tuyere pipe when not required. The refuse ash, clinker, or "solder" made by the melting of the dirt in the fuel falls from the tuyere mouths on to the movable plate F, and when the space is filled with a fused mass which impedes the working of the solder tuyeres, the plate F is lowered 2in. by altering the position of the peg *g* in the rod G a hole higher so as to let the plate down.

APPARATUS FOR PRODUCING COMBUSTIBLE GASES.

BY MESSRS. G. H. BENSON AND W. G. VALENTIN.



In about twenty-four hours, the whole space in which the plate F works will be filled up with "solder." The air must then be shut off, and horizontal bars are introduced through the holes *f f* so as to hold up the fuel. The solder can then be withdrawn through the door H, as it will be cold and brittle and will not stick to the smooth iron as it would to brick. The plate F will then be placed in its original position and the bars withdrawn from the holes *f* and all made tight by means of a closely fitting door, and the generator will again be in working order.

In the usual generators the operation of clearing away the solder causes considerable interruption several times a day, but in this generator it is effected in a few minutes, leaving the generator quite free from solder, except a thin layer to protect the movable plate F. This plate is provided with a scraper I to keep the plate in position and to scrape off any pieces of solder which might otherwise fasten the plate for a time against the tuyere boxes and thus impede its free working. The plate F can be easily moved up and down by means of the lever K, so as to break up any holes in the hot fuel and prevent the air from passing through the coke without forming gas. It will also prevent any solder from sticking to the boxes E, which would cause the fuel to remain up and not fall gradually to the blast. The movement of the plate F will thus save poking the fuel above, which is an evil, inasmuch as it disturbs the action of the slow distillation. Just above the pin *g* the central rod G of the plate F is divided into two parts, and is fitted together by a socket joint [1], so that by withdrawing the connecting pin *g* [2] it can be turned round by a lever L fitted into a projecting pin *g* [3] on the socket *g* [1] so as to bring a different surface of fuel to the action of the blast. The bottom plate F can be made to revolve once every hour, and when it is wished to stir the fuel the pin *g* [2] can be inserted and the plate F can be raised once or twice; but in practice, with the right sort of fuel (and if the tuyeres are kept open) this is very seldom required.

The fuel is fed into the generator either by a hopper and plug arrangement, as at N, or by a feeding apparatus M, which consists of a rotating wheel *m* fitted with wings, and made to rotate in a box or cylinder at the bottom part of a hopper, so that at every sixth part of a turn of the feeding wheel *m*, a portion of the fuel will be dropped into the generator. The wings of the rotating wheel fit at the bottom gastight, and are fixed on a shaft which carries on its end a worm wheel *m* [1], which is driven by a worm *m* [2] fixed on a shaft driven by the engine. By this means a regulated and continual stream of coal is always dropping into the generator. The hopper and plug arrangement seen at N is not used, except when first starting the generator or for letting in large quantities of fuel at a time. It is provided with a close top to prevent the gas from escaping when the plug *n* is lowered. The fuel from the feeder falls on to a conical plug O, which will spread it equally all round the generator on the surface and to the outside of the previously filled fuel. This plug is moved up and down by means of a rod P provided with a lever which acts on the stem of the plug O. The outer end of the rod P is provided with handles for turning it, and is fitted with a ratchet and catch to hold it in position. The plug O is moved backwards and forwards laterally by means of a rod Q.

The fuel inside the generator forms a sort of circular inclined plane or hollow inverted cone, the lower portion of which is being slowly distilled off and gradually sinks to the hot fuel in the centre, the fresh added fuel taking its place at the top of the plane. The raw fuel by falling to the outside prevents the air from stripping up the sides and so lighting the gas at the surface; it also prevents the brickwork from being eaten away. The hydrocarbon and carbonic oxide gases are passed direct to the main pipe R or through a purifier, which we shall presently explain. When sent direct to the main R, the gases escape by the opening *a* into a vertical flue *b*, which opening *a* may be closed by a valve *c* worked by the rod *d*[a] and lever *d* [1a], and may be held in position by a pin *d* [2a] in the pendent rods *d* [3a]. Below the surface of the fuel there is another exit aperture *e* provided with a valve *f*[a] which is worked by the same rod and lever as the valve *c* above. This lower aperture *e* is called the carbonic oxide flue, and it is used when the top fuel is becoming too much burnt through, or to stop a sudden flush of gas. Should a sudden evolution of gas occur, these evils are prevented without stopping the volume of gas or arresting the blast or stopping the action of the feeder. This is effected by simply raising the rod *d*[a] and shutting the top fuel *a*, at the same time opening the bottom flue *e*, and thus forcing the gases to descend through the hot fuel, whereby the tarry matters being obliged by pressure to descend will be converted into gas, and the flame will be clear and the volume of gas the same in the furnace as if nothing abnormal had occurred. When the sudden flush of gas is over, the valves are replaced as before and all goes through the opening *a*.

In addition to the valves *c* and *f*[a], there are stop valves *j k*, worked by a lever and rod for regulating the amount of gas to the furnaces. The two flues *a e* being exactly of the same size, each can be partly closed without interfering with the action of the carbonic oxide valve arrangement. The upper part of the generator forms a reservoir for gas, and thus prevents intermittent supplies of gas to the furnaces, if from any cause the generator should cease temporarily to produce the regular supply. It also keeps the tarry matters in the generator, and prevents it from filling the pipes and choking them. Poking holes *l l* are made in the form of long slits, and are placed at various heights in the generator. These holes or apertures are provided with air pipes *l* [1], the blast from which will prevent the escape of gas through the holes and will protect the hand of the workman from the flame that would otherwise issue. Steam can also be introduced by the pipe S, and this steam may be superheated by passing it through pipes built into the brickwork as at T.

THE attempts to employ naphtha as fuel have at length proved successful. On July 31 a train arrived safely in Kutschujan, 81 versts from Charkoff, whose engine was heated with raw naphtha instead of coals. The honour of the invention is ascribed to the mining engineer Portzki.

ON THE MANUFACTURE OF CHLORINE BY MEANS OF PERPETUALLY REGENERATED MANGANITE OF CALCIUM.*

BY MR. WALTER WELDON.

SINCE the last meeting of the British Association chlorine has begun to be manufactured extensively by a process which depends on the production and perpetual regeneration of a compound no mention of which, so far as I can find, as yet exists in chemical literature. As this process, besides thus producing and continually reproducing what I believe to be a new compound, reduces by fully 80 per cent. the principal item in the cost of the manufacture of chlorine, greatly increases the quantity of chlorine which can be practically obtained from a given quantity of hydrochloric acid, and, moreover, enables the manufacture of chlorine to be carried on without the production of any offensive residue, I have ventured to think that a very brief account of it might not be without interest to this Section.

What has hitherto been the ordinary process of manufacturing chlorine consists simply in digesting with hydrochloric acid ores containing peroxide of manganese. The reaction which takes place, besides liberating chlorine, produces chloride of manganese, which remains behind in solution after the chlorine has gone off, and has hitherto been usually thrown away. There have been proposed and tried a great number of processes for transforming this chloride into peroxide for use over again, but the only one of them which has met with the slightest measure of practical success, prior to that which is the subject of this paper, is the one which is known, from the name of its inventor, as Dunlop's process. Dunlop's process decomposes the chloride of manganese by heating its solution, under a pressure of from two to four atmospheres, with milk of carbonate of lime, and then, in the dry way, transforms the resulting carbonate of manganese into a mixture or compound of two equivalents of peroxide with one equivalent of protoxide, by subjecting it for 48 hours to the action of air at a temperature of about 600deg. Fah. The product of Dunlop's process is a sufficiently satisfactory one, containing about 72 per cent. of MnO^2; but the process requires a very formidable amount of apparatus, and in this and other ways is so costly that its use has never extended beyond a single firm of manufacturers.

Three years ago I began to endeavour to work out the idea of decomposing by either lime or magnesia the chloride of manganese in the residual liquors of the chlorine manufacture, and then blowing air through the resulting mixture of hydrated protoxide of manganese with solution of chloride of calcium or of chloride of magnesium, as the case might be. I took for granted that one-half of the protoxide of manganese so treated was the largest proportion of it that could thereby be converted into MnO^2—in other words, that one could obtain only sesquioxide by this method; but it was soon found that, when using lime to decompose the chloride of manganese, considerably more than half the protoxide operated upon was frequently converted into MnO^2. It was found eventually that more than half the protoxide was thus peroxidised only when more lime was used than simply the quantity necessary to decompose the chloride of manganese, and when what was treated with air was thus a mixture of protoxide of manganese and lime; and it was also found that in all such cases there was a definite relation between the quantity of lime associated with the protoxide of manganese and the quantity of the protoxide, in excess of half, which became peroxidised. This led to the discovery that whereas when protoxide of manganese by itself is treated with air in the wet way one-half is the maximum proportion of it which can thereby be converted into MnO^2, the association of a certain proportion of lime with the protoxide so treated will enable the whole of it to become converted into MnO^2. It is to this fact, together with that of the much greater rapidity with which protoxide of manganese can be peroxidised by treatment with air in the wet way when lime is present than when lime is not present, that the practical success of the new method of manufacturing chlorine is mainly due.

The action of lime in increasing the proportion of protoxide of manganese which can be peroxidised by treatment with air in the wet way evidently consists in the lime substituting itself for that part of the protoxide which, when protoxide of manganese not having any other basic substance associated with it is treated with air in the wet way, does not undergo peroxidation. It would seem that the production of MnO^2 in the wet way, by direct combination between hydrated MnO and atmospheric oxygen, absolutely requires the presence of a base with which the MnO^2 can combine as it forms. When protoxide of manganese, not having any other basic substance associated with it, is treated with air in the wet way, a part of the protoxide itself has to act as the required base; and this is the reason why, in that case, not more than half of the protoxide can become peroxidised, the other half being required to combine, as MnO, with the half which becomes converted into MnO^2. When, however, the protoxide of manganese which is treated with air in the wet way has lime associated with it, the MnO^2 which forms (or a part of it, according to the proportion of lime present) combines with CaO instead of with MnO, thus leaving free to undergo peroxidation that part of the MnO which, but for the presence of the CaO, this MnO^2 must have combined with, and which would thus have got locked up in a state in which it would have been incapable of being peroxidised, at least in the wet way and by air alone. Hence, the presence of enough lime to take the place of that half of the protoxide which, if no lime were present, would have to go into combination as base, and also to supply enough base for that half itself to combine with after undergoing peroxidation, will enable the whole of the MnO operated upon to be raised to the state of MnO^2. The minimum quantity of lime which is enough for this purpose is an equivalent for each equivalent of MnO operated upon, or the quantity necessary to supply an equivalent of lime to all the MnO^2 which can be produced by the peroxidation of all the MnO.

By treating with air, then, a mixture of protoxide of manganese and lime suspended either in water or in solution of chloride of calcium there is formed a compound containing MnO^2 and CaO in the proportion of an equivalent of one to an equivalent of the other. This compound may be regarded as sesquioxide of manganese, or Mn^2O^3, the MnO in which is replaced by CaO. I call it manganite of calcium, and believe it to be a new compound. Gorgeu, in 1862, described a compound which he called manganite of calcium; but his compound contained five equivalents of MnO^2 per equivalent of CaO, and the CaO in it was so feebly combined that it readily decomposed chloride of manganese. My compound contains only one equivalent of MnO^2 per equivalent of CaO, and has no action upon salts of manganese.

This compound has now been produced and reproduced to the extent of some hundreds of tons. The process of producing it and applying it to the manufacture of chlorine is conducted as follows:—The residual liquor which remains after a charge of manganite has reacted upon hydrochloric acid in any suitable still is run from the still into a well or other receptacle in which it is treated with carbonate of lime, to neutralize any free acid, and to decompose any sesquichloride of iron or sesquichloride of aluminium, which may be contained in it. The neutralized liquor is then pumped up into an elevated cistern, in which it is left at rest for a few hours in order that it may deposit certain solid matters which it now holds in suspension. The most abundant of these is usually sulphate of calcium, due to the somewhat considerable quantity of sulphuric acid which is nearly always contained in the hydrochloric acid produced in alkali works; but there are also small quantities of sesquioxide of iron, derived from the sesquichloride of iron in the hydrochloric acid, and sometimes partly from the lime used in the process, and larger or smaller quantities of alumina and silica, due to the lime. These impurities having deposited, the supernatant liquor, which is a mixed solution of chloride of manganese and chloride of calcium and is now quite clear and of a beautiful rose colour, is run off into another vessel, where there is added to it the quantity of lime necessary to decompose the chloride of manganese in it and nearly an equivalent more. A blast of air is then injected into the resulting mixture, and what was at first a perfectly white mud, all the manganese in which was in the state of MnO, soon becomes a very black mud, nearly all the manganese in which is in the state of MnO^2. This is then allowed to settle for about twelve hours, at the end of which time it has separated into a denser black mud and a supernatant clear solution of chloride of calcium. This solution of chloride of calcium having been drawn off, what remains is ready for use in the still. It is used as mud, without drying, being conveyed to the still by pipes and entering by a hydraulic lute. In the still it meets with hydrochloric acid, from which it liberates chlorine, at the same time reproducing exactly such a residual solution as was commenced with. With this solution the round of operations is recommenced; and so on, over and over again, continually. The samples I exhibit are portions of a charge of manganese which, at the works of Messrs. J. C. Gamble and Sons, of St. Helens—where this process has been worked out, by the liberal cooperation of Lieut.-Colonel Gamble, the proprietor of those works, and the invaluable assistance of Mr. Bramwell, the very able manager of them—has actually generated chlorine, from which bleaching-powder has been made, something like fifty successive times.

Hitherto, the principal item in the cost of chlorine has been that for native peroxide of manganese. Last year, in Great Britain, France, Belgium, and Germany together, there were produced about 120,000 tons of bleaching-powder, which cost, on an average, for native oxide of manganese, not much, if any, less than £5 per ton. My process substitutes for this cost for native oxide of manganese a cost for the regeneration of manganite of calcium not exceeding fifteen shillings per ton of bleaching-powder, being about ten shillings for lime, one shilling for steam, one shilling for wages, and two shillings for interest and wear and tear. Moreover, whereas hitherto, at least in this country and in all but an extremely few exceptional cases, the production of a ton of bleaching powder has required the acid from about 75cwt. of salt, my compound yields chlorine enough for a ton of bleaching-powder from the acid from less than 45cwt. of salt. This larger yield of chlorine is mainly due to the artificial manganite being so easily soluble that it can very readily be caused to neutralize from 95 to 99 per cent. of the acid employed, which is a very much larger proportion of it than can be neutralized when working with manganese ores. A third very important advantage of the new process over the old one consists in this, that whereas the immense quantities of acid which escape neutralization in the old process are usually—and have almost necessarily to be—sent into the rivers, as free acid, the only product of the new process which has to be thrown away is a perfectly neutral solution of chloride of calcium.

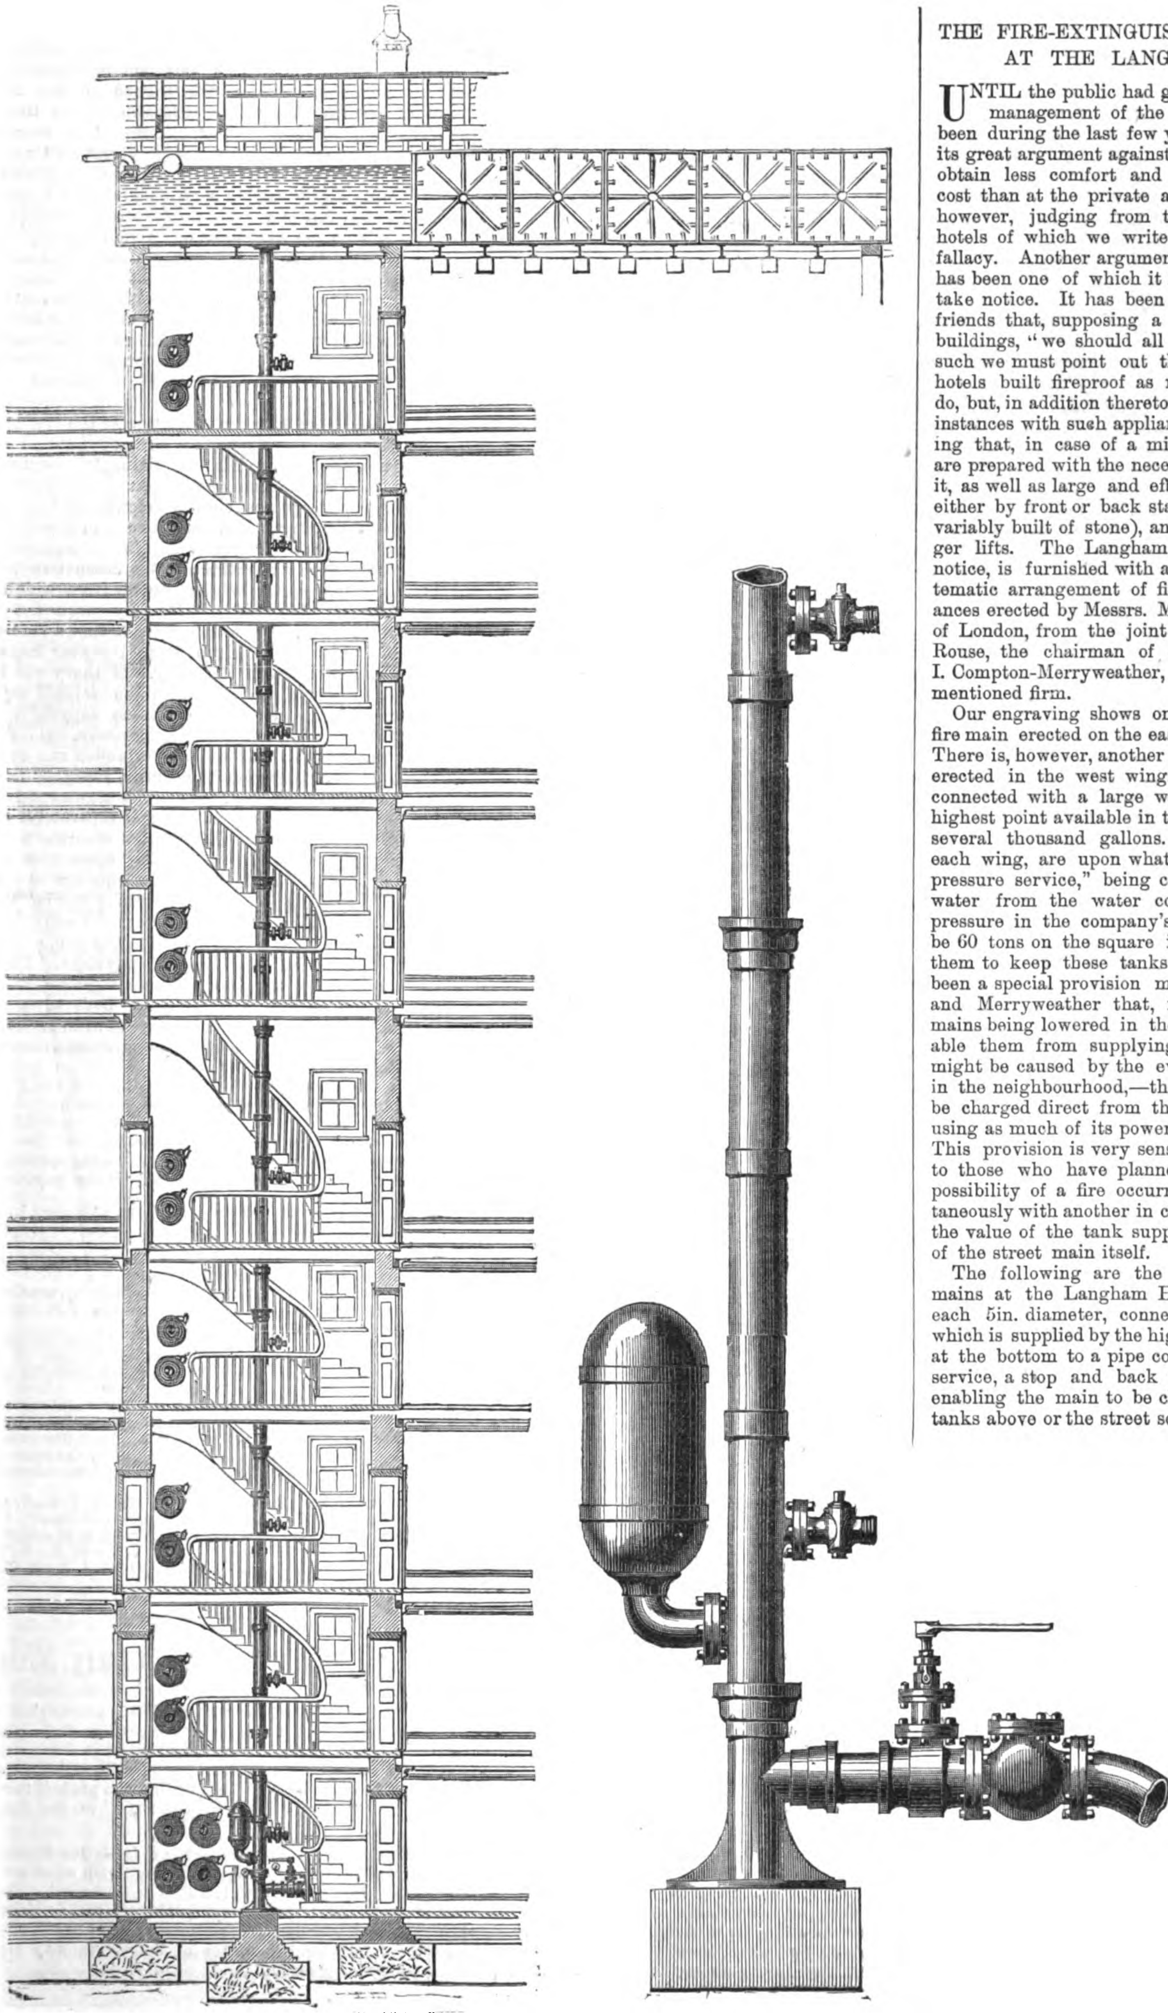
Seeing that manganite of calcium, or $CaMnO^3$, is only of the same value, precisely, in respect of the quantity of chlorine which it can liberate from a given quantity of acid, as sesquioxide, otherwise manganite of manganese, or $MnMnO^3$, it may be well to explain why it is preferable to produce and reproduce the former rather than the latter. The reasons for this are two. There is, firstly, the obvious reason that, when all the manganese is converted into MnO^2, twice as much work is done, per given bulk of material operated upon, as when only half the manganese is converted into MnO^2; and this, of course, would be a very important consideration, even if the transformation of chloride of manganese into manganite of calcium occupied the same time as its transformation into manganite of manganese. Really, however (and this is the second reason), the former operation, in which all the manganese is converted into MnO^2, does not occupy more than one-fifth of the time required for the latter operation, in which only half the manganese is converted into MnO^2; and hence, while the manufacture of chlorine by means of perpetually regenerated manganite of calcium effects the very considerable economy above stated, it is questionable whether chlorine could be manufactured by means of manganite of manganese, regenerated by the same method, more cheaply than by means of manganese ores.

The length of time which, when protoxide of manganese, by itself, is treated with air in the wet way, is required for its complete conversion into sesquioxide, is very remarkable, and the fact that hydrated protoxide of manganese is somewhat freely soluble, alike in water and in neutral solution of chloride of calcium, would seem to have something to do with it. It is a curious fact that the peroxidation of protoxide of manganese by treatment with air in the wet way is greatly retarded by the presence in the medium in which the protoxide is suspended of any proto-compound of manganese in the state of solution. Thus, in a solution of either chloride or any other protosalt of manganese, peroxidation will go on only extremely slowly; and solution of the protoxide itself, which will be present until the very end of the operation when protoxide alone is treated with air in the wet way, has the same retarding influence. On the other hand, when treating with air a mixture of protoxide of manganese and lime suspended in solution of chloride of calcium, there are formed solutions containing peroxide of manganese, in the presence of which peroxidation goes on with extreme rapidity. All these solutions are more or less deeply coloured, solution of the protoxide being without colour. I exhibit a sample of one of the coloured solutions, called by the workmen "the port-wine solution." The nature of these coloured solutions has not yet been fully investigated, but I believe them to consist of manganite of calcium dissolved in solution of oxychloride of calcium.

I may be permitted to mention, in conclusion, that while there is every prospect, from the rapidity with which the new process of manufacturing chlorine has been and is being adopted both in this country and on the continent, that within a period to be measured only by months nearly all the chlorine made in the world will be made by it, there is every likelihood that in nearly all cases a portion of the hydrochloric acid saved by it will be applied to the recovery of sulphur from alkali-waste. The chief reason why the recovery of sulphur from alkali-waste has been so little practised hitherto is that the manufacturers have considered it more profitable to use all their acid for the manufacture of bleaching-powder than to use any part of it for the recovery of sulphur; but the process which I have had the honour to describe will enable them to make even more bleaching-powder than they have made hitherto, and yet have enough acid left to permit of their applying to all their alkali-waste the only process for the recovery of sulphur therefrom which as yet has been found practically successful, and I am able to state that this application of a portion of the acid saved by my process will be extensively adopted.

* Read before the British Association—Section B.

FIRE-EXTINGUISHING APPLIANCES AT THE LANGHAM HOTEL.



THE FIRE-EXTINGUISHING APPLIANCES AT THE LANGHAM HOTEL.

UNTIL the public had gained confidence in the management of the large hotels that have been during the last few years opened in London, its great argument against them was that it would obtain less comfort and attention at a greater cost than at the private and smaller hotels; this, however, judging from the patronage that the hotels of which we write receive, has proved a fallacy. Another argument, none the less pointed, has been one of which it is now our pleasure to take notice. It has been urged by many of our friends that, supposing a fire to occur in such buildings, "we should all be roasted alive." To such we must point out that not only are these hotels built fireproof as much as it is possible to do, but, in addition thereto, they are fitted in most instances with such appliances for fire extinguishing that, in case of a mishap of any kind, they are prepared with the necessary apparatus to meet it, as well as large and efficient means of egress either by front or back staircases (the latter invariably built of stone), and the hydraulic passenger lifts. The Langham Hotel, which we now notice, is furnished with a most efficient and systematic arrangement of fire-extinguishing appliances erected by Messrs. Merryweather and Sons, of London, from the joint designs of Mr. J. L. Rouse, the chairman of the directors, and Mr. I. Compton-Merryweather, a member of the abovementioned firm.

Our engraving shows only an elevation of the fire main erected on the east wing of the building. There is, however, another fire main similar to this erected in the west wing. Each fire main is connected with a large water tank placed at the highest point available in the hotel, and containing several thousand gallons. These tanks, one to each wing, are upon what is termed the "high-pressure service," being constantly supplied with water from the water company's mains. The pressure in the company's mains must, however, be 60 tons on the square inch in order to enable them to keep these tanks supplied. There has been a special provision made by Messrs. Rouse and Merryweather that, in the event of these mains being lowered in their pressure so as to disable them from supplying the tanks—such as might be caused by the event of a fire occurring in the neighbourhood,—the hotel fire main shall be charged direct from the street main, thereby using as much of its power as may be available. This provision is very sensible, and praise is due to those who have planned it, for there is that possibility of a fire occurring in the hotel simultaneously with another in close proximity. Hence the value of the tank supply, and eventually that of the street main itself.

The following are the particulars of the fire mains at the Langham Hotel:—Two fire mains, each 5in. diameter, connected at top to a tank which is supplied by the high-pressure service, and at the bottom to a pipe connected with the same service, a stop and back valve intervening, thus enabling the main to be charged either from the tanks above or the street service direct, as occasion

may require. There being nine floors to the hotel, each has two firecocks, one in each wing. These firecocks have sufficient hose, which, when uncoiled, would reach and meet in the centre of the building, so that into any room upon any floor the hose could be carried to attack the fire in a few seconds. In addition to the fire mains in the east and west wings, Messrs. Merryweather and Sons have erected a fire main with the necessary cocks in the courtyard. These are connected both with the water company's high-pressure main and the fire tanks belonging to the hotel. A fire occurring in the basement would have but little success in materially damaging the building, owing to such a vast deluge of water as would be immediately and judiciously brought to bear upon it.

There are a few other appliances in this hotel which are worthy of notice as instantaneous applicants in the occurrence of a fire, and these are the portable fire pumps. Upon each floor of the hotel are placed three of these pumps charged with water. Hanging by them are two dozen leather buckets, in order to keep up the supply from taps which are connected with the various water supplies of the building. Each pump is placed in a conspicuous position and marked "fire pump," and we congratulate the management of so large a building on placing such useful machines at their patrons' hands. Every person in the building, from the conspicuousness of the fire pump, is aware of its presence, and, in the event of a fire, we feel assured that, from its simplicity, few would fail to fly to it whilst the attendant in charge of the more powerful extinguishing apparatus would be sent for to call it into requisition. In order to prove the simplicity of the fire-extinguishing arrangements at the Langham Hotel, we may mention that the whole is under the control of the engineer who has the charge of the general machinery; and, moreover, its simplicity is such that no person is required to constantly attend it. The Charing Cross and City Terminus Hotels have arrangements somewhat similar, and no one visiting such hotels—especially the Langham—can fail to see that every precaution is taken against fire ever attaining any ascendancy over such fire-extinguishing appliances as this hotel now has. We may here incidentally mention that the portable fire pump so extensively used at the above-mentioned hotels was the design of the late Mr. Wm. Baddeley, C.E., whose name often appeared in our columns in former years, and that there is scarcely a building of any importance but adopts this useful and inexpensive fire-extinguishing appliance. It is stated that seven-tenths or nearly three-fourths of the fires in London are extinguished by this means.

MANCHESTER STEAM USERS' ASSOCIATION.

THE ordinary monthly meeting of the Executive Committee of the above Association was held on Tuesday, July 27, Mr. William Fairbairn, President, in the chair, when Mr. L. E. Fletcher, chief engineer, presented his report, of which the following is an abstract:—During the past month 203 visits of inspection have been made, and 430 boilers examined, 253 externally, 8 internally, 3 in the flues, and 166 entirely, while in addition one has been tested by hydraulic pressure. In these boilers 71 defects have been discovered, 9 of them being dangerous. Furnaces out of shape, 2; fractures, 20; blistered plates, 13—3 dangerous; internal corrosion, 5; external ditto, 9—3 dangerous; internal grooving, 6; external ditto, 2; water gauges out of order, 3; pressure gauges ditto, 2; boilers without glass water gauges, 1; without safety valve, 1—dangerous; without pressure gauges, 1—dangerous; without feed back pressure valves, 4; cases of over pressure, 1; cases of deficiency of water, 1—dangerous.

On the present occasion Mr. Fletcher reports that six explosions have occurred during the past month, by which four persons have been killed and fourteen others injured. Not one of the explosions in question occurred to boilers under the inspection of this Association. The following is a statement of explosions, from June 26, 1859, to July 23, 1869, inclusive:—No. 25, July 5, plain cylindrical, egg-ended, externally fired, 3 injured; No. 26, July 6, particulars not yet fully ascertained, 1 injured; No. 27, July 9, "breeches," internally fired, 2 killed, 2 injured—total 4; No. 28, July 16, plain cylindrical, egg-ended, externally fired, 1 killed, 4 injured—total 5; No. 29, July 19, two-flue "Lancashire," internally fired, 4 injured; No. 30, July 22, plain cylindrical, egg-ended, externally fired, 1 killed. Total—4 killed, and 14 injured.

No. 25 explosion, by which three persons were injured, but fortunately no one killed, occurred at a colliery at about twelve o'clock noon on Monday, July 5. One of the Association's staff visited the scene of the catastrophe a few days after the explosion, but he was forbidden the opportunity of making an examination, although he stated he was delegated by this Association, and explained the importance of all these catastrophes being fully examined. Thus, though he had travelled upwards of 100 miles from Manchester to examine the exploded boiler, he was not allowed to see it, and was merely able to gather that the boiler was one of the plain cylindrical externally-fired class, and that it was rent in two main fragments, one of which was thrown to a considerable distance, while the roof of the engine house and another building were brought down.

WORKING MEN'S CLUBS AND THE CROSSNESS SEWER OUTFALL.

A VERY pleasant trip was afforded the members of the different clubs of London by the council of the Union on Saturday last. About 180 members met on board the "Black Prince" iron-boat at three o'clock, at the Temple and other piers down to Blackwall, for a visit to the outfall at Crossness, where they were received by Mr. F. E. Houghton, the engineer in charge, who conducted them over the works, first visiting the schoolroom and then the boiler and engine houses. The whole arrangements of machinery and apparatus employed for lifting the sewage from a very low channel into the reservoir were explained by Mr. E. Hall, F.S.A., who went with the boat and explained on the passage the nature of the works by the aid of diagrams, &c., which materially lightened his labours when they landed. The expression of surprise of some of the members at seeing from the upper floor of the engine house such ponderous masses of iron in a state of motion is something to be remembered. The workmen were distributed over the buildings, and the freedom with which they answered inquiries showed the great pleasure they felt in the visit. The cottages were also visited by some of the members, and the delight exhibited by the wives and children, all neat and trim, caused the day to be one of pleasure to them also.

On the return Mr. Hall desired to go over the Northern outfall at Barking, and preparations were made on shore for their landing, but an objection on the part of the captain, who feared the safety of the boat on the mud and a falling tide, caused a disappointment to be felt. This soon passed away on the matter being explained by Mr. Hall.

The boat then continued on her way to town, and congratulations were exchanged by the members to one another, and thanks voted to Mr. Hall for his exemplary conduct on this and former occasions. The members landed at their respective piers as the boat arrived. The next visit will be to Barking, where Mr. Hall has promised to attend.

WE are enabled to contradict in the most decided manner, says the "Army and Navy Gazette," the rumour which is afloat that Mrs. Childers and family are embarked on board the "Agincourt." The comforts of the First Lord of the Admiralty would, doubtless, not have been lessened by the presence of his "belongings" during the cruise he has undertaken with a view of increasing the efficiency of the officers and seamen of our two principal squadrons, but he is too desirous of inculcating discipline by showing that, if he forbids admirals and captains to take their wives to sea, he is himself ready to set a good example. Mr. Childers is accompanied by his son, who, we believe, will be the guest of Captain Burgoyne. We have reason to believe that the rules of the service will be thoroughly maintained by the First Lord, and there is no likelihood, while he is in power, of any relaxation occurring.

Legal Intelligence.

AN ALLEGED INFRINGEMENT OF DESIGN.

AN action, brought by Messrs. Minton and Co., of Stoke, against Messrs. Adams and Scriveners, of Longton, Staffordshire, was settled on the 27th ult., by the stipendiary magistrate, Mr. Davis. The supposed infringement consisted in placing upon cups and saucers a design corresponding in form or ornament to that registered by Messrs. Minton. In the course of an elaborate and lengthy judgment, Mr. Davis said no one would be inclined to withhold the attributes of extreme beauty and grace to the complainants' cups and saucers as works of art, or to deny the moral right of the original designer to a monopoly of production for a limited time, as a reward for the genius, skill, and labour involved in the production. There was a general close resemblance between the complainants' cups and saucers and those made by the defendants; and some of the details warranted the inference that there had been a servile imitation of the ivy leaf, for instance, the fibres, so characteristic of the ivy, represented on the complainants' manufacture, both on the cup and saucer, were found in corresponding places on the defendants' cup and saucer, emerging from the shamrock in a way certainly not seen in nature. The complainants sought to secure copyright in the distinctive pattern existing on the original saucer from which a photograph was taken, but they were not at liberty to prove by verbal evidence that a pattern existed upon it in a given form, however imperfectly represented in the copy. If there was no pattern distinctly represented in the certified copy, there could be no valid claim to copyright in respect to such pattern. He, therefore, held that the complainants had failed to establish any copyright in the pattern on the saucer, designed from the pattern on the cup. As to the argument that registration of the cup and saucer separately was not necessary, Mr. Davis held that separate registration was necessary where the same identical design was not applied to both cup and saucer, which was the case here. He was of opinion that the affixing the mark denoting a registered design to the saucer was not, as regarded the cup, a compliance with the conditions of copyright. There should have been, if not separate registration, at all events separate marking on both cups and saucers, and the saucer being defective in registration, and the cups in marks, the information could not be sustained.

TO CORRESPONDENTS.

THE MECHANICS' MAGAZINE is sent post-free to subscribers of £1 1s. 8d. yearly, or 10s. 10d. half-yearly payable in advance.

All literary communications should be addressed to the Editor of the MECHANICS' MAGAZINE. Letters relating to the advertising and publishing departments should be addressed to the publisher, Mr. R. Smiles, MECHANICS' MAGAZINE Office, 166 Fleet-street, London.

To insure insertion in the following number, advertisements should reach the office not later than 5 o'clock on Thursday evening.

We must absolutely decline attending to any communications unaccompanied by the name and address of the writer, not necessarily for insertion, but as a proof of good faith. ED. M. M.

Advertisements are inserted in the MECHANICS' MAGAZINE, at the rate of 6d. per line, or 5d. per line for 13 insertions, or 4d. per line for 26 insertions. Each line consists of about 10 words. Woodcuts are charged at the same rate as type. Special arrangements made for large advertisements.

Naval, Military, and Gunnery Items.

WE have heard through a reliable source that the challenge of Mr. Ashbury, the owner of the yacht "Cambria," has been accepted by Commodore Bennett, of the American yacht "Dauntless," and that the race is to be held during the present month of September, across the Atlantic, to the Sandy Hook Lighthouse.

THE Royal Commissioners on Irish Sea Fisheries commenced their inspection of the Irish coast on the 24th inst. at Waterford. The Admiralty have placed the Royal steam yacht "Vivid," Captain Sullivan commanding, at the service of the Commission, so that the means of inspection may be as perfect as possible.

At a banquet in the City Hall, Perth, Mr. W. E. Baxter, M.P., in replying to the toast of "The Navy," said,—We live in a period of changes, and one of the changes introduced by the present Government was the infusion of a little mercantile experience into the great spending departments of the State. They were convinced that considerable economies might be effected altogether apart from the question of reduction of force. Some of you, no doubt, are aware that the Navy Estimates for the present year were nearly a million less than they were for the year before. That saving represents about a penny sterling per pound income tax. Perhaps in February next you will find that something substantial yet remains to be done in the same direction. Don't, however, for a moment suppose that we are sacrificing efficiency. To keep scores of useless clerks, to fill warehouses with several years' supply of deteriorating stores, to retain at great cost hulks which never can be sent to sea, and which ought to be sold or distributed among the various ports as training vessels, to encumber the dockyards with old materials, and multiply offices for the sake of patronage, are not the best methods of promoting the efficiency of our fleet. The Board of Admiralty, while determined with a fearless hand to put an end to profuse expenditure and jobbery, are at the same time fully conscious that this great nation takes a pride in its navy, and is desirous that in no respect it should suffer from any fault of ours.

The return stating the wrecks, casualties, and collisions occurring to British ships abroad, reported to the Board of Trade in 1868, shows that 935 vessels, of 337,281 tons in the whole, were totally lost or partially damaged; 657 vessels belonging to the United Kingdom, and 278 belonging to British possessions. 680 vessels, of 252,484 tons, were totally lost, and 255, of 84,797 tons, partially damaged. 1,387 lives were lost, 1,187 from vessels belonging to the United Kingdom, and 200 from vessels belonging to British possessions; 12,183 lives were imperilled, but saved by remaining on board, or by assistance from shore or from other ships. Of the lives lost 159 were by wrecks, &c., on the coasts of Europe, 27 on the coasts of Asia, 18 Africa, 82 America, 80 Australia and New Zealand, 1,021 at sea. Of the 935 British vessels thus reported in 1868 as lost or damaged abroad, 229 were barks, 180 brigs, 96 brigantines, 16 cutters, 1 dandy, 9 ketches, 1 lugger, 126 ships, 84 steamships, 172 schooners, 2 sloops, 8 smacks, 9 snows, 1 yacht, 1 unknown. So far as regards casualties on the shores of India and the other British possessions abroad, a return is given which includes foreign as well as British ships, and shows that in the year 1868 237 British vessels, of 64,709 tons, were totally lost on those shores, and 22 British vessels, of 3,877 tons, were partially damaged; and 17 foreign vessels, of 5,452 tons, were totally lost, and 12, of 4,156 tons, were partially damaged. 277 lives were lost, 199 belonging to British vessels and 78 to foreign vessels. Thus the total loss of life reported in 1868 was 1,465, being 195 less than in the return for 1867, and 439 less than in the return for 1866. Of the lives lost 708 are due to vessels sailing and not heard of afterwards, 333 to vessels foundering, 309 to vessels stranding, 14 to vessels being burnt, 4 to exhaustion and exposure to cold, 22 to falling or being washed overboard, 61 to falling spars or wreck, falling from aloft, or collisions, 13 to boats or ships capsizing, 1 cause unknown; 1,301 lives lost were those of the crew, 164 of passengers. A return for the coast of New South Wales arrived too late to be included—it shows 28 casualties, and 71 lives lost. This annual return of the Board of Trade is to be regarded as still incomplete, many wrecks are not reported; but it is hoped that the return will gradually become more accurate, regular, and trustworthy.

Miscellanea.

A company has been formed for working coal mines in the communes of Bray-Maurage and Boussoit.

The number of visitors to the Patent Office Museum, South Kensington, for the week ending August 28, was 4,414. Total number since the opening of the Museum, free daily (May 12, 1858), 1,631,397.

Among the prizes offered by the St. Ann's Industrial Society, Jamaica, at the Third Exhibition, August 4, was one "For the field labourer who can produce the best certificate and who has worked no less than 180 days in the year ending June 30, 1869, £1."

The Suez Canal Company has just issued regulations for the navigation of the Suez Canal, to be opened on November 17 next. Art. 1 states that the navigation of the Suez Maritime Canal will be open to all ships without distinction of nationality, provided their draught of water does not exceed 7½ metres, the depth of the canal being 8 metres, equal to 26 English feet.

A geological congress is this week holding meetings at Catania, in Sicily. The proceedings will continue for four days, the fourth to be devoted to the ascent of Mount Etna, and a conference at the mouth of the crater. Catania has been often desolated by the eruptions of Mount Etna; one of these, of which we have an authentic record, took place 425 years before Christ.

The number of visitors to the South Kensington Museum during the week ending August 28, 1869, was—on Monday, Tuesday, Thursday, and Saturday (free), from 10 a.m. to 10 p.m., 17,481; Meyrick and other galleries, 17,387; on Wednesday and Friday (admission 6d.), from 10 a.m. till 6 p.m., 797; Meyrick and other galleries, 90; total, 35,705. Average of corresponding week in former years, 17,127. Total from opening of Museum, 8,753,613.

Within the last week the western province annual ploughing match has come off at the Cape of Good Hope on a farm named Wolvefontein, about 25 miles from Cape Town. The Parliament suspended its sittings for the occasion. The ploughing was admirably done. The ploughs of Ransomes and Sims, and Howard, both did their work well; but the best ploughing of the day was done by the single furrow plough of Ransomes and Sims, and the best ploughman in the field—in the colony perhaps—who has always carried off prizes before with a Ransomes and Sims' implement, was an unsuccessful competitor now because he was unable to bring his old implement and trained horses into the field.

The great city gas companies are preparing to remove their works from the midst of the crowded localities in which they are now placed, and carry them into the country. The existence of these works in their present position has long been a grave nuisance. The Imperial Company has secured a location in the fields near West Ham; the Chartered on the river bank, near the northern outfall of the great main-drainage system; and the City Company, at Blackfriars, will, it is believed, migrate, in the same direction. It is to be trusted that all the metropolitan gas companies will presently find it to their interest to remove entirely without the boundaries of the thickly-inhabited districts.—"Lancet."

The Board of Trade have awarded an aneroid barometer to Mr. Wm. H. Rowe, channel pilot of Falmouth, for his prompt and gallant conduct in saving life from drowning on the occasion of a pleasure boat being run down on July 28 by the steam ship "Dandy," off Plymouth. The "Dandy" was on an excursion trip to Plymouth, and on returning, when between Drake's Island and the Breakwater, ran into a pleasure boat, which was smashed to pieces. Mr. Rowe immediately jumped overboard, and by giving pieces of the boat to the persons in the water to support themselves by until boats came to their assistance, and by himself supporting a woman and two children who were clinging to her, was the means of rescuing the lives of all the persons who had been thrown into the sea.

On Wednesday week two miners, leaving Rosedale for Cleveland, one of the most lonely parts of the moor, found a gentleman lying head downwards in a ditch, and a bicycle lying upon him. From the marks on the road it would seem that the machine had become unmanageable in a deep rut, and had run over the bank, apparently capsizing with the rider as found. The gentleman was quite unconscious, and had evidently been lying out all night. He was carried to the nearest habitation, some miles distant, and medical aid was obtained. On Thursday it was stated that he had recovered consciousness, and that his main injury was a dislocated ankle. He is a Mr. M'Henry, from Glasgow, who has been "doing" Yorkshire on a bicycle. In the part of the moors where found he might have lain for a month without being discovered in ordinary times. He was subsequently removed to a railway station.

Patents for Inventions.

ABRIDGED SPECIFICATIONS OF PATENTS.

The Abridged Specifications of Patents given below are classified, according to the subject to which the respective inventions refer, in the following table. By the system of classification adopted, the numerical and chronological order of the specifications is preserved and combined with all the advantages of a division into classes. It should be understood that these abridgments are prepared exclusively for this Magazine from official copies supplied by the Government, and are, therefore, the property of the Proprietors of this Magazine. Other papers are hereby warned not to produce them without an acknowledgment:—

Boilers and Furnaces—334, 341, 345, 362, 370, 386, 401, 402

Buildings and Building Materials—314, 320, 330, 344, 356, 399

Chemistry and Photography—318, 336, 355, 368, 373, 375, 376, 385

Cultivation of the Soil, including agricultural implements and machines—339, 342, 369, 373, 377

Electrical Apparatus—306, 340, 390, 391

Fibrous Fabrics, including machinery for treating fibre pulp, paper, &c.—308, 310, 316, 363, 378, 387, 396, 404

Food and Beverages, including the apparatus for preparing food for men and animals—319, 324, 328, 329, 333, 358, 374, 381, 392

Furniture and Apparel, including household utensils, time-keepers, jewellery, musical instruments, &c.—311, 313, 322, 332, 335, 338, 343, 353, 366, 382, 383, 389, 395, 398, 403

General Machinery—307, 309, 315, 357, 360, 367, 377

Lighting, Heating, and Ventilating—403

Metals, including apparatus for their manufacture—305, 326, 337

Miscellaneous—304, 310, 317, 323, 327, 349, 350, 352, 364, 371, 388, 393, 397

Roads and Vehicles, including railway plant and carriages, saddlery, and harness, &c.—321, 325, 351, 359, 380, 394

Ships and Boats, including their fittings—None

Steam Engines—346, 379

Warfare—348, 354, 361

---

304 J. Whyte, Hoxton. *Tailor's scissors, &c.* Dated February 1, 1869.

The blades are constructed as follows:—The upper portion of the shoulder of each blade is formed with a curved projection, which is perforated for the pin or stud on which the blades work to be inserted. The lower portion of one blade has a pin or stud connected to it, the other has a slot in it for the last-named pin to work in, which slot is a segment of a circle struck from the upper pin on which the blades move. The bottom of the finger bow is of a flat form, and in a line with the back of the lower blade, thus enabling the shears to be closer to the table, and preventing, when cutting more than one thickness of cloth, any baggyness or sag in either fold.—Patent abandoned.

305 C. D. Abel, Southampton-buildings. *Casting ingots.* (A communication.) Dated February 1, 1869

A bottom for the mould to rest upon is constructed of cast iron alone, or of cast iron in combination with any suitable refractory material, the bottom being provided with runners or gates sunk below its surface. These runners are either simple grooves sunk into the metal or into the refractory material, or the grooves may be lined with prepared fireclay or firebrick, or any other suitable heat-resisting material. In the centre of this bottom a removable disc of cast iron or firebrick or any suitable material is placed to take the stream of metal as it falls into the centre or "sprue" mould as often as may be necessary. This disc may be replaced, and thus the wear of the main bottom be prevented.—Patent completed.

306 T. G. Daw, Regent-street. *Stereotype matrices.* Dated February 1, 1869.

This consists, chiefly, in the peculiar arrangement of a series of levers, each of which carries a type, and is provided with a finger key whereby it can be depressed independently of the others. These levers are arranged over the table, on which is placed the plastic bed wherein the mould or matrix is to be produced. It is necessary that the type levers should be so arranged together, in relation to a certain point in the plane of the matrix, that each type of the series when depressed will be brought to this point, and the patentee prefers to arrange them in a circle around the said point, all of the finger keys being then in a convenient position to be reached by the operator.—Patent abandoned.

307 J. A. Limbert, Gravesend. *Moving heavy bodies* Dated February 1, 1869.

The inventor forms the fixed wheel with a hole in its centre to fit a concentric portion of the axis or eccentric carrying the movable wheel so as to maintain the fixed wheel in a proper central position with respect to the other gearing, and he forms such fixed wheel with lugs, ears, or projections to fit the frame of the block, which he casts or otherwise forms in one piece. The ears, lugs, or projections on the fixed wheel may be formed so as to clip both sides of suitable parts of the frame, or so that some may clip on one side of some parts with both sides of other parts, or on one side of some parts and others on the opposite side of other parts of the frame.—Patent completed.

308 A. V. Newton, Chancery-lane. *Condensing slivers.* (A communication.) Dated February 1, 1869.

The working surface of the doffer cylinder, instead of being (as is ordinarily the case) cut up into bands to reduce the sliver into ribbons, is formed with a continuous card surface, and the sliver, as it is taken off by the doffer comb, is taken up by endless bands or other equivalents, whose office is to divide up the sliver into ribbons and deliver the ribbons to condensing rollers, which will give to the ribbons a proper amount of consistency to allow of their being wound into a roll ready for transmission to the roving frame. The width of the bands will depend on the width of the ribbons of sliver required to be formed for conversion into rovings. The bands may be brought near enough to the doffer to take up the sliver directly therefrom, or a take-up roller may be interposed between them to deliver the sliver into the bite of the bands.—Patent completed.

309 J. A. Andre Fontaine, Paris. *Hydrostatic hoist* Dated February 1, 1869.

This consists, first, of a tube almost entirely filled with water, called the "hydrostatic tube," in which is plunged (either free or otherwise) a cylinder, which, alternately filled with air or with water, produces by virtue of the hydrostatic principle above named, the ascent and descent of the load platform, with which it is connected by means of a traction rope, which passes in different directions over a system of pulleys. This cylinder is called the "ascender." Second, of a framework called the lift frame, in which the load platform rises and descends, guided by wheels on vertical rails placed on the columns forming the framework. Third, of a system of mechanical arrangements which effect the emptying of the water from the ascender in the hydrostatic tube, and at the same time the filling of the same with air.—Patent abandoned.

310 R. Caunce, Mansfield, M. G. Bradley, and B. Bradley, Nottingham. *Yarn twisting machines.* Dated February 2, 1869.

A tube of metal or other suitable substance is firmly fixed in the top spindle rail of the machine (which rail is a fixed one), and at such a length as to pass through a movable rail called the copping rail, and reaching nearly

to the top of the blade of the spindle, which passes through the tube. This tube is of sufficient strength to form a steady bearing or bolster for the spindle, and also to serve as an axle for the bobbin to revolve upon.—Patent abandoned.

311 C. HOULT, Wolverhampton. *Fireplace screens.* Dated February 2, 1869.

This consists in making, by the use of sheets of glass, transparent, semitransparent, or opaque screens, some of which are highly ornamented on the surface by cutting or being pressed or moulded or silvered at the back to serve as mirrors, or in any other convenient method. It is preferred, however, to use one or more sheets of plain glass, and to apply to the surface intended to be the back thereof any desired ornamental design in gold, silver, or colours, or imitation jewels, or any combination thereof, or to place behind such sheet or sheets of glass any painting in oil, or water, or otherwise, (or photograph plain or coloured), or otherwise glass into a frame of metal or other material, by preference stamped out of sheet metal iron or tinned iron, or they may be cast in copper, brass, or steel, or other material. Some of the metal frames are japanned, painted, or varnished, in such a way that they are themselves of an ornamental character.—Patent completed.

313 J. PROUD, Carlisle. *Basket cars.* Dated February 2 1869.

This consists, first, in fixing the uprights (which may be of iron, wood, or other material) of the basket or wicker work into a bar of wood which is fastened to the frame of the car. By this means, the wicker work is raised a little above the floor or bottom of the car, and prevented from being rotted by any water which may lodge therein.—Patent abandoned.

314 N. VOICE, Handcross, Sussex. *Water-closet machines.* Dated February 2, 1869.

The inventor takes (say) a tube of india-rubber, and encloses it at one part of its length in an outer tube of metal or other suitable material. This outer tube is provided with a boss or enlargement, in which a lever, screw, or other appliance for exerting pressure on the rubber tube is fitted. If the appliance for exerting pressure be a weighted lever, it compresses the portion of the rubber tube which is within the boss, and thereby prevents passage of water through it, but when the lever is raised by any ordinary means, the rubber tube is free to resume its natural form, and to permit the fluid to flow through it. —Patent abandoned.

315 D. JOY, Saltburn. *Oil machines.* Dated February 2, 1869.

This consists, first, in causing the faces between which the oil, seed, or other substance to be pressed lies to act as strainers, by constructing them of a number of ribs or plates, in the form of a grid or grate of any suitable figure or of cubes or polygons placed together, so that through the interstices between such ribs, cubes, or polygons, the oil or other liquid to be extracted may escape while the solid matter is reclaimed, or the inventor uses plates with holes cast, drilled, or punched therethrough, so as to permit of the drainage above named.—Patent completed.

316 S. BROOKE, Brighouse. *Condensed carding engines.* Dated February 2, 1869.

This consists in the application of a series of knives or blades fixed in front of the doffer cylinder at suitable distances apart, and so as to enter slightly into or between the card teeth, also in the employment of a series of combs or "doffing plates." Or one such plate is formed by spaces at intervals, so as to work or reciprocate in betwixt the knives or blades for stripping the film of wool or fibre from the doffer in strips or ribbons. Also a grooved roller placed in front of the knives (which enters therein) to receive and carry the strips of wool or fibre forward therefrom to a pair of grooved rollers, which conduct the same to the ordinary rubbers of the condensing machine. One of these rollers is formed with concave grooves, and the other with convex, or so as to fit in the grooves of the other roller.—Patent abandoned.

317 A. E. HARRIS, Mile End-road. *Artificial teeth.* Dated February 2, 1869.

This consists in cutting away the parts of the plates which correspond to the palate or the bottom of the lower jaw, where the tongue would naturally rest in the act of tasting, and by inserting in the space so cut away a piece of perforated platinum of exactly the same shape as the piece cut away, and consequently filling up its place entirely.—Patent completed.

318 W. I. PALMER, Reading. *Evaporating and calcining.* Dated February 2, 1869.

The inventor employs, first, a shallow pan or hearth, by preference with a concave surface and heated by furnaces or flues. To this pan or hearth he attaches an agitator so fixed and driven as to perpetually rake, stir, or agitate the surface of the thickened liquor by which the rapid evaporation of the remaining aqueous particles is greatly promoted.—Patent completed.

319 W. A. SMITH, Manchester. *Preserving meat.* Dated February 2, 1869.

The inventor uses any ordinary refrigerating apparatus such as the "compressed air," the "sulphuric acid," "the ammonia," or other machines, the construction and use of all of which are well known, but he prefers the first-mentioned, known as A. E. Kirk's machine. When using this machine the inventor takes a tank of any convenient size capable of being covered, and places therein a number of cases made of tin, tinned or galvanized iron, copper, or any such metallic substance, and having placed the meat or substance to be preserved therein, fills it up with water. After this the brine from the refrigerating apparatus is caused to circulate round the cases, by which a solid frozen mass is obtained enclosed in cases which may be packed in wooden boxes for transport, or placed one upon another in a railway van with felt, sawdust, or other non-conducting material between them if found necessary.—Patent completed.

320 J. BIRD, Kingswinford. *Brick kilns.* Dated February 2, 1869.

The inventor forms in the outer chimney stack or stacks at a suitable height, a firegrate or firegrates furnished with a damper or door for closing up the flue opening or firegrate when required, a damper or dampers being also provided in a short flue or flues upon the top of the kiln. From the firegrate in the base of the stack the ordinary air culvert or passage traverses underneath the floor of the kiln to a central open mouth or vertical flue into the drying chamber, other traversing or radiating flues being formed beneath the floor of the kiln and communicating with the main flue.—Patent completed.

321 W. E. NEWTON, Chancery-lane. *Permanent way.* (A communication). Dated February 2, 1869.

The lower portion or base of the rail is provided with a rib bevelled on the outer side of its upper edge. It has a groove running its entire length, and is perforated with round or square slots. The upper portion or head has a rib also bevelled upon one edge and a groove. Through the rib are slots elongated horizontally, with the lower surface made flat to correspond with the flat side of a key; these slots are also of greater diameter vertically than the slots in the base. The grooves in both head and base have a pitch exactly corresponding to the bevelled edges of the ribs.—Patent completed.

322 H. BATE, Hackney-road. *New top.* Dated February 2, 1869.

This consists in enclosing within the body of the top a fan wheel or flier horizontally mounted upon a tube or barrel so as to revolve upon a fixed vertical spindle or peg upon which the same is spun, in connection with which musical combs or wires secured internally to the sides of the top, are employed for sounding the notes or chords through the medium of striking pins or points formed upon the revolving barrel in like manner to the action of the musical box.—Patent abandoned.

323 Captain W. BRABAZON, Malahide, Ireland. *Oyster dredge chain.* Dated February 2, 1869.

The links of this dredge are runners like those of a snow sleigh. They are turned up at the ends and connected by an iron ring or link, which rests on them and presents a smooth under surface which carries it along the bottom of the sea, passing over the spat and brood of oysters, mussel, &c., without injury to them.—Patent abandoned.

324 V. BAKER, Aldershot. *Vessels for hot liquids.* Dated February 3, 1869.

The inventor constructs the vessels with a double casing, having a space between the inner and outer casings which may contain air, or may be filled with imperfectly conducting material such as wool, hair, feathers, or the like. When the vessels have covers or lids, he makes them also double, with a space containing air or imperfectly conducting material. When the vessels have a spout or tube he makes it good to the inner casing, passing it through the space between the casings and the outer casing so that it communicates with the inside of the vessel only.—Patent completed.

325 J. SLATER, Fitzroy Works, Euston-road. *Railway carriages.* Dated February 3, 1869.

In addition to the two sets of buffers at present in use, the inventor places two or more single or sets of buffers on each railway carriage, truck, van, waggon, or car, on any part thereof, but, in preference, on the top, and placed so as to act in a manner similar to the ordinary buffers, and to meet at the same time.—Patent completed.

326 J. G. WILLANS, St. Stephen's-crescent, Paddington. *Iron and steel.* Dated February 3, 1869.

This consists chiefly in applying one or more jets of steam, either superheated or intermittently, in iron blast furnaces, not at the tuyeres, but by preference in that part in which the ores and fuel are at a red heat, but not fused in order to carry off sulphur therefrom.—Patent completed.

327 J. MACINTOSH, North Bank, Regent's Park. *Ornamenting surfaces.* Dated February 3, 1869.

This consists in using a combination of paraffin or stearic acid, india-rubber, and collodion mixed with metallic powders or gold or silver leaf, for the ornamentation of surfaces whereby they are rendered waterproof, and not liable to tarnish or oxidation. In some cases the compound of india-rubber and paraffin or stearic acid is used as a ground, and the metallic powder or leaf spread or laid thereon, and the whole coated with a clear solution of varnish to prevent oxidation.—Patent completed.

328 J. H. TYRRELL, Hadleigh, Rochford. *Liquid register and drawer off.* Dated February 3, 1869.

This consists of improved mechanical arrangements connected with a tap or cock, whereby the quantity of liquid required to be drawn off is first measured into a closed vessel from the vessel that contains it in bulk, and the plug of the tap or cock is so constructed that when it is opened to discharge the contents of the aforesaid closed vessel containing the precise quantity to be drawn off, the tap shuts off the communication between the closed vessel and the vessel from which it is supplied. In connection with the plug is a pin or stud, which as the cock is shut operates upon a train of wheels for indicating by dials, and a hand on each pointing to figures on the dials, which indicate the gross number of measures of quantity of the liquid drawn off, the dials being visible through a piece of glass fixed in front of them.—Patent abandoned.

329 A. S. STOCKER and A. R. STOCKER, Horsleydown. *Infants' feeding bottles.* Dated February 3, 1869.

This consists, first, in adding to screwed caps or stoppers to be applied to and employed with infants' feeding bottles, necks or collars for the purpose of holding the india-rubber feeding bottle, sucking-tube, and its appendages as well as for holding an india-rubber washer intended to act as a valve or passage way round the edge of the centre orifice and to admit the air between the edges of the neck or collar and the edge or edges of the hole made through the centre of the india-rubber or other ring which is held by this neck or collar, when suction takes place into the vessel.—Patent completed.

330 C. D. ABEL, Southampton-buildings. *Artificial stone.* (A communication.) Dated February 3, 1869.

The principal components of this hydraulic cement are lime, silica, and alumina, the two latter being by preference extracted from refractory clays. In order to bring about the formation of the double silicate of alumina and lime, sulphuric and boracic acid are added in small quantities to the compound.—Patent completed.

332 C. E. BROOMAN, 166, Fleet-street. *Corsets and stays.* (A communication.) Dated February 7, 1869.

This consists in employing in corsets or stays, instead of the ordinary full body of stuff, an openwork of tapes or ribbons laced or crossed over each other, and over or at the back of the covering of the bones, stays, or uprights, which form the frame of the corset, such ribbons or tapes being crossed vertically and horizontally, or diagonally, as required.—Patent completed.

333 W. LISTER, Chicago. *Syrup filter.* Dated February 3, 1869.

The inventor employs charcoal, dust, or charcoal in a fine state of division instead of charcoal in a granular condition as hitherto, and forces the solutions or syrups through the charcoal dust or powder by pressure produced by a circulating pump or by the direct application of steam or other fluid to the surface of the said solutions or syrups. The filtering vessel, which may be of any desired outline (although he prefers a cylindrical vessel placed in a vertical position) is fitted with a false bottom, whereon a blanket or other piece of woven fabric supporting or carrying the fine charcoal is placed.—Patent abandoned.

334 W. MADDICK, Manchester. *Boilers.* Dated February 3, 1869.

This consists in coating or covering the exteriors of the tubes with lead either in the state of sheet metal or by dipping them into lead in a molten state, which operations are for the purpose of preventing the tubes from incrustation and corrosion.—Patent completed.

335 R. R. FROHOCK, Boston. *Last machine.* Dated February 3, 1869.

This consists, first, in placing the model last upon mandrels parallel to the mandrels upon which the block revolves, the mandrels running in fixed housings and being connected by reversible gear so that they may be made to revolve in the same or in opposite directions; second, in hanging the guides upon one set of swinging frames and the cutter wheels upon another set, one set of swinging frames being connected by a peculiar device to a second bar to which the other set of swinging frames is connected, the distance from the point of contact of the guide to the axis of oscillation of the guide frame being equal to the distance of the cutting point of the cutter wheels from the axis of oscillation of the cutter wheel frames.—Patent completed.

336 J. R. JOHNSON, Haymarket. *Photographic pictures.* Dated February 3, 1869.

This consists of a new mode of treating the pigment to be used in the production of these pictures, which is required for this purpose to be in the finest possible state of division, and has hitherto only been successively used in a moist condition fresh from the mill or grinder. If kept for some time after grinding aggregation takes place among the particles of the pigment, and the results are then no longer of the same degree of perfection. A moist pigment, unless specially treated, is also of unequal density and cannot be used conveniently to obtain definite shades of colour, equal portions of such pigment giving unequal depth of colour. The inventor obviates this inconvenience by mixing thoroughly by mechanical means the finely ground pigments, black, red, or other colours, with gelatine and sugar, these being in much smaller proportions than that which is required for the production of the sensitive compound, say four parts of the gelatine and two of sugar to one part of the dry colour, but these proportions may be greatly varied, and he pours the mixture upon a slab or surface where it is allowed to set and dry. The sheet of prepared pigments is then cut up into leaves or cakes. He prepares in the same manner transparent or colourless sheets or cakes of the gelatine or similar substance mixed with its proper quantity of sugar or like material, and he forms the tissue of variable tint by dissolving variable quantities of these, that is of the prepared gelatinized pigment and of the transparent or colourless compound, and spreading the tissue compound so prepared upon paper, as is well understood, the result being definite, and the pigment being in its most perfect state of division. By pigment the inventor means not only those pigments used in oil or water colour painting, but those used for painting upon glass, enamel, and ceramic surfaces.—Patent completed.

337 L. WRAY, Ramsgate. *Wrought-iron carboniser.* Dated February 3, 1869.

The inventor heats the articles in a reheating furnace, and while thus heated he plunges them into a bath of molten cast iron. The length of time they are to remain in the molten cast-iron bath will depend upon the nature of the article to be operated upon and the effect it is desired to produce. For instance, railway bars or rails will require a much longer time than articles not subject to such rough and severe wear and tear.—Patent abandoned.

338 A. V. NEWTON, Chancery-lane. *Sewing machinery.* (A communication). Dated February 3, 1869.

This relates to a novel arrangement of machinery which by the use of two threads will produce a whip stitch suitable for sewing the seams and backs of gloves. The material to be sewn is put in a travelling spring cramp, set at right angles to a horizontally working needle, or it may be that the material is held between rotating cylinders, which will form the cramp. In either case the upper edge of the cramp or holder is notched to receive and guide the needle. The upper edge of the crank is level with the needle, so that the latter in working to and fro will advance into one of the notches on the upper edges of the cramp, and which give the latter a saw-like appearance.—Patent abandoned.

339 J. HOWARD, Bedford. *Turn wrest ploughs.* Dated February 3, 1869.

The plough is constructed as is usual with two bodies, the one right handed and the other left handed, which are fixed on opposite sides of a common beam, the heads of their respective frames being secured to the beam by screw bolts, which pass through both heads and through the beam. The construction of the beam is somewhat peculiar. It is formed of two bars trussed or strutted at the middle, and for the greater portion of their length and terminating at both ends in solid portions. The foremost end of the beam carries the head and brake of the plough, and the rear end of the beam carries the handles. The portion to which the handles are fitted is made cylindrical to allow of the beam turning on its axis without the handles in order to invert the plough bodies at pleasure, and it is provided with catches or teeth, which fit into notches formed on the sliding socket or collar that carries the handle, and thus serve to lock the handles to the beam while the plough is in use. The plough carriage is fitted with a pair of running wheels and capable of adjustment (through the action of a vertical screw) to any height to suit the work in hand.—Patent completed.

340 H. and J. BRYCESON and T. H. MORTEN, Stanhope-street, N.W. *Electric organs.* Dated February 4, 1869.

The first improvement relates to an arrangement for maintaining for any required length of time the current of electricity round the electro-magnets of the drawstop apparatus, however great the rapidity with which the knobs are moved by the performer, and for actuating on the inflation of the main bellows of the organ the positive

or negative electro-magnet of each drawstop apparatus, so as to insure a correspondence between the position of each slider and the position of the knob at the keyboard to which it belongs. The second improvement relates to an adaptation of hydraulic cylinders and a column of water for opening the swell louvres, whereby a great saving of friction is effected when the motion is required to be transmitted to a distance or in an indirect line. The third improvement relates to an adaptation of hydraulic cylinders and a pressure of water for working the combination movements, so that they can be commanded by the performer without offering the usual great resistance.—Patent completed.

341 T. PARKINSON, Liverpool. *Furnace "air doors."* Dated February 4, 1869.

This consists in casting, forming, or attaching on or to the door a tank or vessel to contain water or other liquid, and in placing within the tank a so-called aerometer, which aerometer gives motion to the regulating shutter or valve (the latter of novel construction) acting in or over air entrance apertures formed in the door.—Patent abandoned.

342 J. J. BAGSHAWE, Sheffield, and W. F. BATHO, Birmingham. *Semolina and flour machinery.* Dated February 4, 1869.

The inventors construct, first, rolls of a corrugated or wavy longitudinal section, so that at different points in their axial line they will be of different diameters, the corrugated or wavy surface of the rolls being grooved or toothed in any convenient manner for acting upon the grain or semolina. Secondly, they use grooved or fluted rolls in pairs of unequal diameter driven at equal angular velocities, thus causing a different surface velocity and more effectually operating upon the grain and semolina. —Patent abandoned.

343 E. D'ARTOIS, Charlotte-street, Fitzroy-square. *Inkstands.* Dated February 4, 1869.

The inventor preferably gives to the inkstand the form of a gun, although any other shape may be used. The inside of the gun is a glass tube, which is closed at one end in a rather conical form at half an inch over that end, and perpendicular to it the glass is pulled in so as to form a cone filling very nearly all the diameter of the tube; the bottom of that cone is terminated with a small hole giving communication inside the tube. The other end of the tube is quite open in its diameter to receive the ink, and is after that corked or sealed very tight. This being done the tube is surrounded with a plastic stuff, wood, or any kind of metal or stuff which has received before the form of a gun.—Patent abandoned.

344 T. PANKHURST, Chatham. *Gulley traps.* Dated February 4, 1869.

This consists in furnishing sewer gratings or gulleys with an under or catch receptacle having a passage way or hole in it furnished with a movable pan, flap, or door, pressing against such passage way or hole attached to a lever bearing an equipoise. The pan, flap, or door will therefore be self-acting when any material or fluid falls on it from or through the catch receptacle by reason of the weight of such material or fluid, and after allowing it to pass will then close and so trap the hole or passage way in the bottom of the catch receptacle, and thus prevent the escape of effluvia.—Patent abandoned.

345 E. LORD, Todmorden. *Furnaces for steam boilers.* Dated February 4, 1869.

To the under side of each grate bar is cast a clip or fork, which rests upon an eccentric, and there are as many eccentrics as there are grate bars in the furnace, the eccentrics being fixed on a shaft, so that the high part of one is near the low part of the adjoining one; consequently as the eccentrics revolve the grate bars are raised and lowered and caused to advance and retreat alternately. The inner ends of the grate bars pass partly under the bridge, and are supported on a cross rail or other equivalent.—Patent abandoned.

346 P. JENSEN, Chiswell-street, E.C. *Propelling ships.* (A communication.) Dated February 4, 1869.

For utilising the pitching of the vessel its stem is provided with a false stem some distance in advance of the other strongly joined to the keel at the bottom and to the stem at the top, and preferably made in one piece with them, forming together a frame resembling the sternpost of a screw steamer. Bracing rods unite the false stem with the sides of the ship if required. In the frame there is an upright pillar fastened at top and bottom. Somewhat below the water level this pillar passes through the centre line between two flaps or systems of flaps, jointed together by a hinge joint running fore and aft, fastened to or pivoting in the stem and false stem. At or near the middle of the outer edge of each of these flaps, starboard and larboard, a rod or system of rods is jointed, running up to and jointed with a sliding sleeve or collar working freely on the vertical pillar.—Patent abandoned.

348 J. VAVASSEUR, Gravel-lane, S. *Working ordnance.* Dated February 4, 1869.

The inventor mounts on the gun carriage an axle carrying a toothed pinion or pinions gearing into a rack or racks fixed to the bed or slide upon which the carriage recoils, such racks being by preference formed by cutting slots in metal plates fixed to the slide or bed. Near each end of this axle is a toothed wheel, which during the recoil of the gun is loose upon the axle, but which when the gun is to be run forward or moved is made fast therewith by a clutch. With the toothed wheel gears a pinion, which is actuated by a crank handle, so that when the toothed wheel is fast on its axle the gun may be run forward by turning this crank handle. At the front end of the carriage are two rollers so arranged that when the carriage is down on the slide ready for firing these rollers are just clear of the slide and take no part of the weight. —Patent abandoned.

349 E. MOREWOOD, Briton Ferry. *Tin and terne plates.* Dated February 4, 1869.

In coating with tin or terne metal the inventor causes the plates which are to be coated to pass through a flux of such as chloride of zinc or other soluble metallic salt heretofore employed, so as to give them a tendency to rust if it remains on their surface after they have obtained their coating. This flux causes the surface of the iron to take a coating with melted metal very readily.—Patent abandoned.

350 G. BRAY, Deptford. *Slip hook.* Dated February 4, 1869.

This consists in hinging, swivelling, or jointing the loop of the hook so that one half of it turns back sideways. One means of forming this hinge or joint is to use a hinge pin having its axis in the same plane with the hook, and the effect of dividing and hinging the hook is that in case of accident when a considerable strain is put on the trace or other attachment, the upper or under half of the hook as the case may be is free to turn on the hinge pin without any increased strain on either part or on the point of the hook.—Patent abandoned.

351 W. E. NEWTON, Chancery-lane. *Railways for elevations.* (A communication.) Dated February 4, 1869.

This consists, first, in a novel construction of the endless rope or chain, which is provided with a series of knots, protuberances, or bosses arranged at regular distances apart to give to it a pitched character for gear with an indented wheel carried by the carriage or vehicle. Second, the invention consists in the combination of a brake and indented wheels carried by the carriage so arranged and operated that while the indented wheel with which the endless rope gears is free to rotate when the brake is off (or during the early application of the brake), and until the extreme or gripping pressure is applied by the rim of the endless rope over and in gear with it, a positive as contra-distinguished from a frictional hold of the indented wheel on the rope is established by or through the operation of the brake so as to effect the traction of the engine.—Patent completed.

352 H. JONES, Portland-place. *Tuning forks.* Dated February 4, 1869.

The inventor uses a sheath or case, into which he fits a tuning fork so that the forked ends remain free to vibrate therein, and near such ends openings can be made in the above-named case or sheath, a striker being fitted therein, usually radiated with three, four, or more radii, so that two remain within and one, two, or more protrude beyond the case or sheath, which striker, upon being pressed by the thumb or finger, presses the end of the tuning fork, which, when suddenly relieved, emits the musical sound.—Patent completed.

353 G. and E. ASHWORTH, Manchester. *Paper fasteners.* Dated February 5, 1869.

This consists generally in effecting all the operations requisite to make the fasteners from a continuous sheet, riband, or strip of metal in one apparatus, all the operations being self-acting. That is to say, when the apparatus is driven by power, and is supplied with a continuous riband or strip of metal, it will continue for some time to form fasteners therefrom without the intervention of the hand, the fasteners requiring only to be lacquered, tinned, silvered, or otherwise similarly finished in order to be fit for sale. The invention also consists in certain methods of supplying material to the apparatus or to modifications thereof, and also in the general construction and operation of the apparatus.—Patent abandoned.

354 J. JOBSON, Derby. *Explosive projectiles.* Dated February 5, 1869.

The object of these improvements is to admit of the head or fore end or part of the projectile being split or broken up into a number of definite forms or parts. Also by the form of a portion of this head or end to facilitate the separation and distribution of parts composing the cylindrical or parallel portion or body of the projectile. Another object of the improvements is to ensure the fracture or division of the parts of the projectile into definite portions or sections by forming such parts with surfaces inclining in opposite and other directions, or partly inclined and partly in a frame at right angles to the axis of the projectile, or parallel to such right angle, the object being to form the rings so that the parts of them, by being of varying thickness, may be better adapted for the portions of one ring in their action upon those of another on the explosion of the contained explosive matter to effect fracture thereof into definite forms.—Patent completed.

355 F. BRABY, Camberwell. *Utilising sulphate of iron.* Dated February 5, 1869.

This consists in bringing the ammoniacal liquor or vapour obtained by distillation from any solution or liquid containing ammonia, such as the waste liquor from gasworks, into contact with the crude solution of sulphate of iron.—Patent completed.

356 W. BLUNDELL, Upper Thames-street. *Chimney guards.* Dated February 5, 1869.

The guard or casing, which is to be placed on the chimney top in the usual manner, is made rectangular in cross section, and covered at its top by a suitable cap. The sides at their upper parts are formed with openings, the combined total area of the openings at each side of the guard or casing being equal to the cross sectional area of the guard or casing itself. Each opening is provided with a flap or louvre piece working horizontally on pivots or centres in such manner that the upper part of the flap or louvre piece, when it is closed, shall slightly overlap the inner edge of the upper part of its opening, while the lower part of the flap or louvre-piece in the same position, in like manner overlaps the outer part of the lower edge of the opening. Each flap or louvre-piece is so balanced by a weight (or by other suitable means) as to stand at an angle when at rest, thus leaving its opening clear for the escape of smoke or vitiated air, but so, nevertheless, that the slightest current of air from without shall have the effect of causing it to close its opening.—Patent completed.

357 J. PAGE, Glasgow. *Pipe joints.* Dated February 5, 1869.

The external joint service of the spigot is made either cylindrical or slightly conical, and the internal joint surface of the faucet (or of the ring when a ring is used) is made slightly conical and with the more contracted part towards the outside of the joint. A hydraulic cement of any suitable kind, but, by preference, such as is hereinafter described, is rammed into the space between the joint surfaces, and forms a ring of a wedge form in longitudinal section, the internal pressure acting on the base of the wedge so as to jam it the tighter the greater that pressure is.—Patent completed.

358 J. HENDERSON, Leith. *Surface condensers and refrigerators.* Dated February 5, 1869.

This consists in entirely surrounding an ordinary condenser or refrigerator with water spaces, and may be carried out in practice by making the condenser with double casings or shells, and by admitting part of the condensing or cooling water between such shells. The invention is most conveniently applicable to surface condensers of the kind fitted with tubes through which the water passes whilst the steam surrounds them, but it may also be adopted in those in which the steam is inside of the tubes and the water outside, and in the latter case there will be three shells or casings, water being between the outermost and the second, and steam between the second and innermost.—Patent abandoned.

359 W. ADAMS, Bow, and W. G. BEATTIE, Surbiton. *Bearing springs.* Dated February 5, 1869.

To some convenient part of the frame or body of the carriage, and at each end of the bearing spring, the inventors secure a scroll iron or hanger having a jaw projecting downwards with holes or slots formed in such jaw to receive two revolving trunnions formed on the sides of a socket tube, through which tube a rod passes secured to the end of the spring by a suitable jaw and pin. On this rod, and bearing against the end of the socket tube, they place a spring of india-rubber, or steel, or other suitable elastic material, such spring being confined at the ends by two metal plates, and secured by screw nuts or collars so as to allow of adjustment.—Patent completed.

360 J. TAYLOR, Birkenhead. *Raising and lowering apparatus.* Dated February 5, 1869.

The inventor provides the apparatus with steam cylinders of long stroke, the piston rods of which are connected either directly (if oscillating cylinders are used) or by connecting rods to a crank or crank plate on the ends of the chain barrel, so that the motion of the piston directly effects the rotation of the barrel without the intervention of gearing.—Patent completed.

361 J. H. JOHNSON, Lincoln's Inn-fields. *Mounting ordnance.* (A communication.) Dated February 5, 1869.

The trunnions of the gun are mounted upon a pair of upright levers, which turn on centres at their lower ends in the body of the carriage, and which levers form the front portion of a perfect parallelogram on each side of the gun composed of the two upright levers referred to, and other upright levers in the rear, and two horizontal rods or links coupling the trunnions with the upper ends of the hinder upright levers. The base of the parallelogram is formed by the main body of the carriage or support. It will be readily understood that the gun may be drawn inwards and simultaneously lowered below the parapet, so as to be completely concealed, this motion being perfectly parallel and the gun preserving the same direction as to aim both in its elevated and lowered position. The recoil of the gun is caused to contract a spring or springs, or elevate a counter weight which shall subsequently produce or assist in producing the movement requisite for elevating the gun.—Patent completed.

362 J. HALFORD, Kingswinford. *Puddling furnaces* Dated February 5, 1869.

Instead of the ordinary fireplace in which the combustion of the fuel is effected, the inventor constructs an oven or chamber without fire bars, on the bottom of which oven the fuel to be burned is supported. The fuel is supplied to the oven by an opening at one side or other convenient part. The air to support the combustion of the fuel may either enter the oven direct from the atmosphere, or be supplied by flues made in the top or roof and vertical walls of the oven. The air passes along the flues at the top of the said oven, descending the vertical flues at the back of the said oven, passes into the said oven through holes in the vertical back wall.—Patent completed.

363 A. CLARK, Chancery-lane. *Mules.* (A communication.) Dated February 5, 1869.

The wool when prepared for spinning is in the condition of roving or prepared sliver wound upon spools. These spools are placed upon drums at the back of the rolls The roving passes from the spools between the rolls, and thence to the spindles, which are in the usual position in the carriage. When the machine is ready to start, the carriage and spindles are at the nearest point to the rolls. When the mule is started, the carriage begins to recede from the rolls, the rolls running at the same time, and delivering the roving at about the same speed as the traverse of the carriage. The rolls continue delivering the roving until the carriage is about half way out. The rolls are then stopped by what the inventor terms the "roller motion," the carriage still continuing out to the end of its traverse. The rolls being stopped and the carriage continuing its way out, the yarn is consequently drawn and made finer.—Patent completed.

364 A. BROWNE, King William-street. *Making stearine.* (A communication.) Dated February 5, 1869.

The fatty substances are melted and treated mechanically with sulphuric acid of 66deg. to 68deg. Beaume more or less, after which they are boiled with water, by which the oxide of glycerye is separated therefrom in a hydrated form, as glycerye water or sulphate of glycerye, and the fatty substances separate by themselves, but still contain traces of sulphuric acid, or rather chemical compounds of the two acids, sulphur stearine and sulphurlain acid, and sulphurpalmitin acid, and afterwards they are repeatedly washed in water until they cease to contain any trace of sulphuric acid for the finest re-action.—Patent abandoned

366 C. G. HILL, Nottingham. *Making rosettes.* Dated February 5, 1869.

The inventor produces rosettes much more readily and advantageously by first causing the band to take a curved or coiled form by corrugating the back or selvage of the band by passing it through crimping rollers. Then in attaching the band to the pad he dispenses in great part with the use of the needle, simply attaching the outer ring or rings to the pad by sewing, and causing the remaining convolutions to adhere by means of gum or cement.—Patent completed.

367 C. S. DAWSON, Thames Ditton. *Elastic stamp.* Dated February 6, 1869.

This stamp is made by taking a stereotype mould in plaster of Paris or papier mache from printer's type or from an engraved surface made in either wood, steel, copper, stone, or type metal. A composition of glue dissolved in glycerine by heat, and when of a suitable consistency, is then poured upon the mould above mentioned, which has been previously varnished and greased in order that the composition may be removed from the mould without injuring any of the lines in the matter from which the impression is taken, and when cold is both elastic and pliable.—Patent completed.

368 H. A. DUFRENE, Paris. *Ice apparatus.* (A communication.) Dated February 6, 1869.

The improved apparatus employed in carrying out this invention, and in which mechanical pressure is the acting agent, is based upon the principle that certain liquid agents, such as methylic ether and ammonia, in evaporising immediately take up from the surrounding bodies the caloric necessary for vaporisation. The consequence

of this action is that it is necessary to collect the vapours produced as soon as they are disengaged, and to reliquefy them in such a manner as to be able to use the freezing agent over again, and the invention consists in the means for so doing.—Patent completed.

369 J. S. OFFORD, Norwich. *Clipping and shearing.* Dated February 6, 1869.

This consists in the use of a fixed comb with an upright rib or flange on each tooth, leaving a receptacle thereon for the teeth of a movable plain comb-shaped holder, by the movement of which the hair, wool, or other material is held between each tooth of the holder and the outer side of each rib or flange of the fixed comb, against which it is brought in contact and firmly held ready to be cut off by the action of a cutting blade moving over the comb and holder, in a direction from the base to the top of the ribs or flanges.—Patent completed.

370 W. R. LAKE, Southampton-buildings. *Puddling furnaces.* (A communication.) Dated February 6, 1869.

These improvements are chiefly designed for the kind of puddling furnaces in which the mass or ball of iron is formed by the mechanical action of a rotary refining chamber. The first part of the invention consists in a form of the rotary refining chamber, adapted to hold and properly preserve the fettling, and so constructed as to be preserved from overheating by means of water. The second part of the invention consists in making removable that portion of the flue which fronts the rotary refinery so as by turns to discharge the functions of a flue and of a door. The third part of the invention consists in the combination of a water back with a rotary refining chamber.—Patent completed.

371 R. SNOOK, New-steeet, Horsleydown. *Cocks, taps, and valves.* Dated February 6, 1869.

This consists of a chamber or barrel of suitable form and material, fitted to receive a conical plug, which plug is disposed horizontally and centrally within the barrel. This conical plug is made hollow and has the larger end of the cone open, which opening serves for the admission of the fluid, which fluid has its exit through an orifice left in the side of the conical plug.—Patent abandoned.

372 J. C. SHAW, Patricroft. *Cutting wire.* (A communication.) Dated February 6, 1869.

The machine forming the subject of this invention consists of a pair of cutting discs, both of which are perforated with any number of holes of different diameters to suit the size of the wire or rod to be cu . These holes are drilled in a slightly diagonal direction in order that the end of the wire or rod may be perfectly square when cut. One of the cutting discs is cast in a case, which is secured to the floor or to a bench or held in a vice, and the other disc is held up to the cutting face by the cover of the case, both parts of the case being bolted together. The second cutting disc has a projecting tongue, against which a cam at the end of a lever acts. This lever is hinged to the case, and through the lever passes the spindle of an adjustable gauge.—Patent completed.

373 J. T. EDMONDS, City-road. *Cattle medicine vessels.* Dated February 6, 1869.

This consists of an instrument or apparatus constructed as hereafter described for administering drinks to horses or other cattle. It is composed of a tube, by preference made of metal, having at its lower end a piece of flexible tubing, but not necessarily, as the whole tube may be made of metal. This tube is intended to contain the drink it may be desired to give an animal, and its size is regulated according to the amount it is to contain—a half pint or pint, for example. In this cylinder or tube the inventor places a piston or plug connected to a long rod passing through a stuffing box at the other end, and surrounded by a second tube outside and beyond the first and larger tube; a spring is placed in the smaller tube and round the piston or plug rod, which always gives the rod a tendency to escape from the tube.—Patent abandoned.

374 H. A. BONNEVILLE, Paris. *Solid broth compositions.* (A communication.) Dated February 6, 1869.

A ball of salt is covered in successive layers and in proportional quantities with the following substances in the following order, viz.:—Extract of meat, grease, dissolved gelatine, and aromatised with a proportional quantity of vegetable extracts.—Patent completed.

375 C. D. J. SEITZ, Bury. *Recovering soda from waste lyes.* Dated February 6, 1869.

This consists in placing a hearth or roaster and a furnace in close connection, so that the residuum is transferred to the furnace without contact with the atmosphere. The hearth and furnace communicate with each other either back to back or otherwise by an opening occasionally provided with a damper. The furnace is supplied with pans, in which the lyes are evaporated, and is provided with firebars; there is an opening between one end of the lower pan and the wall, while at the other side there is a flue leading to the chimney.—Patent completed.

376 E. MELDRUM, Dechmont. *Treating paraffin.* Dated February 6, 1869.

An apparatus, such as an iron tube or a common retort such as is used in the distillation of shale or coal, is built up over or alongside of a fire, so that the temperature can be so regulated as to attain a range of temperature not exceeding a visible red heat, and in order that a large heating surface may be obtained, such apparatus may be filled with broken stones, spent shale, or other refractory substance in a divided state. The heavy oil or oils or the melted paraffin are to be run slowly in at one end of a retort or decomposing tube, or are passed through the same in a state of vapour from a still or distillatory apparatus connected therewith, and the products thus resulting are condensed by passing off through a cooling worm or condenser proceeding from or connected with the other end of the retort.—Patent completed.

377 T. HARRISON, Lincoln. *Drills.* Dated February 6, 1869.

This consists in arranging the corn, seed, or manure box or reservoir in such manner that it may remain constantly in a level position, whether the drill is being moved up hill or down hill or over undulating land, so that the delivery of the corn, seed, or manure will not vary.—Patent abandoned.

378 B. WALKER and W. TILSON, Lenton, Notts. *Jacquards.* Dated February 6, 1869.

The inventor employs a reading machine capable of making its own fabric, which fabric forms a substitute for the cards. He works paper from a circular or other shaped cylinder, movable or otherwise, such paper being independent of the fabric made in the reading machine. The jacquard wires which he employs are lifted independently of the motion of the cylinder, and the fabric and the paper while at work are kept in sufficient tension by rollers or by other equivalent mechanical contrivance.—Patent completed.

379 E. W. HAWES, Clintarf, Dublin. *Buoys and sea marks.* Dated February 8, 1869.

This consists in forming or making a buoy or other floating sea mark of such materials as that it shall be more buoyant than any at present in use, so that in the event of its receiving any of the injuries consequent to such sea marks, it shall not be lost, but from its being composed of floating materials any or all of its parts individually or collectively can be picked up and recovered.—Patent abandoned.

380 T. NICHOLS and J. PARR, Talke, Chester. *Signal bells.* Dated February 8, 1869.

This consists in making signal bells for collieries and for other purposes with a tumbler catch acting on the striker or hammer and in making the bell (or apparatus for giving forth sound) of metal in the shape of a fork or ∩ shaped—that is to say, U inverted or otherwise.—Patent completed.

381 L. S. and A. SECKBACH, Wiesbaden, Prussia. *Preserving beer.* (A communication.) Dated February 8, 1869.

Carbonic acid gas is generated and caused to act upon the liquid or beverage to be treated so as to preserve it and improve its quality, and it also may aid in forcing it up to the required level in order to be discharged.—Patent abandoned.

382 E. J. D. FOSSARD, Paris. *Cyster pump.* Dated February 8, 1869.

The inventor dispenses with any bifurcation of the suction of delivery tubes, and maintains them in a right line with each other or nearly so. He places the pump at any convenient point on this right line, connecting it at one end with the suction pipe and at the other end with the delivery pipe. He forms the pump simply of a straight tube, having at its lower extremity a loose valve opening upwards from the suction tube, and at its upper end another loose valve opening upwards into the delivery tube.—Patent abandoned.

383 R. W. ROW, Alton, Hants. *Solitaires, links, and fasteners.* Dated February 8, 1869.

This consists in the construction of a screw fastener and nut, with hook combined for an eyelet hole in the glove band, or belt.—Patent abandoned.

384 J. H. JOHNSON, Lincoln's Inn-fields. *Steam engine governors.* (A communication.) Dated February 8, 1869.

It is proposed to construct the governor valve in the form of a triple disc valve, the three discs being of equal size, and connected together by spiral or other arms or rods. This triple disc valve works through two valvular openings made in the two upper horizontal portions of an S-shaped diaphragm or partition cast inside a closed valve chamber, the spindle of the valve working through a stuffing box and being coupled to the governor spindle.—Patent completed.

385 O. SARONY, Scarborough. *Photography.* Dated February 8, 1869.

The inventor takes a small negative portrait, and enlarges the same to any suitable extent or variation upon glass, either by sun or artificial light, which portrait he backs up with, by preference, rough drawing paper or other suitable equivalent material, on which has been lithographed hatched, shading, or free-hand lines or tint, such lining or tinting being so arranged on the paper backing as to properly surround the transparent picture on the glass when placed before it.—Patent completed.

386 W. R. LAKE, Southampton-buildings. *Puddling furnaces.* Dated February 8, 1869.

This consists in mixing an alkali or alkalies or lime, separately or combined with common salt, with the cinder of the puddling or boiling furnaces whilst in a fluid state, or when pulverised after tapping from the furnace. The mixture is to be used as a "fix" for the puddling or boiling furnace; alkali or alkalies, lime or salt, may be mixed with pulverised or melted iron ore for "fixing" puddling furnaces.—Patent abandoned.

387 W. R. LAKE, Southampton-buildings. *Knitting machines.* (A communication.) Dated February 8, 1869.

This consists in the arrangement of two conical needle carriers placed one opposite the other, connected together by gear wheels, and constructed in such a manner that the needles of one needle carrier work between those of the other, and that by the combined action of the needles in the two carriers an elastic fabric can be produced of one or more colours. Also in the arrangement of cam cases in combination with the needle carriers, in such a manner that by the action of the cams in the cam cases, the desired rising and falling motion is imparted to the needles.—Patent completed.

388 B. HUNT, Serle-street, W.C. *Manometric-barometric apparatus.* (A communication.) Dated February 8, 1869.

This apparatus chiefly consists of a metallic lens formed by two very thin membranes, and having a glass tube connected to any part of its circumference. If this lens be filled with liquid and submitted to an external pressure the liquid which fills the same will be forced into the glass tube to a distance which will be longer in proportion as the internal diameter of the glass tube is smaller than the volume of the lens. The latter is enclosed in a case connected by means of a pipe with the pressure to be indicated. If the pressure to which the lens is submitted externally does not deflect the membranes beyond the limits of their elasticity as soon as the pressure ceases they will return to their original position and the liquid will re-enter the lens.—Patent completed.

389 H. J. RICHMAN, Porchester-terrace, W. *Fans.* (A communication.) Dated February 8, 1869.

The inventor makes a turbine or fan with two discs, the one solid or close, the other open in the centre to admit the air. A ring or flange is formed round this opening and revolves air-tight in an opening at the front end of the casing. The spindle or shaft is fixed in the centre of the solid disc and passes through the opening in the other end of the turbine or fan without being attached to it to a bearing in which this end of the spindle which carries the pulley turns.—Patent completed.

390 F. JENKIN, Fittis-row, Edinburgh. *Electric light.* Dated February 8, 1869.

The light is produced by a rapid succession of sparks due to successive charges and discharges of a condenser charged directly from a voltaic battery without the intervention of any induction coil. When the invention is used for this purpose the condenser is on the beacon and the battery on shore is connected with a terminal on the beacon by a submarine cable or aerial wire. The condenser is charged and discharged by a tongue or contact maker moving backwards and forwards between the battery terminal and an earth terminal.—Patent completed.

391 W. A. LYTTLE, Hammersmith. *Magneto-electric apparatus.* Dated February 9, 1869.

In order to obtain the intermittent suspension or rather short circuiting of the attractive force of a permanent magnet or continuously acting electro-magnet, the inventor connects the opposite poles of the permanent magnet by means of a stationary armature of any convenient shape, but the longer the better up to the length of the permanent magnet; and he surrounds this armature at one or more points preferably at or near its two extremities with a coiled conductor of any suitable kind, so that at pleasure it can be converted into an electro-magnet.—Patent abandoned.

392 R., G., and C. W. PHELPS, Birmingham. *Feeding bottles.* Dated February 9, 1869.

This consists in applying to the elastic tube of the feeding bottles a clamping or regulating apparatus whereby the elastic tube may be compressed and wholly or partially closed at pleasure, and the quantity of liquid capable of passing through it in a given time thereby regulated or the passage of liquid altogether prevented. The clamping or regulating apparatus which it is preferred to employ consists of a frame through which the elastic tube is passed. A screw passes through one end of the frame and carries at its lower end a plate and at its upper end a nut or head.—Patent abandoned.

393 G. REES, Holloway. *Devices on glass.* Dated February 9, 1869.

The object of this invention is to produce ornaments or devices by vitrifying pounded glass upon glass and glazed ware. Powdered glass, either dry or as a paste, is taken, and the cavities of a mould are filled with it, if a design is required or the surface of a plain mould is to be covered. The mould is then built up to the required depth with the same material to form a backing. The material is then vitrified in a kiln in the ordinary manner in the mould or not. When a coloured design is required the powdered glass is mixed with metallic or mineral oxides.—Patent abandoned.

394 W. WILLIAMS, Sneinton Elements, Nottingham. *Communicating in trains.* Dated February 9, 1869.

The inventor attaches a tube shaft or equivalent contrivance to the whole length of a railway carriage. At each end of this shaft is inserted a rod, and in the space between these rods are placed springs or their equivalents, which press or force the rods out of the tube to any required distance to meet the ends of the rods affixed to the adjoining carriages. At the outward end of each rod is affixed a disc or buffer, the outward face of which is formed with raised segments or their equivalents which gear with the discs or buffers of the adjoining carriages. On the shaft adjoining the guards' and drivers' carriages is placed a wheel or its equivalent, and in a position suitable for the convenience of the guard and driver is placed another wheel which, when turned, will communicate rotary motion to the shaft. On this last-mentioned wheel or its equivalent is fixed a camber wheel with which is connected a rod attached to a bell.—Patent abandoned.

395 J. and G. W. DENNELL, Leeds. *Boot machine.* Dated February 9, 1869.

The inventor employs the usual kind of ring or stamp knife, that is, a knife with its edge formed to the required shape of the sole or heel to be cut out, and so as to be pressed through the material, but in constructing this knife he forms the interior thereof wider at its back than its edge, so that the soles or heels as cut will easily pass through the knife. This knife he fixes with its edge upwards by means of adjustable clamps upon a suitable bed or table, and above it he mounts in suitable framework a reciprocatory stem or slide bar upon which he fixes a block or presser of wood or other suitable material to be pressed into contact with the edge of the knife and then removed from it; motion to the presser may be given from a rotary shaft by crank or eccentric and rod, or by cams, tappets, or other suitable means.—Patent completed.

396 J. WILKINSON and W. SCOTT, Bradford. *Looms.* Dated February 9, 1869.

This consists in the application of a toothed wheel to the beam to gear into another toothed wheel of smaller diameter mounted on a stud fixed to the loom frame, and to which stud wheel is fixed a brake pulley for a cord or belt to pass around, and then be attached to a weighted lever. This lever is provided with a catch taking into the toothed wheel fixed on the beam, so that the attendant by operating the lever may lift the weight and thereby remove the pressure from the brake pulley and let slack the warp, and also by means of the catch set up the beam so as to increase the tension of the warp.—Patent abandoned.

397 G. WHITE, Queen-street, Cheapside. *Automator.* (A communication.) Dated February 9, 1869.

This consists in imparting a suitable rotating motion to one or more wheels fixed parallel to each other on an arbor revolving in suitable bearings, the rotating motion of the wheels being kept up so as to allow of applying the revolving motion of the arbor as a prime mover for driving machinery.—Patent abandoned.

398 W. MITCHELL, Stacksteads. *Felt carpeting.* Dated February 9, 1869.

This relates, first, to making felt carpeting with three layers or slivers, the central one of which is of an inferior or different material to the front and back layers, which latter may be both of the same quality or material, or also different from each other. In carrying out this part of the invention the inventor employs three separate carding engines and folders arranged side by side or otherwise, and each delivering its own slivers on to the same "batt cloth," but superseded, that is one over the other, so that the upper one may be of fine wool, the lower one of inferior wool, and the central or middle one of almost any inferior or other fibrous material or mixture of materials.—Patent abandoned.

399 L. A. C. ST. PAUL DE SINCAY, Paris. *Roofing tiles.* Dated February 9, 1869.

The inventor provides the tiles with lateral flanges by which they are connected together, and also with ears for securing the tiles to the framing of the roof. The ears are fixed at one corner of the tiles, while the ears are made to hook on to the flanges and are also secured by nailing to the rafters. The number of these ears varies accord-

ing to the size of the tiles; by making the tiles of small dimensions the inventor is enabled to use much thinner and cheaper metal than is the case when the tiles are made of considerable size.—Patent completed.

400 G. CRITCHLEY, Liverpool, and H. B. FOX, Oxton. *Rocking chairs.* Dated February 9, 1869.

This consists in applying to the bottom or feet of any ordinary chair or similar article a spiral or other spring or any elastic material, preferably made with a broad, flat surface at the bottom, and attached to the chair or other article by a piece similar in form to a castor-socket or castor-plate, to which the spring or other elastic material is made fast.—Patent abandoned.

401 G. F. G. DESVIGNES, Tulse-hill, S. *Steam boilers.* Dated February 9, 1869.

The inventor increases the heating surface of the boiler so as to admit of steam being got up rapidly by the application of syphon-like pipes inserted into the crown of the firebox. Each pipe is fixed at one end into the crown of the firebox, and after projecting a convenient distance into the firebox is bent round and led up again into the boiler, when it is made to ascend almost to the water level of the boiler. A constant circulation then takes place in the syphon pipes so long as the fire is burning, the heated water ascending by the longer leg of the syphon and the cooler water descending from the boiler by the shorter leg.—Patent completed.

APPLICATIONS FOR LETTERS PATENT.

Dated August 24, 1869.

2511 J. Frengley, Dublin. An improved tell-tale clock.

2512 Z. Colburn, Bedford-street, Westminster. Improvements in the construction and mode of launching subaqueous ways.

2513 J. Williams, South Castle-street, Liverpool. An improved junction of barrel and action for breech-loading firearms and sporting guns, with self-acting exploded cartridge extractor.

2514 H. Taylor, Kensington, Middlesex. Improvements in velocipedes.

2515 F. Oakley, Toronto, York, Ontario, Canada. Holding firmly and securely in their place bolt nuts.

2516 J. E. Hodgkin, Liverpool. Improvements in machinery for breaking the woody parts of flax, straw, and other similar fibrous plants, and for scutching or removing such parts therefrom.

2517 T. Briggs, Manchester. Improvements applicable to machinery for spinning and doubling cotton and other fibrous materials.

2518 J. D. Nietscke, Somerset, Perry, Ohio, U.S.A. Preserving dead bodies.

2519 J. Valters, Great Dunmow, Essex. An improved agent for fining and clarifying ale and other fermented liquors.

2520 T. Webb, Clarence-road, Bow, Middlesex. Improvements in the ventilation of mines.

Dated August 25, 1869.

2521 W. J. Cockburn-Muir, Westminster. Improvements in the construction of the permanent way of railways.

2522 R. Maynard, Whittlesford, Cambridgeshire. An improvement in portable chaff-cutting machines.

2523 C. Mackay and T. K. Wheeler, jun., Clarendon-place, Belfast. Improvements in cops for wefting and warping purposes, and in machinery for making and in shuttles for containing the same.

2524 T. Shakespear and G. Illston, Birmingham. Improvements in sewing machines.

2525 O. and F. H. Varley, Stonecutter-street, Farringdon-street, Middlesex. Improvements in instruments for transmitting and recording electric signals, part of the invention being applicable to other purposes.

2526 C. Cerisier, Mung-sur-Loire, France. A system of ventilation and airing of millstones.

2527 T. Coley, Bower Farm, Maidstone, Kent. Improved means or appliances to be employed in the cultivation of hops.

2528 W. R. Lake, Southampton-buildings, Chancery-lane. Improvements in braiding or platting machines.

2529 H. Call, Concord, Merimac, New Hampshire, U.S.A. An improved mode of, and machinery for, obtaining and applying motive power, more especially designed for the transmission of the same to long distances.

2530 G. Zoeh and A. Lehmann, Havre, Department of the Seine Inferieure, France. A novel process of manufacturing yeast or artificial ferment.

2531 A. F. Cederwaller, Viborg, Finland, and A. F. Westerlund, Stockholm, Sweden. Certain improvements of the porcelain-faience and pottery manufactory.

2532 W. Brown, St. Mary-street, Portsmouth. Improvements in the mode of constructing and disposing ships' cabins to prevent sea sickness, the said improvements being also applicable to gun carriages on board ship.

Dated August 26, 1869.

2533 C. D. Abel, Southampton-buildings, Chancery-lane. Improvements in the means and apparatus for separating or dividing the carded fleece into slivers in carding machines for all kinds of filaments.

2534 H. P. Stephenson, Abingdon-street, Westminster, E. G. Bartholomew, Chepstow Villas, York-road, Upper Holloway, Middlesex, and R. King, St. Mary Axe, City. Improvements in lighting and extinguishing gas lamps.

2535 B. Hunt, Serle-street, Lincoln's Inn. Improvements in steam condensers, and in supplying steam generators with water.

2536 H. Yates, Rue Lafayette, St. Pierre les Calais, France. Improvements in the manufacture of lace on bobbin net or twist lace machinery.

2537 W. R. Lake, Southampton-buildings, Chancery-lane. Improvements in machinery for carding and spinning fibrous materials.

Dated August 27, 1869.

2538 E. A. Cowper, Great George-street, Westminster. Improvements in treating cast iron for the production of wrought iron and steel therefrom, and in apparatus employed for that purpose.

2539 A. Moncrieff, Culfargie, Perthshire. Improvements in the means and apparatus for absorbing, storing, and utilising the force of recoil of ordnance, and in applying and working covers, roofs, or shields to gun platforms.

2540 J. M. Stanley, Sheffield. Improvements in the manufacture of iron and steel, and in furnaces and converting crucibles used in connection therewith.

2541 O. Vivier, Sekforde-street, Clerkenwell, Middlesex. Improvements in means or apparatus for measuring and indicating the distance travelled by vehicles.

2542 F. J. Drechsler, Cockspur-street, Westminster. Improvements in stoves and grates or apparatus for cooking, heating, and other stove or grate uses, with rotary motion arrangements and with appliances for rendering the same useful for fumigating, refrigerating, sifting, winnowing, churning, cutting, and other purposes where such rotary motion arrangements may be capable of being used.

2543 W. E. Gedge, Wellington-street, Strand. A novel construction of railway sleeper.

2544 B. Hunt, Serle-street, Lincoln's Inn. Improvements in machinery or apparatus for hulling, cleansing, and polishing or preparing coffee, rice, and other berries or grain.

2545 J. Toychenne, Rue Pregon House, Small Heath, near Birmingham. Improvements in, or additions to, springs for mattresses, sofas, chairs, and other articles of furniture.

2546 E. A. Campbell, Bilton-road, Rugby, Warwickshire. The extraction of essence of roasted coffee by a machine called coffee essence extractor.

2547 W. R. Lake, Southampton-buildings, Chancery-lane. An improved method of, and apparatus for, rendering and refining lard, tallow, and other fatty and oleaginous matter.

2548 J. Flon and W. Charlet, Brussels, Belgium. A new system of sash or framework for landau and landaulet carriage doors.

2549 S. C. Lister, Bradford, Yorkshire. Improvements in looms for weaving pile and other fabrics, and in yarns for pile fabrics, and in sizing them.

2550 R. C. Rapier, Westminster Chambers. Improvements in railway water cranes.

2551 J. Ritchie, Stonefield-street, Barnsbury, Middlesex. Improvements in the construction of tents and sunshades or weather protectors suitable for carriages and other vehicles.

Dated August 28, 1869.

2552 C. Duff, Russell-street, Bermondsey, Surrey. Improvements in the manufacture of paper pulp and paper.

2553 T. S. Blair and F. Ellerhausen, Southampton-buildings, Chancery-lane. Improvements in treating conglomerates of cast iron and other substances.

2554 J. Butterworth and J. Ainsworth, Bury, Lancashire. Improvements in mangling and squeezing machines.

2555 J. Spencer and J. Consterdine, Hollingwood, near Manchester. Certain improvements in portable drilling machinery, parts of which are applicable to machines for other purposes.

2556 J. Holdsworth, Kingston-upon-Hull. Improvements in apparatus for loading or discharging grain, coals, ballast, or other materials.

2557 R. H. Herriott, Skegby, Nottinghamshire, C. Plumbe, Mansfield, Nottinghamshire, and W. A. Plumbe, Sutton, Ashfield, Nottinghamshire. Improvements in communicating between passengers and the guard and driver of railway trains, and in the machinery or apparatus employed therein.

2558 J. Brown, Padiham, Lancashire. Improved means of, and appliances for, facilitating the exercise or riding of bicycles or velocipedes.

2559 C. S. W. Muir, Kilmarnock, Ayrshire. Improvements in safety apparatus for steam boilers; in apparatus to provide for and regulate the admission of air to steam boiler and other furnaces; and in apparatus to provide for the escape of water from steam pipes.

2560 R. O. Robinson, Avenham-terrace, Preston, Lancashire. An improved construction of stove or firegrate.

2561 J. Loader, Upper Clifton-street, Worship-square, Middlesex. Improvements in rotary engines and pumps.

2562 R. Priestley, London Wall, City. Improvements in fastenings for gloves.

Dated August 30, 1869.

2563 L. Goldberg, Love lane, City. Improvements in watches, toy watches, personal ornaments, purses, pocket-books, walking sticks, and certain other portable articles.

2564 R. J. Westley, Camden-road, Camden Town, Middlesex. Improved methods of constructing, converting, and using billiard and other tables.

3565 W. Young, Foyle-road, Londonderry. An improved method of clarifying and refining butter and other fatty matters.

2566 T. Cattell, Strand. An improved method of treating wood for the production of paper pulp.

2567 W. F. Williams, Broad-street, Golden-square, Middlesex. Improvements in boxes for holding jewellery and other articles.

2568 W. Winter, Leeds. An improved metallic driving belt or band, and the means of manufacturing same, also the application thereof and other metallic belts for driving sewing machines.

2569 W. E. Newton, Chancery-lane. Improved machinery for manufacturing nails, brads, and other analogous articles.

2570 H. E. Newton, Chancery-lane. Improvements in furnaces.

2571 C. R. Stooke, Teignmouth, Devonshire. Improvements in safety cages for mine shafts, which improvements are also applicable to lifts for warehouses, hotels, and for other places.

PROVISIONAL PROTECTION FOR SIX MONTHS

Has been granted upon Specifications bearing the following numbers:—

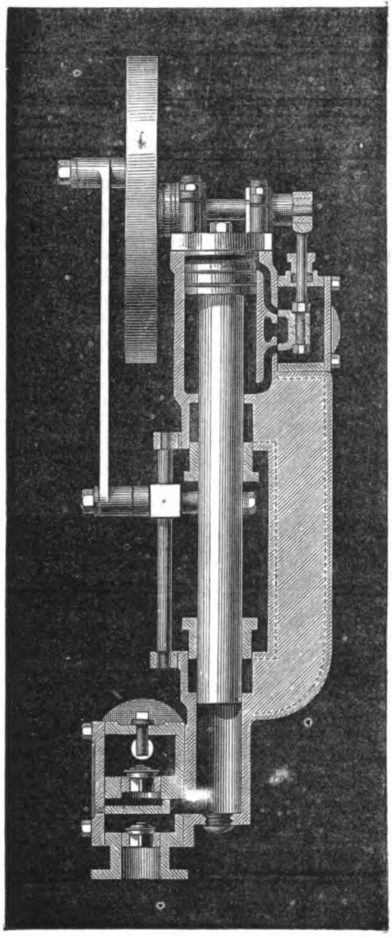
NOTICE.—Having received communications from persons residing in the country to the effect that difficulties are occasionally experienced by them in obtaining copies of printed specification from the Patent Office, in consequence of the varying nature of the postage thereon, our readers are informed that upon receipt from them of particulars of the specifications they require, together with a remittance for the cost and approximate postage thereof, we shall be happy to procure and forward such specifications free of all further charge. Sums under Five Shillings may be remitted in postage stamps, for sums above that amount a Post Office Money Order should be sent, payable to ROBERTSON, BROOMAN, and CO., Patent Department, 166, Fleet-street, London, E.C., to whom all communications upon the subject should be addressed.



ALEXR. WILSON & CO.,

ENGINEERS,

VAUXHALL IRON WORKS,

NINE ELMS, LONDON, S.W.,

MANUFACTURERS OF

IMPROVED DONKEY PUMPS, INJECTORS, SAFETY VALVES, STOP VALVES, AND BOILER MOUNTINGS OF EVERY DESCRIPTION.

PRIZE MEDAL, HAVRE MARITIME EXHIBITION.

The attention of Engineers is particularly called to the "Vauxhall" Improved Donkey Pumps and Injectors, which are now used by all engineers. They are the best Boiler Feeders ever brought before the users of steam power, and for boilers supplying steam to apparatus, other than the steam engine, they are indispensable, while they are rapidly supplanting the feed pump on the engine itself, as they dispense with the necessity of running a large engine merely to get a little water into the boiler. They are at work on board ships and steamers, in breweries, distilleries, gas works, tanneries, hemical works, and in every situation where single, double, and three-throw pumps have hitherto been used.

N.B—They are proportioned to draw 15ft. and force into the boiler supplying steam to them; when they draw more than 15ft. the rams have to be made smaller. In pumping water they will throw it 2ft. high for every pound pressure of steam in the boiler.

REDUCED PRICE LIST

Size.	Diameter.	Stroke.	Gallons thrown per hour.	Horse power of boiler supplied.	Price. £.	s.	d.

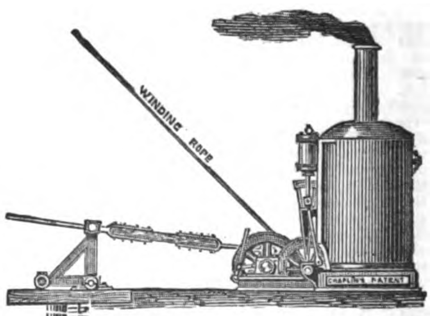
Prize Medal, International Exhibition, 1862.

CHAPLIN'S

PATENT PORTABLE

STEAM ENGINES,

FOR PUMPING AND WINDING.



SPECIALLY ADAPTED FOR PITS, QUARRIES, &c.; SIMPLE AND STRONG; REQUIRE NO FOUNDATION OR CHIMNEY STALK, AND ARE EASILY ERECTED OR REMOVED.

Sizes, from 2 to 30-horse power

Stationary Engines, 1 to 30-horse power, with or without gearing.
Steam Cranes, 30 cwt. to 20 tons, for Wharf or Rail.
Hoisting Engines, 2 to 30-horse power, with or without jib.
Contractors' Locomotives, 6 to 27-horse power.
Traction Engines, 6 to 27-horse power.
Ships' Engines, for Winding, Cooking, and Distilling, passed by H.M. Government for half-water.
Steam Winches. Engines and Boilers for Light Screw and Paddle Steamers.

ALEXANDER CHAPLIN & CO.,

CRANSTON HILL ENGINE WORKS,

GLASGOW. A 51

THE

MECHANICS' MAGAZINE.

LONDON: FRIDAY, SEPTEMBER 10, 1869.

ON THE REPORT OF THE METEOROLOGICAL COMMITTEE.

IN resuming our criticisms upon the above report, we will first refer to the intelligence respecting storms sent by the office to places sanctioned to receive it gratuitously by the Board of Trade. "The messages consist of an order to hoist the drum accompanied by a brief explanation of the reasons why it is to be hoisted. The message is posted up at many stations as soon as it is received for the public to read. It continues in force for thirty-six hours, and no longer, from the time of its receipt, unless modified by subsequent telegram, which is frequently sent, either when the danger is known to have passed over or when there are signs of the approach of another storm." "The system of telegraphy of storms to foreign countries is not uniform in its character. To the Marine Ministry in Paris, the same messages are sent as to our own south coast and to Jersey; Holland and Hamburg receive special telegrams similar to those which are sent to the Underwriters' Association, of Liverpool. They convey the amount of atmospherical disturbances whenever the difference of readings over the same definite area exceeds 0·8in. The authorities at Hamburg hoist a drum at that port and at Cuxhaven whenever a telegram is received from London. These stations are thus precisely similar to those on our own coasts. In return for this intelligence immediate intimation is sent to London from France, Holland, and Hamburg by the meteorological authorities in their respective countries whenever a storm strikes any part of their coasts."

The ports on the east coast of England, we are informed, "can usually be warned of a storm in ample time, owing to the general tendency of storms to advance from the westward." These are the most important ports to warn, and when omissions occur, the results may be excessively serious. Thus early on the 16th of June last, a gale which did great havoc in the North Sea was not announced at all from London. The Rev. F. Stow, writing from Shields, says:* "A thunderstorm occurred on the 15th. The barometer had sunk at 9 a.m. to 29·04; at 3 p.m. clouds gathered; and between 3h. 30m. and 5h. 30m. 0·66in. fell, the wind veering from S.E. to W. Soon after midnight a terrific gale from N. awoke everyone. It is remarkable that the coming storm escaped the vigilance of the Meteorological Office, although their returns for the 15th show a rapidly increasing difference of barometrical pressure between stations in the W. and E. The absence of warning doubtless increases the number of disasters. Next morning rain to the amount of 1·02in. was measured for twenty-four hours, and the thermometer was as low as 44deg."

As the Committee claim to have improved the means and deductions for predicting storms, a further advance towards the system pursued by Admiral Fitzroy seems desirable. Prediction may be easily derided, but if the strength of wind cannot be forecast with so close an approach to certainty as direction, for time and place, there is always some satisfaction to the seafaring class in being put on their guard against a gale which may happen to-day or to-morrow, and cause devastation to shipping from the violence of its force. If the Committee will announce nothing but facts, it seems to us that more frequent reports from the coasts are occasionally desirable, besides the usual once or twice a day, and we should like to have a clearer understanding of the principles upon which the orders for hoisting the drum are issued. Are they sent indiscriminately to all the signal stations, and if so, what satisfaction is there in knowing that atmospheric disturbance exists somewhere on the British Isles, unless people are told where, whither it may extend, how rapidly, and with what result? Only the central office receives the data necessary for arriving at these particulars, and, therefore, the duty of giving the information can only be expected from it. When the Committee commenced their system of telegraphing weather facts, they thought it necessary to establish a check system of observation through the Coastguard. We could never learn why this was deemed expedient, and now these observations have been discontinued.

* Symons' Monthly Meteorological Magazine for July 1869.

It appears to be in contemplation to publish a daily weather chart, but we cannot anticipate its utility. Printed matter cannot be delivered with sufficient despatch to announce the arrival of gales from one place to any other. The office must confine its attention to its main duty, that of giving our seamen, fishermen, and pilots premonitory notice of storms. We are the more concerned in urging this because the Director of the office, Mr. R. H. Scott, has reported to the Committee very favourably upon the indications afforded for foretelling strong winds.

A few remarks as to what is being done for meteorology inland. The committee have established observatories at Kew, Falmouth, Valentia, Armagh, Stonyhurst, Glasgow, and Aberdeen. These have in two years cost the country £7,268, notwithstanding they were founded upon establishments already in existence. We hope they will prove worth the cost of maintenance. The report shows that stringent care has been taken to ensure efficient scientific superintendence, and opens out to the mental view the extraordinary amount of labour that will be requisite to work up and properly utilise their records. "Specimens of proposed forms of publication of the actual barograms, thermograms, and anemograms have been lithographed and distributed to meteorologists in order to elicit suggestions as to their discussion. The calculation of meteorological mean results from the tabulations has been commenced."

A closing remark in praise of the businesslike manner in which the sum voted is accounted for seems deserved. The outlay on instruments has been reduced by recalling those that were either superabundant or misapplied, and a careful regard to economy with efficiency seems generally kept in view. Knowing the tendency of government departments to overspend their votes, it is gratifying to find that but for the expense of furnishing a new office and moving to it, the expenditure would have been considerably less than the £10,000 voted for the year.

VISIT OF THE SOCIETY OF ENGINEERS TO THE BECKTON GAS WORKS.

AT a time when so many of the industrial and manufacturing establishments that were reared on the banks of the Thames have been compelled to suspend operations and close their doors, it is gratifying to witness the construction of works and the erection of premises, on a scale of magnitude hitherto unparalleled, with the same object in view. It is not, however, the vastness of the undertaking, promising as it does employment for a large number of persons, that is its most important feature, but the fact that the employment must by the very character of the enterprise be of a permanent nature. Hence arises the difference—a difference which closely concerns our working classes—between manufactories intended for the production of necessaries and those which fabricate articles for which the demand is uncertain and capricious. Take a shipbuilding yard for example. To-day it may be "full of people," to-morrow "left unto you desolate." During the last three years how many instances of such desolation have not occurred in the vicinity of the locality we are alluding to? A run "down stream" reveals to the eye empty sheds, deserted workshops, neglected wharves, and abandoned premises. The ear listens in vain for the whirr of the wheel and the ring of the anvil; the "hum of men" is no longer borne on the breeze, and the silent waves return no echo to the voiceless shores. Under these circumstances, the project in progress of execution by the Chartered Gas Company should be regarded in a very encouraging light. The object it has in view is not the manufacture of an article the demand for which might at one moment be almost unbounded and at the next diminished to *nil*, but the preparation of a product which at the present time may be considered as a necessity and indispensable to the comfort and convenience of mankind.

At an early hour in the afternoon of Friday last, a large party of the Society of Engineers visited the site of the new gas works at Beckton, and were received by Mr. Wyatt, the resident engineer for the company, and Mr. J. Aird, one of the firm of the contractors. The steamer "Sibyl" was chartered for the outward and homeward voyages, and the party included, among others, the President of the Society, Mr. F. W. Bryant; the Hon. Sec., Mr. A. Williams; the Secretary, Mr. G. Harris; Mr. Sanders, Mr. Cook, Mr. Cargill, C.E., Mr. Walker, &c. Making their way through the scaffolding and timbering, the party reached a temporary platform laid on some of the cast-iron cylinders which carry the pier. As yet, the pier can only be said to be "lined out," as some of the cylinders have been "got down," while of others, the position only is determined. The method of sinking these cylinders is very simple, and is one that has been employed in numerous similar situations. It consists in excavating the ground from the interior, and allowing the consecutive sections to sink by their own gravity. If necessary they can be weighted, should any obstacle obstruct their descent, and should they get fast, the aid of a diver is called in to ascertain the cause. Being 6ft. in diameter, these cylinders offer great facilities for carrying on the sinking operations. The separate lengths are 1¼in. in thickness, with flanges on the inside, through which they are bolted together. As it is necessary to carry them down about 10ft. into the hard gravel, they are sunk some 30ft. below the Ordnance datum, and their total height is not far short of 60ft. The superstructure will consist of wrought-iron girders fixed on the cylinders, and the pier will form a direct communication between the river and the retort houses. It projects at right angles from the river wall, and after continuing in this direction for about 400ft., it turns suddenly "up stream" for nearly double that distance. The coal will be raised by steam or hydraulic power from the barges into trucks on the pier, which will run from it along a viaduct, which forms, in fact, a continuation of this pier, into the retort houses. There is nothing remarkable about the river wall. It extends for nearly 1,000ft. of the 1,500ft. frontage belonging to the company. It is built of brick coped with stone, and protected in the usual manner by fender piles, which are bolted right through the wall in a secure and substantial manner. The gas having been made will pass into gasholders which have a diameter of 180ft., and the united contents of the four will amount to 4,000,000 cubic feet. To supply these enormous reservoirs, the retort houses, which are also four in number, will contain 1,080 retorts, each of

which is 20ft. in length and capable of being charged at both extremities. The main pipes are 4ft. and 3ft. in diameter respectively, and the operation of laying them was inspected by the party. They were conveyed to the spot over a light railway which has been laid down on a road which will eventually connect the gas works with a point on the Barking-road. In consequence of the isolated nature of the locality, it was necessary to construct this road in order to effect inland intercommunication. An inspection of the lithographed plans and drawings furnished satisfactory evidence that some attention had been paid to æsthetical principles, a point commonly neglected by engineers. Although £600,000 is a considerable sum of money, even in these days of large estimates, yet when it is borne in mind that the project is completely metropolitan in character, it is a small one in comparison with the capital raised for other schemes, which, moreover, were not based upon so sound a financial or commercial foundation. Solidity and durability are the principal characteristics of the works under notice. In some measure, the nature of the foundations, which is very bad, necessitates a more massive style of construction than might otherwise be required, but, in addition, there is very little doubt that the magnitude and importance of the undertaking has had its proper weight with the engineer of the company, Mr. Evans, M.I.C.E., from whose designs emanate the whole of the works. A cordial vote of thanks was proposed by the President and unanimously accorded to the engineers and contractors, who, by their courtesy, assistance, and hospitality, had rendered the visit valuable to the professional man, instructive to the young members of the society, and agreeable to all.

THE MINERAL RESOURCES OF THE WEST ROCKY MOUNTAINS.

A FEW years since, Congress voted a sum of money which was to be expended in collecting reliable statistics of the mineral resources of the United States. A special appointment was conferred upon Mr. J. Ross Browne, under which he performed this service in the states and territories west of the Rocky Mountains. To Mr. James W. Taylor was assigned the duty of collecting similar statistics on the east of the Rocky Mountains. Mr. Browne issued two reports upon the subject, and then vacated the position. The United States Government, seeing the importance of continuing Mr. Browne's labours, appointed, in April, 1868, Mr. Rossiter W. Raymond a special commissioner for the collection of mining statistics in the western division, which had been the scene of Mr. Browne's labours. On receiving the appointment, Mr. Raymond found that there was but a small remnant of previous appropriations left in the treasury. However, with the spirit of a man who meant to do his work, and not merely to spend the funds placed at his disposal, he decided not to wait for a further appropriation, but to start with what there was at his command. By the general courtesy of railroad, steamboat, stage, and express companies, Mr. Raymond was able to economize the little he had, and to complete, during the summer of 1868, a journey of some 13,000 miles. The result of this journey is now before us in the form of a very interesting as well as useful report, which has been printed at Washington, and, by the courtesy of the United States Government, we have just received a copy. In the preparation of this volume of some 260 pages, Mr. Raymond has personally worked very hard, as the lack of means placed it out of his power to engage competent assistants, or even to employ a clerk for tabulating and calculating statistics. Under these exceptional circumstances, the report is very creditable; it is necessarily somewhat partial, but it is accurate, and contains a fund of information of value both to the Government and people of the United States.

The subjects to which Mr. Raymond was instructed to give his special attention were, first, the different processes of treating the ores, their chemical combinations, and the system demonstrated by practical experience to be the most successful. Next, the relative merits of the various inventions, machines, and mechanical contrivances, in use or proposed, for the reduction of the precious metals, and for all other matters connected with mining and metallurgy. Thirdly, the special needs of the great mining interest, how it can be encouraged and rendered most productive; how far individual enterprise should be left untrammelled by legislative action; and to what extent, and in what instances, Government aid might with propriety be afforded to facilitate the development of the mines, and thus arrest the annual decrease in the production of bullion. Finally, Mr. Raymond was to note the experience of other countries resulting from the establishment of national institutions for the education of miners, and to point out how far the prevalent European systems were applicable to the people of America, and appropriate under their government. The report is divided into two parts, the first of which contains such observations on the present condition of American mining industry as Mr. Raymond could collect, and the second discusses, at considerable length, the subjects involved in the relation of the government to that industry. The subject of methods and processes of mining and reductions have been postponed, and will form the subject of a further report.

Under the head of relations of Government to mining, Mr. Raymond gives us, first, a history of mining and mining laws as practised among the ancients, as well as in the Middle Ages. We then have, successively, epitomes of the Spanish mining law, the modern German codes, the code of France, the mining laws of Switzerland and of England, mining regulations in Australia, and the mining laws of Canada. After comparing these various codes together, and stating the American mining laws, Mr. Raymond recommends various amendments in the latter by which the various conflicting customs which now obtain shall be merged in one general principle, and by which all rights and titles should be specifically determined, which they do not appear to be at present. The necessity of mining education is fully recognized by Mr. Raymond, who recommends the appointment of a Government commissioner, a bureau, and a national school. The latter means of imparting information is fully discussed, and particulars are given of the Frieburg School of Mines, the Paris School of Mines, the Prussian Royal Schools of Mines at Berlin, and the School of Mines at Clausthal, Prussia. The history of the world proves that all nations eminent for profitable and permanent mining have employed two agencies for success—a national mining code, and a national mining school. These, says Mr. Raymond, the United States must have, and must have at once, if any real good is to be effected thereby.

The present report is illustrated with several woodcuts of underground workings, th mines selected being such as were capable of being represented by simple profiles. These profiles are taken on the plane of the vein (local irregularities being disregarded) and show the quantity of ground already excavated and the quantity remaining either unopened or so far opened as to come under the head of reserves, which includes the portions of a vein where stoping or extracting ore may at once be commenced, the preparatory shafting and drifting (or opening of galleries) being complete. The Eureka mine of Amador county, California, and the Social and Steptoe mine of Egan canon, Nevada, are examples in which the amount of reserves or ground opened in advance is very large. Many of the Grass Valley mines are characterized by the same peculiarity, as the sketches show; and in this case the prudence of the management is worthy of high praise, since the Grass Valley veins are narrow and hard, and the maintenance of large reserves is a matter of difficulty and expense. Many mines of celebrity and interest are not represented by sketches, because (as is the case with the Comstock mines) they could not be shown in simple profile, or because the expense of making the necessary measurements and drawings (in cases where none were accessible) was greater than Mr. Raymond felt justified in assuming; or, finally, because the character of the underground workings was so irregular and unskilful as to confer no credit upon the owners, and convey no instruction to the public.

From the report before us we find that the bullion product of the last year was more difficult to be estimated than that of almost any preceding one. The bullion tax having been abolished, the best source of knowledge on the subject was taken away. Messrs. Wells, Fargo, and Co.'s express returns, which have hitherto been an important aid in estimating the movement, and thus the product, of bullion on the Pacific coast, have lost their comprehensive character by the establishment of a rival express company (the Union Pacific), the amount of the business of which is said to be considerable, but which had not been, at the date of the report, authoritatively stated. From the best authorities and such official returns as could be collected, Mr. Raymond estimates the product of the whole country as follows:—

	dollars.
California	22,000,000
Nevada	14,000,000
Montana	15,000,000
Idaho	7,000,000
Washington and Oregon	4,000,000
Arizona	500,000
New Mexico	250,000
Colorado and Wyoming	3,250,000
All other sources.	1,000,000
	67,000,000

This is a decrease of 8,000,000 dollars from the product of 1867, which showed a falling off of some 8,000,000 dollars as compared with that of the year before. Montana, Idaho, and Colorado manifest a satisfactory improvement; but there is a decrease of 5,000,000 dollars from California, and 6,000,000 dollars from Nevada, the latter being due to the exhaustion of many of the Comstock ore-bodies. It is an instructive fact that the greater part of the product from deep mining was furnished by the same mines in 1868 as in 1867, and the year before, indicating that a more general adoption of systematic and economical methods would result in greater stability of production. The yield from placer mining must be expected to decrease, and its place must be supplied by the cement and quartz mines.

The causes of the decrease in American production of bullion are enumerated as follows:—1. The exhaustion of many surface deposits. 2. The reaction following upon a period of excited speculation, and the collapse of numerous dishonest schemes. 3. The increasing and novel difficulties attendant upon the management of deep mines, and the reduction of refractory ores. 4. The lack of communications, capital, and knowledge, such as are required for the creation of enterprises based on the extraction and reduction of ores of low grade in large quantity—the only stable form of mining; and, 5. The vexatious and ruinous litigation which waits upon mining on the public domain, and which is most troublesome and expensive where mining is, in other respects, most profitable—thus operating to destroy those

enterprises which have overcome other difficulties—all these may be summed up in one sentence. Mining in the States has been found, in too many instances, to be unprofitable; and the individuals who have lost money have retired from the business. It certainly is not the duty of the government to give bounties to bolster up mining industry, if that industry is, by the nature of the case, an unprofitable one. Yet it cannot be denied that the decrease of the product of gold and silver in America is a matter which particularly concerns the government at this time; and it may well be inquired whether the causes of it are remediable. Mr. Raymond believes that time will remove many of them, and that the action of the government, based upon a just appreciation of its relations to the mining industry, will do away with the rest.

Concerning the extent of the mineral resources in the States, the half has never been told; but those resources are but one factor, which must be joined with labour and intelligence to make the product wealth. When the industry of mining in these rich fields is based upon a foundation of universal law, and shaped by the hand of educated skill, then, says Mr. Raymond, "we may expect it to become a stately and enduring edifice, not a mere tent, pitched to-day and folded to-morrow. This industry has been the pioneer in our far western territory. It has founded states, attracted population, enlarged the boundaries of civilization; and it has done this great work in a lawless and careless way, without much regard to the future. All other parts of society springing from it are gradually becoming systematized and consolidated, but the primitive industry remains in its primitive condition. Establishing everything else, it has not established itself. I believe that with the extension of the government surveys over the public domain, and the reduction of its vast area to order and law, the consolidation and definite adjustment of the mining interests will become imperatively necessary; and inasmuch as mining outruns all other activities in our new territories, and needs more than any other the aid of judicious legislation, I believe it should receive immediate attention." We believe that the views and suggestions contained in the report, and which are an enlargement of the summary contained in the foregoing extract, based, as they are, upon Mr. Raymond's personal observation, experience, and study, will prove of value to America if acted upon by the government with promptitude. A timely support to her mining industry will stimulate the settlement of her vast territory, and the organization of stable communities upon it, and secure the future material progress of the country.

NOTES ON RECENT DISCOVERIES IN SCIENCE AND THEIR PRACTICAL APPLICATIONS.

ELECTRIC ALARUMS FOR VARIATIONS OF TEMPERATURE—EFFECT OF AIR IN DIMINISHING THE ILLUMINATING POWER OF COAL GAS—EXTRACTION OF BENZOLE FROM GAS—NEW USES FOR OLD SHOES.

It is in many cases—notably in some stoving operations and in the management of hot-houses—very desirable to have warning when the temperature rises above or falls below a certain heat. A rise of temperature is easily made known by what may be called a maximum thermometer alarum, a well-known instrument, which is made by carrying one platinum wire in connection with a battery and bell into the bulb of a mercurial thermometer, and another wire down the tube to the degree it is not desired to exceed. When the mercury rises to this point the circuit is completed and notice is given by the ringing of the bell. But an instrument to give warning of a fall of temperature is new to us, and we borrow a description of it from the account of MM. Besson and Kneider, who have contrived it. It consists of a spirit thermometer, the bulb of which is placed above, and the tube curved in a U shape. A platinum wire is carried into the bulb and down to the degree of heat it is wished to notify. Below this minimum the curvature is filled with mercury, which is in free communication with a second platinum wire. As the alcohol contracts with the cold the mercury will, of course, rise, and reaching the first platinum wire complete the circuit and give the warning. One bell and the same battery will serve for the two thermometers; but it will be necessary to interpose a commutator to ascertain through which circuit the current is passing and whether a rise or fall is indicated when the bell is rung.

The effect of atmospheric air in diminishing the illuminating power of gas when the two are mixed together has recently been investigated by two very able experimenters, Dr. Silliman and Professor Wurtz. Their results, which differ somewhat from those of previous experimenters, may be summed up in a few words. When gas is mixed with anything less than five per cent. of air the loss of illuminating power is a little over one-tenth of a candle for every one per cent. of air. With more than five per cent. and up to twelve per cent., the loss rises to half a candle for every one per cent. of air. Above twelve and up to twenty-five per cent., however, the loss of illuminating power is but four-tenths of a candle for the one per cent. of air. Twelve per cent. of air, they tell us, destroys forty per cent. of illuminating power. The experiments of MM. Audouin and Bèrard, made for the municipality of Paris, show a higher rate of loss than this, while those of Schultz are to a certain extent in accordance. He gives, as a general statement of results, a loss of half a candle for every one per cent. of air. The last-named experimenter, however, made the observation that with very rich cannel gas no loss of illuminating power, but rather an increase, took place up to twelve per cent. of air. If this be established the information will be very useful to cannel gas makers.

The demand for benzole has created a general desire to increase the yield. At present, the only available source is coal tar. But it is known that much benzole vapour remains uncondensed and passes on with the gas, and experiments, we read, have been made with the idea of securing this quantity. In Germany, it would seem, they have tried scrubbing the raw gas with the heavier tar oils with much success. The benzole is said to be taken out of the gas by this means, and is afterwards separated as usual by fractional distillation. The results are vaguely stated, and we can give no opinion on the process which, does not look to us promising, although it is said to yield immense quantities of benzole. The experiments of M. Berthelot point to a not distant day in which the heavier oils will be easily transformed into benzole in any quantity. He has already succeeded in effecting the transformation on a small scale, and his most recent researches seem to show that it may be done on a manufacturing scale. It is hardly necessary to say that if all benzole vapour be removed from gas, the illuminating power will be very considerably diminished.

Old shoes are not altogether wasted, but they have been put to a new use by M. Guyot. He cuts them up into thin shreds, and treats these with chloride of sulphur. Under this treatment, the shreds at first swell up and then become friable and brittle When this stage is arrived at, they are washed, dried, and ground to a fine powder, which we are told is of a grey-rose colour. This is mixed with some gummy or glutinous matter, and the mass is pressed into moulds to form combs, buttons, knife-handles, and such like articles. During the treatment with chloride of sulphur, it must be mentioned that the vapour of hydrochloric acid is given off, which on hygienic grounds requires to be condensed. Then when the shreds arrive at the brittle state, it is necessary to remove the excess of chloride of sulphur, and we imagine sulphur also. This is done by washing with sulphide of carbon, the recovery of which demands precaution. Taking all things into consideration, we doubt whether M. Guyot can make much profit by his process for converting old shoes into combs, although, by putting on the head what was once on the feet, he may, in one sense, be said to make both ends meet.

PROCEEDINGS OF THE BRITISH ASSOCIATION.

SECTION A.—MATHEMATICAL AND PHYSICAL SCIENCE.

SELF-REGISTERING HYGROMETER.

BY MR. E. VIVIAN.

MR. E. VIVIAN, of Torquay, read a paper on his new self-registering hygrometer. At a former meeting, he exhibited a self-registering instrument on the cumulative principle of recording mean values of the differences between wet and dry bulb thermometers, and a self-registering maximum and minimum hygrometer. He now produced an improved form of the former instrument, with a series of curves showing the comparative results of Leslie's hygrometer, his maximum and minimum differential, and his mean self-registering, which he now offered as the standard. He gave the uses to which it might be put. He had used it in recording the aggregate differences of solar heat of the sun and shade, the duration of rain, and the amount of nocturnal radiations, and many other similar purposes. He now proposed to apply it to recording the actual mean temperature, which would be an important feature if it could be worked out, and he believed it could, and also to the anemometer. He gave a full description of the instrument and its mode of working.

Mr. Symons thought the instrument valuable, and said he should like to see such a one at every watering place. He referred to the differences in the meteorological instruments used, and their position in different parts of the country, and said he should like to see every town furnished with a good set of instruments, placed in suitable and open positions.

Mr. Vivian said he should be happy to present one of his instruments to any watering-place that would like to possess it.

REFLECTION OF HEAT.

BY PROFESSOR MAGNUS.

IN this paper, Professor Gustav Magnus made known a curious discovery of his own that fluor spar has the property of reflecting, very largely, the dark invisible rays emitted by rock salt.

Dr. Balfour Stewart then called attention to the fact that there is much evidence tending to prove that the heat rays from rock salt are of very great wave length, belonging almost to one of the extremities of the spectrum.

REPORT ON GOVERNMENT AID TO SCIENCE.

BY LIEUTENANT-COLONEL STRANGE.

IN introducing the report, Lieutenant-Colonel Strange alluded to the proceedings last year at Norwich, which resulted in the formation of a committee to determine whether there is at present adequate provision in Great Britain for the vigorous prosecution of scientific research. The committee had, he said, come unanimously to the conclusion that science had not adequate means for its vigorous prosecution. He, personally, did not hold the very general opinion that it was a hopeless step to ask the present Chancellor of the Exchequer for Government aid. He then read the following report of a committee appointed by the British Association for the Advancement of Science at Norwich for the purpose of inquiring into, and of reporting to, the British Association the opinion at which they may arrive concerning the following questions:—I. Does there exist in the United Kingdom of Great Britain and Ireland sufficient provision for the vigorous prosecution of physical research? II. If not, what further provision is needed? and what measures should be taken to secure it?

Your committee, having sought the counsel of many of the most eminent men of science of the United Kingdom upon these questions, so far as it was found practicable to do so, and having carefully deliberated thereon, have arrived at the following conclusions:—I. That the provision now existing in the United Kingdom of Great Britain and Ireland is far from sufficient for the vigorous prosecution of physical research. II. It is universally admitted that scientific investigation is productive of enormous advantages to the community at large; but these advantages cannot be duly reaped without largely extending and systematising physical research. Though of opinion that greatly increased facilities are undoubtedly required, your committee do not consider it expedient that they should attempt to define categorically how these facilities should be provided, for the following reason:—Any scheme of scientific extension should be based on a full

and accurate knowledge of the amount of aid now given to science, of the sources from which that aid is derived, and of the functions performed by individuals and institutions receiving such aid. Your committee have found it impossible, with the means and powers at their command, to acquire this knowledge. A formal inquiry, including the inspection of records to which your committee have not access, and the examination of witnesses whom they are not empowered to summon, alone can elicit the information that is required; and, as the whole question of the relation of the State to science, at present in a very unsettled and unsatisfactory position, is involved, they urge that a Royal Commission alone is competent to deal with the subject. Your committee hold that this inquiry is of a character sufficiently important to the nation, and sufficiently wide in its scope, to demand the use of the most ample and most powerful machinery that can be brought to bear upon it. Your committee therefore submit, as the substance of their report, the recommendation that the full influence of the British Association for the Advancement of Science should at once be exerted to obtain the appointment of a Royal Commission, to consider—1. The character and value of existing institutions and facilities for scientific investigations, and the amount of time and money devoted to such purposes. 2. What modifications or augmentations of the means and facilities that are at present available for the maintenance and extension of science are requisite; and 3. In what manner these can be best applied.

On the Determination of the Real Amount of Evaporation from the Surface of Water.

BY MESSRS. G. J. SYMONS AND ROGERS FIELD.

The authors begin by pointing out the very inconsistent statements of even able meteorologists, and quote returns in proof of this. Thus for the same year, one observer gives the evaporation as 11in., and another observer gives it as 48in. They then quote the meteorological essays of the late Professor Daniell, to show how strongly he condemned the existing forms of evaporations, and then pass on to criticise the mode of computing the quantity of evaporation from hygrometric observations, proposed by Professor Daniell as a substitute for quantitative measurement. After a few words upon what the authors believe to be the great source of error in all existing forms of evaporation, namely, undue heating of the water experimented upon, they proceed to describe a series of experiments at Dijon and other places on the canal of Burgundy, in which the evaporation was measured in large tanks, and found to be only about half what was generally assumed to be the amount. Reference was then made to a very ingenious and accurate instrument for measuring the depth of water used by the authors; this apparatus—called a "Hook Gauge"—being exhibited and tried by members of the committee. Large drawings illustrated the apparatus Messrs. Symons and Field have hitherto used, and a number of tables were "taken as read." The authors epitomised the results of their experiments, showing what very erroneous measurements, even to the extent of 10 per cent. of error, were yielded by the best of ordinary evaporators, and concluded with a strong plea for further investigation by quoting the words of M. Valles, the French engineer, who first called attention to the great inconsistency of existing experiments:—"We do not understand how, in a country like ours, and with reference to one of the most important hydraulic data, we can rest content with only knowing that the numerical value of this datum lies between two limits, one of which is double the other."

The Refractive Energies of Metals.

BY DR. G. H. GLADSTONE, F.R.S.

This was a short instructive address on the relation between the refractive energies and the combining proportions of the metals. He pointed out that in most cases, but not all, the less the combining proportion of the metal the greater is the refractive energy. As metals are opaque and do not in the simple state refract light, in his experiments he had to use their salts in solution. The rule just mentioned does not hold at all with nonmetallic elements, and proves most accurate with those metals which form good definite salts, such as magnesium, iron, and zinc.

SECTION B.—CHEMICAL SCIENCE.

On the Measurement of Gases as a Branch of Volumetric Analysis.

BY DR. W. J. RUSSELL.

The author of this interesting paper stated that at present the measurement of the amount of gas given off during a reaction has been but little, if at all, used as a means of quantitative analysis. This, he observed, has arisen from the want of some simple and easy way of collecting the gas evolved. In a paper read before the Chemical Society last year he showed how carbonates might with very considerable accuracy be estimated in this way; and since then he has used the same method of determining the atomic of weights of nickel and cobalt. This form of volumetric analysis is of more general application than might at first sight appear probable, and will, it is believed, in certain cases be found of considerable importance. Having no standard solutions to prepare and keep in order is an obvious advantage; the gas apparatus, once in order, is then always ready for any kind of analysis in which gas is evolved; the reactions made use of, as a rule, take place rapidly, and the volume of gas, as far as the measurement of it is concerned, can be effected with very considerable accuracy. The amount of material used is generally very small, and the whole analysis occupies but a very short time, and can be very easily performed. The form of apparatus used for collecting and measuring gas has been already described in the "Journal of the Chemical Society" for August of last year. The lecturer gave some very interesting illustrations of the method he adopted in the analysis, and concluded by showing the results obtained by his method of volumetric analysis.

On Jargonia.

BY MR. SORBY.

The substances known as zirconia and jargonia were supposed to be identical. Recent experiments have shown them to be different, especially in colour, which is probably a characteristic peculiarity. The colour was thought due to the existence of iron, but subsequent experiments may show the colour is due to some other substances.

On the Amount of Soluble and Insoluble Phosphates in Seeds.

BY PROFESSOR GRACE CALVERT.

The Professor said that the results of various experiments he had made was that 100 parts of cotton fibre yield, when repeatedly washed with water, a quantity of acid phosphate of magnesia. Both husks and seeds also yield certain proportions, and these results show that the phosphates exist in much larger quantity in the seed than in the other parts of the pod. Experiments upon wheat flour of various kinds showed that whilst the flour contains only a trace of phosphates, especially soluble ones, the bran contains a large quantity. These facts tend to prove that the phosphates and the mineral matters contained in wheat are not combined with the organic matter, but are in a free condition. Other investigations go to prove that, although habit and pride have gradually led us to prefer white bread to brown, yet this is an error when we consider the nutritious properties of wheat, especially as food for children, phosphates being essential for the formation of bone and blood.

On the Economic Distillation of Gas from Cannel Coal.

BY DR. MACADAM.

The experimental observations which form the basis of this communication were undertaken for the purpose of determining the quantity and quality of gas obtained by the distillation of certain mixture of coals, as contrasted with the coals taken separately. Some samples of coals were selected for examination, and these were distilled in a small gaswork connected with a fully equipped apparatus. Each of the coals was examined separately, and thereafter the various coals were mixed in the proportions indicated by the separate analyses as likely to yield 10,500 cubic feet of gas, with 30 candle power, for every 5 cubic feet of gas consumed during a single hour. The mixed coals were in each trial placed in the same retort heated to a uniform temperature, and the experimental results demonstrated that where coals of different gas-producing power are heated in the same retort they yield a gas of superior illuminating power to that obtained from a mixture of the gases evolved from the same coals heated in the same proportions in separate retorts. Thus, two coals, which heated separately would yield from one ton, 10,806 cubic feet of gas of 30·09 candle power, when heated together give 10,714 cubic feet of gas, of 32·27 candle power; three coals were then used with similar differential results. Nine trials of mixed coals showed that the average increase of the illuminating power of the gas evolved from the mixtures of coals heated together in the same retort, as contrasted with the gas yielded by the same coals distilled in separate retorts, was 7·57 per cent., or one-thirteenth more of illuminating power.

On Some New Substances Extracted from the Walnut.

BY DR. T. L. PHIPSON.

Between the shell and the kernel of the walnut there exists a thin membrane called the episperm which closely envelopes the cotyledons, and is composed here, as in most other fruits, of a double membrane, the inner one being very thin, quite white, translucid, and perfectly devoid of taste, while the external one is much coarser in structure, more or less coloured, has a very bitter disagreeable taste, and contains certain substances which form the subject of this paper. From this membrane Dr. Phipson had extracted a substance which he called *nucitannic acid*, the most remarkable property of which is that, when boiled with dilute hydrochloric acid, it splits up into glucose and another new substance called *rothic acid*.

On the Solubility of Lead and Copper in Pure and Impure Water.

BY DR. T. L. PHIPSON.

Within the last few years a number of samples of water have been sent to me for analysis, said Dr. Phipson, with the question, "Will it attack lead pipes?" Having, at various intervals, tested a large number of specimens of commercial lead used for domestic and other purposes, the result of my experiments is that lead, copper, and perhaps zinc, are metals which can be dissolved in water at ordinary temperature, and in presence of air when submitted to friction, and that the water need not be so pure as the Surrey spring water in order to exert this solvent action.

Utilisation of Sewage.

BY DR. PAUL.

Dr. Paul, in his paper on the treatment and utilisation of sewage, alluded first to the necessity of adopting better regulations in large cities and towns for that purpose. He very justly insisted on the necessity of pure air and water to ensure the health of the vast population of this country. In thinly populated towns no great difficulty would be experienced in devising simple measures sufficient to meet all requirements, and the mode of effecting the object in view would of course be a matter to be determined and carried out by the individual residents of a place. As the magnitude of towns increased, the difficulty of dealing with the question became greater, and the offensive consequences of accumulation near dwellings became more sensible, and hence the subject became more and more a matter to be dealt with by the local authorities. The lecturer showed conclusively the deleterious effects of some gases by the pollution of water, and from refuse allowed to accumulate in a state of putrefaction or decay near dwellings. Opinions vary as to the precise mode this baneful influence is exercised, whether by the evolution of deleterious gases, by the development of those minute organisms which are now considered very generally to be the media of infection, or in all these ways conjointly; but there is no longer any doubt or difference of opinion as to the general truth that, in regard to the mode of dealing with excretal refuse, the sanitary point of view is far more important than any other.

Extraction of Ammonia from Gas Liquor.

BY MR. F. BRAY.

A few years ago the refuse from coal gas works was perfectly useless, but the progress of science has discovered valuable uses for gas liquor. From coal tar not only now are obtained naphtha, benzole, carbolic acid, but various brilliant dyes and colours. The paper fully described the apparatus for extracting the ammonia by the author's plan; and the advantages effected are economy in labour, time, and occupation, of plant, together with the facility of extracting the whole of the ammonia in a pure condition. A manufactory previously consuming 10,000 gallons of gas liquor per week may now utilise 24,100 gallons, and at about half the expense of fuel that was formerly incurred.

On the Supposed Action of Light on Combustion.

BY MR. C. TOMLINSON.

The popular idea that "light puts out the fire" is so fixed that probably no conclusions drawn from

actual experiment are likely to disturb it, especially if they be adverse to the notion. It is a matter of daily experience, as people say, that if a fire is nearly out in a well-lighted room, you have only to draw down the blinds in order to revive the fire. Experiments on the subject are not easily made, in consequence of the many disturbing causes; but, from some experiments found in an old volume of the "Annals of Philosophy," made upon coloured tapers, the conclusion arrived at was that the solar rays, in proportion to their intensity, have the power of retarding to a considerable extent the process of combustion, but this conclusion is open to objection—from a series of experiments on candles of different sizes and weights in dark chambers and day and sunlight. It was found that the increase of temperature led to increased consumption of material and *vice versa*, and the whole result may be stated that, in any case, the difference is so small that it may be referred to accidental circumstances, such as temperature and material—the final conclusion being that the direct light of the sun, or the diffused light of day, has no action on the rate of burning, or in retarding the combustion of an ordinary candle.

SECTION C.—GEOLOGY.

KENT'S CAVERN.

BY MR. PENGELLY.

MR. PENGELLY read the fifth report of the committee on the exploration of Kent's Cavern. He said that beneath the floor of the vestibule was a layer of black soil, 6in. to 9in. deep, which had yielded 366 flint implements, bones and teeth of recent and extinct animals, charcoal, flint cones, &c. It had been objected that people could never have lived in the caverns, because smoke would have suffocated them. An experiment which had been tried, in burning six faggots of wood, showed the fallacy of the objection. In the exploration of the cavern, a daily journal had been kept, and every circumstance was noted down. 3,948 boxes of fossil bones had been found, and these Professor Boyd Dawkins undertook to examine for the purpose of determining the species to which they belonged. Among other objects, a bone needle had been found in the black band beneath the stalagmitic floor. The eye was capable of carrying a thread the thickness of thin twine. A bone harpoon or fish-spear, forked on one side only, had been met with. Other undoubted evidences of early human art had been found. During the years 1868-9, Mr. Everitt, who is engaged by the Rajah of Sarawak to explore the cave of Borneo, visited Kent's Hole for the purpose of familiarising himself with the mode of operation. Mr. Pengelly then detailed the various layers underlying the stalagmitic floor, in which he was aided by a series of large diagrams. The cave earth, or floor underneath the stalagmite, was full of flint implements, teeth of the mammoth, bear, hyena, &c., and gnawed and split bones. Inscriptions dated 1688 had been found on the stalagmitic walls of that part of the cavern known as the crypt. The deduction drawn by Mr. Pengelly was that this period of time, although the dripping of water was very copious, had been insufficient to coat over and obliterate the writing. This gives some idea of the immense age of the stalagmite floor, and of the time occupied in its formation. Beneath the earth was a breccia, and up to last year not the slightest traces of man had been found. This year, however, a flint flake was met with, thus carrying the antiquity of man further back. A monthly report had been sent up to Sir Charles Lyell. In some places, the stalagmitic floor was as much as 12ft. thick. Associated with the flakes were the remains of the cave lion, the cave bear, the mammoth, &c. In fact, this was the most important anthropological relic which the cavern had yielded. Mr. John Evans, F.R.S., had seen the flint flake, and had declared it to be of undoubtedly human workmanship.

Professor Boyd Dawkins read a few notes on the mammalian remains mentioned by Mr. Pengelly. He showed that the various strata of the floor of the cavern contained remains of animals of different epochs, from the post-glacial upwards. During the time the black or upper band was being formed, a race of cannibals inhabited the cavern. The older deposits contained remains of the glutton, a species of hare larger than the existing type, the beaver, &c. Mr. Dawkins concluded by remarking on the vast antiquity of the human race as indicated by the facts mentioned in the report.

ON THE TRAPPEAN CONGLOMERATES OF MIDDLETOWN HILL.

BY MR. GEORGE MAW.

THIS was a description of the contemporaneous traps of Lower Silurian age in the ridge known as the Middletown Hill, running parallel with the Breidden, on the borders of Shropshire and Montgomeryshire. Especial reference was made to the great beds of bouldered trap, consisting of boulders of felstone, of compact texture, imbedded in a matrix of felstone tuff. The nodules occupy about half the mass of the conglomerate, and are unaccompanied by pebbles of any other rock. They vary from the size of a walnut to rounded masses weighing more than a hundredweight. Sir R. Murchison's description of these beds was referred to, and the author took exception to the term concretionary trap, employed in the Silurian system, as he considered the rounded outline of the boulders was unquestionably due to mechanical causes. The interbedded traps, bounded on either side by the Lower Llandeils Flags, are of a collective thickness of about 780ft., including two beds of the bouldered felstone, 114ft. and 140ft. thick, alternating with two beds of a whitish green felspathic breccia, 210ft. thick and 315ft. The line of separation between the breccia beds and the beds of boulder trap is remarkably sudden, and no graduation of character occurred between them. The breccia is worked for hard felspar, used for pottery purposes, and contains small nests of steatite. The bouldered condition of the felstone beds was considered due to their partial breaking up on being erupted under water, the soft matrix of felspathic tuff being the portion more intimately divided, and the compact boulder fragments that had resisted watery disintegration. The sudden alternation in Middletown Hill of eruptive beds of very dissimilar character was noticed. They seem all to have been emitted in immediate succession, as, although overlaid and underlaid by sedimentary rocks, there is no evidence of the interstratification of sedimentary beds. The author, in conclusion, pointed out the close geographical association with these bedded traps of the much later porphyritic greenstone of the Breidden Hills, which, it was suggested, might have been emitted from the same point of eruption; and the local association of the intrusive greenstones with the Lower Silurian interbedded felstones was noticed as being very general in North Wales.

Specimens of the conglomerates were exhibited, and the President of the Section, Professor Harkness, said he had no doubt they were of mechanical origin. In this view also, Mr. Maw was borne out by Mr. Boyd Dawkins, Mr. Moore, and others, although exception was taken to it by Mr. Edward Hull, who thought the rounded pebbles might be due to weathering, as spheroidal weathering was characteristic of felspathic rocks.

Mr. Godwin-Austen said one of the chief benefits of the Association meetings was that they showed how much could be said on both sides. He referred to recent volcanic eruptions as illustrating how the beds mentioned might be deposited.

A short communication was made by Mr. W. Carruthers on reptilian eggs from secondary strata. Some of the eggs were *Chelonian*, or turtle, in their character. Many of them had all the appearance of fruit. They had a peculiarly glossy appearance, and were very thin. Mr. Carruthers went into some detail on the origin of small shakeneides found in coal shale, and explained how they had been formed by gas or air.

THE EXTINCTION OF THE MAMMOTH.

BY MR. H. H. HOWORTH.

IN this interesting paper the various historical notices in old authors of the Mammoth remains in Siberia and elsewhere, were well condensed. The usual idea was that the mammoth was a sort of huge mole, which rarely came to the surface. This was the way their vast remains were accounted for. Mr. Howorth did not think the extinction of the mammoth ought to be ascribed to the men of the early stone age.

Professor Phillips and Professor Boyd Dawkins made some remarks on the paper, the former dwelling at some length upon the more popular geological notions of the former conditions of northern geography, and the latter observing that Mr. Howorth had misunderstood him. He had never said that the extinction of the mammoth in Siberia was owing to his being hunted down; but he had stated that in England and Western Europe generally, there was no doubt that the mammoth had become extinct by the hand of man.

Mr. Howorth briefly replied, stating that he still differed from Mr. Dawkins as to the extinction of the animals mentioned. He thought that different races of man had become extinct along with the animals.

ON THE FOSSILS OF KILTORCAN.

BY MR. BAILEY.

THIS was a report on the fossils of Kiltorcan, county Kilkenny, of the Geological Survey. The fossils in question are those of the Old Red Sandstone. Some of them were exhibited, and the appearance of the fine fronds of ferns, two feet across, extending over the surface of the greenish sandstone, was very striking. Some of the large fluted stems of another fossil plant, six inches in diameter, were also shown. The most important additions made by the researches of Mr. Bailey were among the fossil crustacea, belonging to the family *Eurypteridæ*, many of the forms being new to palæontology. Fossil fish had also been met with, allied to the genera *Dendrodus*, &c.

In the discussion which followed, the President remarked that the systematic excavations which had been made at Kiltorcan had been of considerable importance to Irish geology. Sir Philip Egerton confirmed the fish relationship of many of the triangular scales.

Mr. Carwithers said that the discovery of the large fossil ferns was very valuable. The finding of the *Sagenaria* in fructification was rare, and this specimen in its root, leaves, and fruit, was a valuable contribution to fossil botany.

Mr. Henry Woodward said the association of fossil ferns with crustacea was unique. He hoped that Mr. Bailey would be aided by a further grant from the British Association, in order that he might continue his researches in those very interesting beds. The crustacean remains were of a most important character, and he thought they might expect to find innumerable new forms. In the present controversy, as to the fresh-water or marine origin of the Old Red Sandstone, such researches would be of immense importance.

Mr. Charles Moore, F.G.S., then made a communication relative to a specimen of *Teleosaurus* from the Upper Lias. He said he had discovered shells (*Leptæna*) in the Middle Lias, which had been thought peculiar to the Palæozoic rocks. Above these was a bed rich in nodules, and these nodules when broken open were seen to be full of the bones and other remains of *Teleosaurus*.

SECTION D.—BIOLOGY.

MAN AND THE ANIMALS.

BY ARCHDEACON FREEMAN.

THIS paper involved a counter-theory to Mr. Darwin's as to the origin of species. The author referred to the similarities existing between man and animals, and triumphantly asked how were those similarities of appearance to be accounted for but by such a theory? The answer might be found in a counter-theory. Darwin's theory, in answer to his question, was that there was unity of type, explained by unity of descent—he supposed that all animals had graduated from each other. Why not accept the teachings of the biblical record on this point; and could not a foundation be found for the similarity in animals in the biblical account of creation? At that time after the fall of man, certain mysterious creatures appeared, and appeared, too, externally to the proper cosmos or creation, and which were placed at the entrance to Paradise to bar man from the happiness which he had forfeited. By the description of those creatures, they appeared to unite in themselves the characteristics of four of the noblest of animals, man—he lion, the ox, and the eagle. Did not the existence of those mysterious creatures seem to suggest that the creation was a modification of those mysterious creatures, a doctrine which was largely believed by Plato? Here they had an answer to Darwin's theory, and an answer which they had never seen put forward at present. They would meet his question, in fact, by the answer that there was another answer to his question than that which had been given. The answer to Darwin was that a nobler page was given the animals bearing a noble relation, but not relationship to man, and that this view would be found consistent with the phenomena noticed by Darwin.

THE DIFFICULTIES OF DARWINISM.

BY THE REV. F. O. MORRIS.

THIS paper commenced by describing Darwin' argument as a *non sequitur*—a mere assumption that because there was similarity in different

animals, therefore there must be continuity. The writer also had collected a variety of instances of fixity of species, under circumstances in which a change might have been expected where no change had taken place, and said that there was abundant proof, both in the animal and in the vegetable world, that no change from one species to another had ever or would ever take place. The writer pointed to the well-known difficulty experienced by those who wished to preserve either plants or animals of some artificial type in preventing a return to the original. When he found small birds of a peculiar kind on an island, Darwin's theory was that they had come from the main land, and had become changed in consequence of the altered conditions. That theory, however, gave no *cui bono* for such an argument—it was merely an assumption. Moreover, had the birds, when they came to the island, found it suitable, they need not have changed, and if unsuitable why did they stay there? The proceedings in regard to acclimatisation during the last few years had almost served to upset the theory of a change from one species to another on account of altered conditions, as salmon were naturalised in waters very distant from their original home, and under vastly changed conditions, without altering them, and in many directions in the animal kingdom they found animals subjected to great changes, and submitting to them without making any change in the race, or individuals of the race.

PHILOSOPHICAL OBJECTIONS TO DARWINISM OR EVOLUTIONISM.

BY THE REV. J. M'CANN, D.D.

THE author of this paper complained that scientific men did not allow the subject to be treated philosophically. He also examined some of Professor Huxley's statements concerning the origin of life, and entered upon an elaborate argument concerning consciousness and the sufficiency of the evidence of the senses. He handled some of Professor Huxley's arguments and theories very severely, and contended that they led necessarily to materialism and fatalism, although he wished to speak with feelings of brotherly love of the Professor himself.

At the close of the reading of these papers, which bore upon one and the same subject, there were loud calls for Professor Huxley, who stepped at once upon the platform at the request of the President, who characterised the papers as having had nothing to do certainly with the Darwinian hypothesis. Professor Huxley said it was painful to men of science, who were working on those great and serious questions with all the sense of responsibility which the grave nature of the task created, to have brought under their notice year after year—and it was now ten years since the Darwinian discussion first commenced—the same arguments, which had been answered and counteranswered again and again, and the answers to which might be found scattered broadcast. As he heard paper after paper of that kind read, it seemed to him to be one of the strongest arguments against the doctrine of progress, for they were no further than they were ten years ago. The last paper which had been read, and which was fresh in their minds, should receive some of his attention. He, like Dr. M'Cann, held for no divorce between philosophy and physical science. But it was exactly the philosophy which he desired so much to see that was so conspicuous by its absence from the Rev. Doctor's address. He failed to trace in the address the least acquaintance with those who had attempted to solve the great problem of philosophy—Comte Berkeley or Mill. He had made it his business to make himself acquainted with philosophy, and he believed all men of science did the same, and, if Dr. M'Cann had done so, it would surely not have occurred to him that the theory of the learned and pious Berkeley, Bishop of Clayne, tended to materialism. Surely Dr. M'Cann ought to know that Berkeley had denied the existence of substance apart from its attributes. Dr. M'Cann had contended that consciousness was necessarily to be relied on, but he could not have surely known that the famous maxim of Des Cartes, *Cogito, ergo sum*, had had its foundation broken up in every way long ago, and that no man would care to rest his convictions upon the most unstable of foundations. The learned Professor ridiculed the idea that conscientiousness could be a guide in starting upon so great a problem, and, speaking of Archdeacon Freeman's paper, said he highly commended the courage with which the gentleman had gone back to the Bible for his argument instead of sheltering himself as so many did behind the assertion that the Bible was not intended to teach physical science. He (Professor Huxley) never could understand how men could read the first chapter of Genesis and not see that the writer intended to give an account of the cosmogony. He would, however, say that the Archdeacon's argument was not a new one, and, in fact, a considerable period of his (Professor Huxley's) scientific life had been spent in dealing with those arguments. Archdeacon Freeman had also made a mistake in supposing that the similarity of types was only to be found in the higher animals, for the lower they went, the greater was the similarity.

Drs. Hooker, Wilkes, Vivian, and Professor Wallace also defended the Darwinian theory, and contended that no argument had been put forward in any of the papers which at all affected it. The Rev. J. M'Cann made a spirited reply, in which he quoted as his authority on the reliability of consciousness, Sir John Hamilton, and denied, in general terms, that he had assigned too much power to the faculty in his argument in favour of the introduction of a philosophical method of treating scientific subjects.

SECTION E.—GEOGRAPHY.

THE MOUTH OF THE LIMPOPO.

BY DR. MANN.

THE author gave a description of Erskine's Discovery of the Mouth of the Limpopo. For a considerable time there had been very great difference amongst geographers as to what really was the outlet of the great African river into the ocean. It was a matter of interest upon double ground, because it had been a reproach to geographers hitherto that the outfall of the great river, well known in its higher part, was entirely unknown, and in the next case because there was something to tell of bold and brave adventure on the part of a young man, connected with a geographical result. The gentleman accomplishing it was Mr. St. Vincent Erskine, the young son of the Colonial Secretary of Natal. The reason that made him undertake the journey was that just before he had heard from a great German traveller, who had travelled between the Limpopo and Zambesi, that he had seen old workings of gold mines, and that he had reason to believe there was a rich auriferous district lying around. Dr. Mann read an abstract containing the main points of the account, which was exceedingly interesting. The journey occupied four months. The stream was found to be 300 yards wide at full tide where it flowed into the ocean, and the sea was breaking for three miles out in a succession of small rollers, indicating a shoal coast. There was a broad lagoon shut in by dry sand, except where an open channel, 100 yards long, ploughed through it. He took an observation of the altitude of the sun at noon, showing that the river was 25deg. 15min. South, but he was not able to get the longitude, through having had to abandon his instrument. If he had been supplied with Colonel Strange's instrument it would have been the very thing to have secured him against the unfortunate result. The geological point was that the line of the river taken from its confluence into the Indian Ocean, had been almost accurately laid down, which it had not been hitherto, in the maps. He expressed a hope that the Geographical Society would be true to itself and encourage Mr. Erskine in further prosecuting his work, and get the problem settled so far as the astronomical supply of the accurate longitude of the mouth of the river was concerned.

THE RUNN OF CUTCH, INDIA.

BY THE PRESIDENT.

SIR BARTLE FRERE gave a lengthy and interesting description of the country which lies between India proper and the valley of the Indus, more especially with reference to the curious geographical phenomena marked on the maps as the Runn of Cutch. The nature and peculiar characteristics of this country were so little to be gathered in ordinary maps or books of reference that a few remarks upon it, derived from personal observation, might stimulate those who were in a position to make exact inquiries by means of scientific appliances, to do so. In the maps, between India proper and Rajpootana and the valley of the Indus, appeared a space nearly blank, not because it was unknown or not traversed, but because there was very little to mark on it. It was variously designated as the great Indian Desert, or sometimes as the Thurr, a term which did not convey any very distinct idea to the European mind, and it terminated in a district generally known to our map-makers as appropriated to a marshy tract or morass. He himself did not know any ordinary term used in geography which would precisely describe either of the regions. Cutch was a district 600 miles long, and nowhere less than seventy miles in breadth. It was divided into two great portions. The north was generally marked by great sand hills, and was called the Great Desert, and the southern portion, generally marked as a morass, was called the Runn. The country, however, described as a desert did not answer to our ideas of a desert, because it was inhabited by a people who had the appliances of civilised life, though on a very humble scale and after a very peculiar fashion. They were a very ancient people and much attached to their sand hills. It was not altogether entirely uncultivated either, because there were oases here and there, and in the middle of it was the celebrated city of Jessulmere, the capital of one of the principal Rajpoo dynasties, that had existed there over 1,200 years. The country was hedged in throughout its whole space by sand hills, some of which were said to be 200ft. high. The people generally spoke of the sand hills as having been formed by the wind, but he (Sir Bartle) did not believe that; but, from observations, he came to the conclusion that they were formed by subterranean forces, by an upheaval of the earth during an earthquake. He then described the particular part called the "Runn," which was not a bog, but a perfectly flat hard plain, composed of sand and clay. This district contained no animals, no vegetables, no hollows, nothing that they might expect to see on any part of the earth's surface. It extended for a hundred miles in length and forty miles in width, and formed a very serious obstruction to travellers from the cultivated and peopled portion of Cutch. He would not pretend to solve the problem how this table was formed, but would hazard the conjecture that it was somehow connected with the constant vibration caused by the very active and persistent volcanic action, evidence of which was found in the country around the basin, formed on the one side by the Thurr, and on the south by the semicircular land and Cutch proper. There could be no doubt that volcanic action all round there was more active than in any other part of the world.

Sir Charles Trevelyan thought that the sand hills in the north-western part were more or less connected with the wind. He asked Sir Bartle whether the idea that was prevalent in India that the Runn was an inexhaustible magazine of salt was correct, and whether the salt existed ready made or only to be obtained by evaporation.

The President described the three ways in which salt was formed; and then said that just below the surface of the Runn, extending for miles, sheets of salt had been found 2ft. or 3ft. thick, and there could be no doubt that an action was going on which ages hence might produce such salt caverns as they saw in Cheshire and the Tyrol.

PLAN OF A CANAL TO UNITE THE UPPER NILE WITH THE RED SEA.

BY DR. BEKE.

THIS paper shadowed forth a project for forming a water communication between the Red Sea and the interior of Africa, not by turning the water of the sea inland, as it was said M. Lesseps contemplated doing, and thus submerging the Sahara, or great desert, but by diverging into the Arabian Gulf a portion of the head waters of the Nile. Dr. Beke said of the feasibility of the scheme there could be no doubt, inasmuch as the main features were already formed by nature. The proposed canal would simply follow the line of a natural water-course, running from south-west to north-east, between the sixteenth and nineteenth parallels of north latitude, whilst its operation would be to convey a portion of the waters of the Atbara, the last great tributary of the Nile, into the Red Sea, at a short distance to the south of the port of Suwakin. Sir John Bowring's "Report on Egypt and Candia" (1840) stated, on the authority of M. Linant, that the Ashbarra or Bahr Mogren might easily be turned into the Red Sea at Souakim. It passed over plains and sands, and the remains of a bed or canal already traced by human hands existed from the Ashbarra to the Red Sea; and in 1852 MM. de Malzac and Vayssière proceeded from Surakim up a khor or wady to Fillik, in Taka, and stated that the waters of the Gash, when at their highest, partly found their way to Tokar down the valley, along which they had travelled, while in 1855 Dr. Schweinfürth proceeded from Suwakim to Karsala, and found the Gash to be a tributary, if not identical with the

Wady Langeb. A junction between the Gash at Atbarra might be easily made. Referring to the cotton supply, he pointed to the Egyptian province of Taka and the neighbouring districts watered by the Gash and the Atbarra as a region capable of furnishing to our manufacturers an almost unlimited supply of an article which was absolutely essential to the millions whose subsistence was dependent on the great branch of our national industry. The cotton fields of Upper Ethiopia had occupied his attention for many years past. The regions in question were described by Pliny, the naturalist, as possessing scarcely any trees of importance, except those bearing wool, and that it was from thence that the seeds of the cotton plant were in 1820 introduced into Egypt, where its cultivation made such rapid progress that the quantity exported in 1824 was 30,000,000lb., which, at the Government price, realised £848,478. That was the produce of an exotic plant, of which a stranger, M. Jumel, had accidentally seen a specimen growing in a garden only four years previously. In any case the establishment of this line of transport would be attended with most important and beneficial results, for, in addition to the conveyance of cotton and other products from Taka to the coast, the distance of Khartum on the Nile to the shores of the Red Sea was little more than 400 miles, through a fertile and well watered country, whilst from thence to Egypt it was double the distance by a desolate and difficult route, so that the canal now proposed could not fail to become ere long the main channel for the commerce of Sennaar and the surrounding country, and it would eventually bring into connection with the shores of the Red Sea, and so with the civilised world, the more extensive, most fertile, and most populous regions of inter-tropical Africa. Now that the expedition, under the direction of Sir Samuel Baker, had been set on foot for the exploration, subjugation, and civilisation of those regions, the great importance of this short and direct means of communication with the interior of Africa became still more apparent.

The President thought the paper did not contain such an impracticable suggestion as might at first sight appear.

Dr. Blanc, who, it will be remembered, was one of the captives in Abyssinia, could not quite agree with Dr. Beke's canal. He thought the streams would be too rapid for any boat that had ever been built to live in. Besides that, the natives in that part of the country were Bedouins, who had been roving tribes for centuries, and nothing would induce them to settle down. He was afraid if the canal were made it would not be navigable on account of them, and that it would require the expatriation of those natives from the plains before ships would be able to pass unmolested.

Mr. Trelawny Sanders said he should be sorry if the subject were to stand where Dr. Blanc had left it, for he left the question of the civilization of Africa in a very hopeless state. There were many who looked on that question as one of the grandest that at present agitated the philanthropic world, and this proposition of Dr. Beke's bore upon it. He believed they had only to establish a revival of good government and proper administration over the people of that country, to protect life and industry, to bring about as great a state of civilization as existed there under the Romans. He believed if Western Europe applied its mind to the civilization of Africa that it would be successful. He did not advocate Dr. Beke's details, and merely spoke on the question generally, but he believed the time was not far distant when the mystery that enshrouded the continent of Africa would be removed.

SECTION F.—ECONOMIC SCIENCE AND STATISTICS.

UNIFORMITY OF WEIGHTS AND COINS.

BY PROFESSOR LEONE LEVI.

THIS was the report of the committee on the uniformity of weights and coins, which was presented by the learned Professor in the interest of science. The report opened by stating that considerable progress had been made during the year in the assimilation of weights, measures, and coins in all countries. The North German Confederation had adopted the metric nomenclature, and added corresponding idiomatic names. By a law dated June 13th, 1868, the metre was adopted as the basis of weights and measures, and they resolved to take as a primary measure of length the platinum bar in possession of the Prussian government, which in the year 1863 was found by a commission appointed by the French and Prussian governments to be equal to 1·00000301 metre of the temperature of melting ice by comparison with the metre deposited at the archives in Paris. Still greater progress had been made in the introduction of the metrical system into India, and the report entered into particulars of the same. The committee had made efforts to extend the system to the colonies and dependencies of the empire, and they trusted that before long there would be decided uniformity of weights and measures. The second report of the standard commission, just published, recommended the removal of every difficulty, and the full and legal introduction of the metric system. Chambers of commerce and agriculture (including the Barnstaple Farmers' Club) had petitioned in favour of uniformity. With regard to international coinage no steps had been taken since the report of the Royal commissioners. The Chancellor of the Exchequer, however, had recently enunciated his views in favour of imposing a seigniorage of about one per cent. for converting gold into sovereigns. This was a difficult question, and the committee contented themselves in echoing the recommendation of the Royal commissioners that another international conference be speedily held. The committee, in conclusion, recommended their reappointment with a grant of at least £50, for the purpose of further stimulating the early realisation of one uniform system of weights, measures, and coins in all countries—an object of the highest importance in the interest of science, education, commerce, and peace.

NAVAL FINANCE.

BY MR. ROBERT MAIN.

THIS subject was treated by Mr. Robert Main, of the Admiralty, in an able paper. Its object was to show the causes of increase in naval expenditure in the last twenty years. The increase, which was nearly five millions sterling, involved a positive increase of four millions to taxation. The improvements to the navy, such as the increase to seamen's pay, the increased cost and value of provisions and stores, the extended basin accommodation for ships, &c., accounted for more than a million and a half sterling; nearly the same amount has gone to actual additions to the navy, such as the naval reserve, the maintenance of a large force of seamen in reserve, and the establishment of a Channel squadron; while the remaining million has gone in the establishment of factories, the increased use of steam power in the navy, and the construction of iron-clads. The difficulties, therefore, of financial reformers and economists were greater than in contending against extravagance alone, which was light in comparison to the costliness of the navy now in every point, both in *materiel* and *personnel*. Their exertions would now have to be directed principally to substituting a more elastic system of naval defence for that in existence at the present time.

INTERNATIONAL COINAGE.

BY DR. FARR.

THE author read a very elaborate and learned paper on this subject. He examined at considerable length the proposal of the Chancellor of the Exchequer to charge at the Mint a seigniorage of about one per cent. for coining gold into sovereigns, fully approving of the scheme, and contending that a seigniorage within certain limits need not cause any change in the current value of the sovereign; the sovereign will never purchase less in the market by reason of the Mint charging something (not too much) for converting the metal into the coin, and the only sufferers by the change will be the holders of uncoined gold, and theirs will not be a grievance of any great importance. With regard to international coinage, Dr. Farr recommended, as the international unit of values, a new gold coin weighing ten grains and worth 25s., retaining our present sovereign and half-sovereign for a time, and working them gradually out of circulation. He recommended this in preference to the 25 franc piece for several reasons, especially because the French masters of currency themselves were generally of opinion that the 25 franc piece would not be a convenient standard.

Mr. Burn, of America, contended that while the English sovereign stood at its present value, there would be no international standard. He ridiculed the system of a mixed currency of paper and coin, contending that one or the other should be adopted exclusively. With regard to weights, he pointed out the anomaly of a discrepancy between avoirdupois and troy weight, neither the lb. nor the oz being identical in the two systems.

Mr. F. Fellows argued that if we adopted Mr. Lowe's proposal of a seigniorage upon coining sovereigns, reducing the sovereign from an intrinsic value of 25 francs and twopence to 25 francs, we should lose a very large sum in exchange with France and other countries.

Sir John Lubbock, a member of the Royal Commission on International Coinage, Weights, and Measures, said he was in a minority of one on the commission in favour of charging a seigniorage, and he was glad to find the Chancellor of the Exchequer and Dr. Farr of the same opinion with himself. The sovereign among ourselves would be of the present value, and in exchange with other countries the difficulty suggested by Mr. Fellows would not arise, for we do not pay for imports with coin but with bills, and the value of bills would remain unaltered.

Professor Newton, of the United States, was opposed to Dr. Farr's suggestion of a new common standard worth 25s., as it would overturn every system in the world, and be a change so large as to be an immense inconvenience. What was wanted was a scheme to bring the sovereign and a certain number of francs into identity. In his opinion, the simplest way to do this was to follow up the Chancellor of the Exchequer's scheme of charging a certain seigniorage upon the minting of the sovereign by trying to induce the French Government to charge exactly the same seigniorage for minting the 25 franc piece as our Government would charge for coining the sovereign, and so making the sovereign and the 25 franc piece at once of the same nominal value and the same intrinsic value.

Sir John Bowring was opposed to the Chancellor of the Exchequer's proposal, as one introducing great inconvenience, and spoke strongly in favour of maintaining the English sovereign at its present value, that being the coin best understood and appreciated in every quarter of the world.

AGRICULTURAL ECONOMIES AND WAGES.

BY PROFESSOR LEONE LEVI.

THIS was a most elaborate paper, and one full of interest to the Devon agriculturists. The Professor concluded with the following summary propositions:—

1. That the great causes of low wages in agriculture, as compared with other industries, appear to be the prevalence of physical labour and the permanent and general excess of labourers.

2. That it being highly important for the welfare of the labourer to raise the condition of agricultural labour from that of unskilled to skilled labour, it is necessary to extend elementary education, to promote technical education among farmers and stewards, and to offer liberal remuneration to superior skill and careful working in any of the operations of farm labour by the extension of payment by piecework and the greater adoption of machinery.

3. That, with a view to the greater efficiency of labourers, nothing is more important than that the labourer should receive wages sufficient to maintain him in a condition of health and vigour.

4. That, in order to modify the excess of labourers in agriculture, it is requisite to remove any obstacle, by the law of settlement or otherwise, to the free removal of labourers from county to county, to promote emigration direct from the country districts, to extend the cultivation of land, and to increase the commerce and manufacture of the country.

5. That the difference existing in agricultural wages in different counties in the kingdom, though greatly modified by the allowance in kind in some of them only, mainly arises from a greater or less excess of labour, greater or less efficiency of labour, different degrees of productiveness of the soil, difference in the capital invested in agriculture, and the presence of other industries.

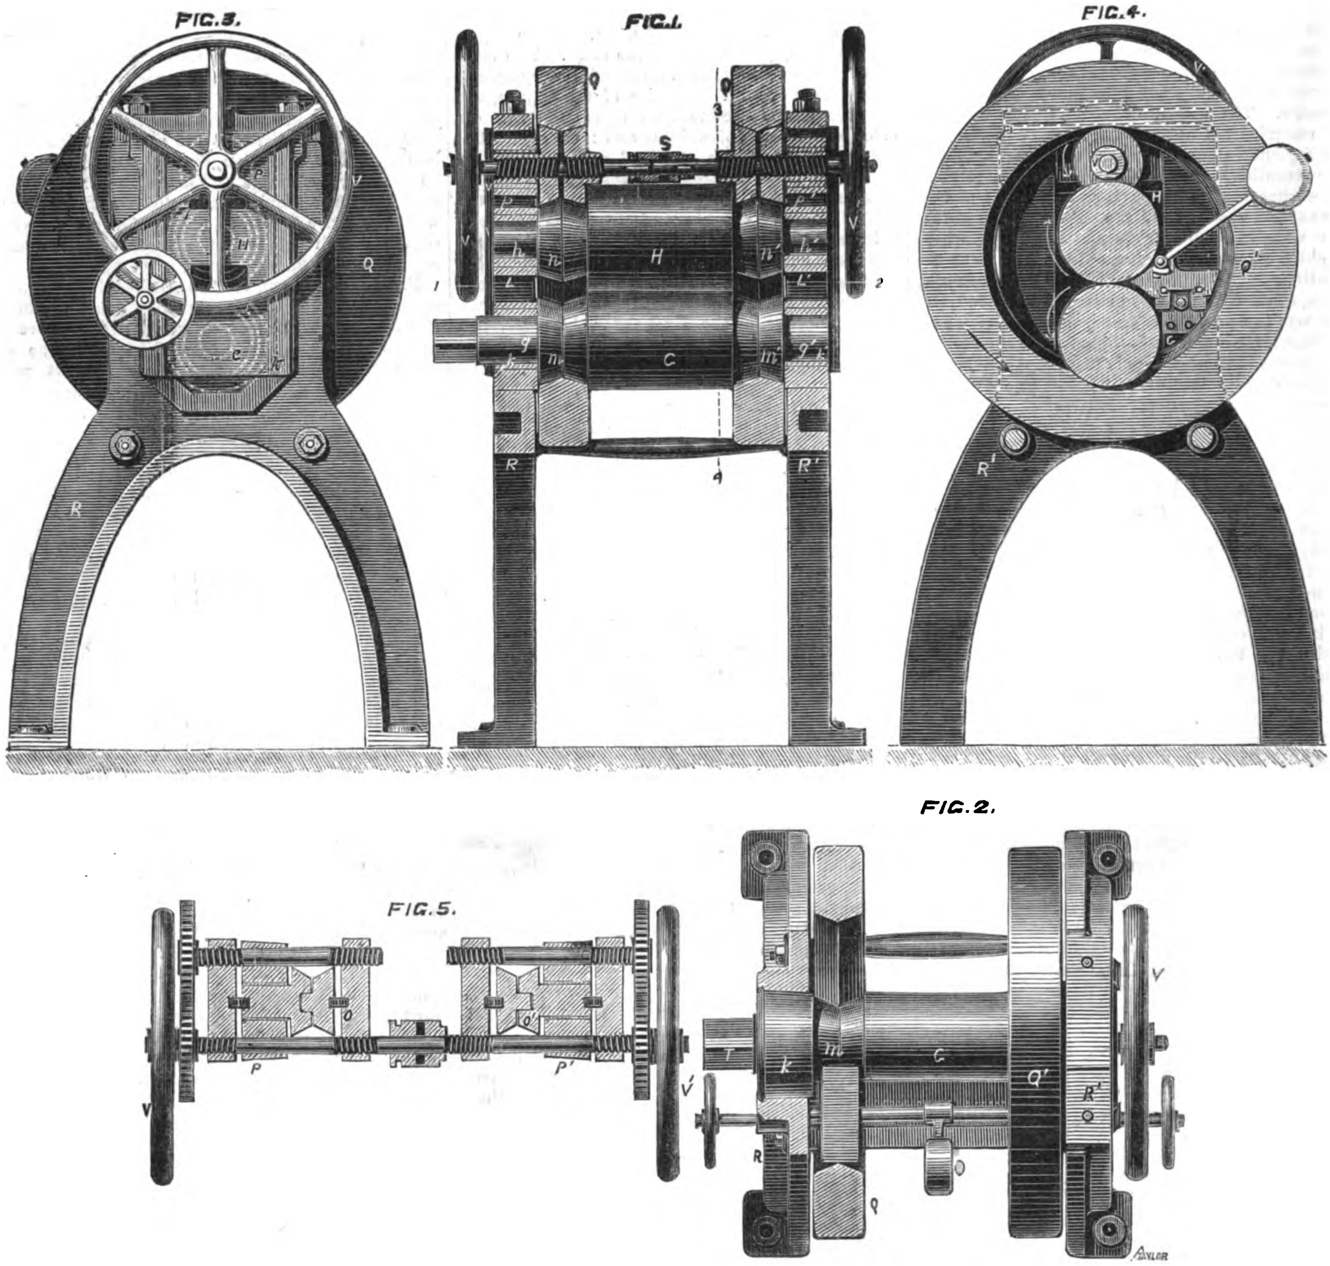
6. That, for the purpose of encouraging the investment of capital in agriculture, it is important to extend the custom of granting long leases, to secure compensations for agricultural improvements, and to remove any inequalities in the burden of taxation wherever they exist, and to extend as far as possible railway accommodation in agricultural districts.

7. That, having regard to the advantages connected with the system of yearly hiring, as the best mode of securing a continuity of labour in the same service, and of promoting the welfare and contentment of the labourers, it is highly desirable to extend the custom in all counties, provided it may be introduced without the objectionable practice of hiring fairs and markets, substituting for them registry offices in all the market towns.

(Continued on page 192.)

ROLLING MILL.

BY M C. MONGIN.



IMPROVEMENTS IN ROLLING MILLS.

THE invention illustrated in the accompanying engraving has for its object to convert the sliding friction of the axles of the rolls of rolling mills in their bearings into a rolling friction, and thus to obviate almost entirely the loss of power which results under existing arrangements from the first-named friction. For this purpose the rolls have gudgeons running in ordinary bearings in the headstocks as hitherto, but these bearings do not take any of the upward and downward pressure exerted by the rolls, but only serve to steady them in their motion, the pressure being taken by the following arrangement:—At the inner side of the headstocks or framing, necks are formed on the rolls, the necks on the lower roller being made with V groves, while those of the upper roller are made with projecting V surfaces. The necks of the lower roller take a bearing directly upon corresponding projecting V surfaces on the inner circumferences of large strong rings or hoops which pass round the necks of both rollers, being of such a diameter, however, that the upper roller does not bear directly upon their inner surface, but through the intervention of antifriction rollers having V grooves corresponding with the V surfaces of the upper roller and the ring.

From this arrangement it will be seen that when reversed motion is imparted to the rolls in the ordinary manner, on the metal to be acted upon being passed between them the pressure of the lower roller will be taken at the lowest point of the ring, while that of the upper roller will be transmitted by the antifriction roller to a diametrically opposite point of the rings. As the antifriction rollers transfer the rotary motion of the upper roller to the rings in the same direction as the motion imparted to them by the lower roller, it follows that the rings will be caused to travel round as the rolls revolve, and the necks of the lower roller will consequently roll on their inner surfaces, while the necks of the upper roller will roll on the antifriction rollers. In place of imparting the required motion directly to the rolls it may be imparted either by toothed gearing or by driving belts to the revolving rings, or even to the antifriction rollers. The adjustment of the rolls nearer to or farther apart from each other may be effected by making the antifriction rollers of two parts, divided in a direction at right angles to their axis, and connecting them by right and left handed screws, by turning which the two parts may be either brought nearer together, thereby forcing the upper roller nearer to the lower roller, or be moved farther apart, thereby allowing greater play between the rollers. We would here observe that this invention is due to M. Charles Mongin, of the well-known firm of Ch. Mongin and Co., saw manufacturers, of Paris, and has recently been patented in England.

Figs. 1 to 5 in our engraving show the improved construction of rolling mill. Fig. 1 shows a longitudinal section of the same; fig. 2 shows a part plan and part sectional plan on line 1 2, fig. 1; fig. 3 shows an end elevation; fig. 4 shows a transverse section on line 3 4, fig. 1. The lower roll G rests with its trunnions g and g^1 in the brasses $k\ k^1$, fixed in the guides of the side frames R R^1 while the upper roll H rests upon the lower roll The trunnions $h\ h^1$ of the upper roll carry brasses L L^1 situated between the guides of the side frames, and the upper roll carries the rollers O O^1 resting upon the parts $n\ n^1$ of the roll, which rollers carry on their trunnions the brasses P P^1, also working between the guides of the side frames. Lastly, two strong rings Q Q^1 rest upon the rollers O O^1.

As shown in fig. 1, the inner surfaces of the rings Q Q^1 are V shaped, and fit accurately into the peripheries of the rollers O O^1 formed with V grooves, into which fit also the V surfaces of the parts $n\ n^1$ of the roll H, while the peripheries of the parts $m\ m^1$ of the roll G are formed with V grooves fitting accurately upon the V surface of the rings Q Q^1; these latter are consequently prevented from altering their position laterally upon the rolls. The rollers O O^1 are made in halves connected together by the right and left handed screw spindles $v\ v^1$, by turning which by means of the handwheels V V^1 the two parts of the rollers may be brought closer together or moved farther apart, thus allowing greater or less play between the parts $m\ m^1$ of the roll G and the inner circumference of the rings Q Q^1. If now the metal to be rolled be introduced between the rolls these will be forced asunder until the inner surfaces of the rings Q Q^1 are pressed against the parts $m\ m^1$ of the lower roll, whereupon, if rotary motion be imparted to

MACHINERY FOR FORGING.

BY MR. W. CLAY.

FIG. 1.

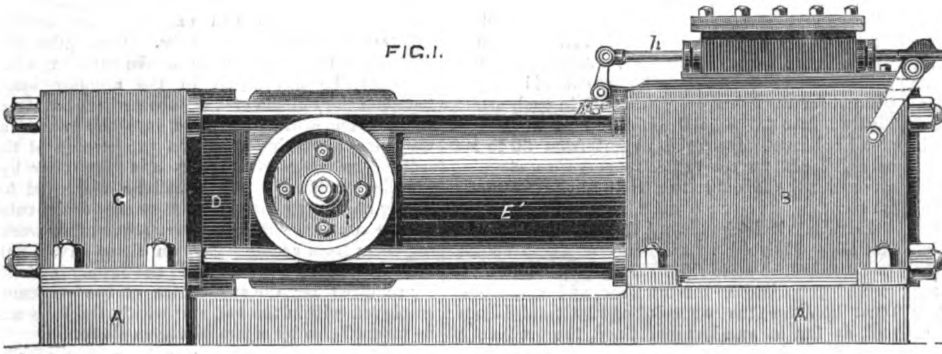


FIG. 4.

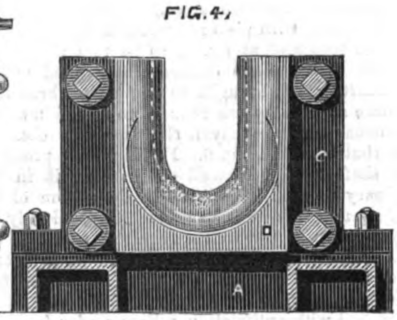

FIG. 6.

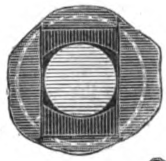

FIG. 2.

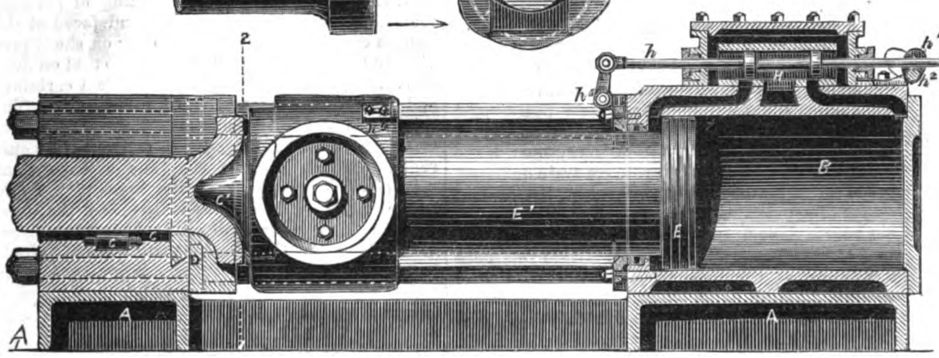

FIG. 3.

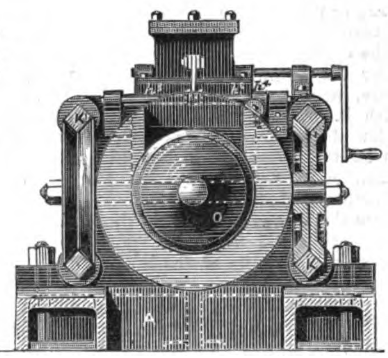


the latter in the direction of the arrow, fig. 4, it will impart motion in the same direction to the rings Q Q^1, and these will in their turn impart motion in the same direction to the rollers O O^1, which will consequently impart to the upper roll H the requisite rotary motion in the reverse direction to that of the roll G.

The space between the rolls is regulated for rolling different thicknesses of metal by screwing the two parts of the rollers farther apart or nearer together, as already described. In the arrangement of screw spindles shown for this purpose it will be seen that the screw spindles and their wheels V V^1 revolve with the rollers, and consequently it might be difficult to regulate these while in motion. In place, therefore, of this arrangement, that shown in sectional plan at fig. 5 may be used, in which the two halves of the rollers bear against two crossheads, through which work two right and left handed screw spindles carried by the framing P P^1, whereby the wheels V V^1, and consequently the rollers, can readily be operated, and thus the thickness of the metal be reduced while the rolling mill is in motion. In either arrangement of mechanism for regulating the distance of the rolls an oblique position may be imparted to the latter so as to roll the metal of a greater thickness on the one side than on the other, by screwing the two parts of one roller nearer together than the parts of the other roller, which may be readily effected by rendering the screw spindles independent of each other by disengaging the clutch S.

From this arrangement it will be seen that the pressure exerted by the rolls, instead of being transmitted to their bearings in the headstocks, as is usually the case, is transmitted through the rollers O O^1 to the revolving rings Q Q^1, whereby the great loss of power arising ordinarily through the sliding friction in the bearings is almost entirely obviated by substituting rolling friction for such sliding friction. This system may be readily applied by means of slight modifications to all existing rolling mills; and where it is not desired to render the gauge of the rolls adjustable, the arrangement may be simplified by making the rollers O O^1 of one piece and without the adjusting mechanism. In this case the rollers might with advantage be replaced by a third roll formed similarly to the roll H, so as to constitute a three-roll mill. The motion may be imparted to the mill either through a coupling on the trunnion of the one roll, as indicated at T, or by driving the rings Q Q^1, either by driving belts or by forming teeth on their periphery in gear with spur driving gear.

MACHINERY FOR THE MANUFACTURE OF FORGINGS.

MR. WILLIAM CLAY, of Liverpool, has patented an invention which relates to that class of forgings known in the trade as heavy forgings, the object sought being to ensure sound forgings, which it is very difficult to obtain when manufacturing bulky articles, the thickness of the metal in which greatly and suddenly varies. In manufacturing, for example, marine engine shafts with disc couplings the point of junction of the disc with the shaft will generally be found when cut into to exhibit internal fissures which greatly detract from the strength of the shaft. In order to avoid this defect and to ensure solidity throughout the metal of large forgings, Mr. Clay proposes when forming heads, collars, or flanges upon the ends of shafts or rods to employ a horizontal hammer of peculiar construction, which is connected with and operated by a piston working in a horizontal steam cylinder, and thereby materially to reduce the sectional thickness of the metal at the line of junction of the head, collar, or flange with the shaft.

In the accompanying engraving, fig. 1 shows in side elevation the kind of steam hammer which Mr. Clay employs in manufacturing heavy forgings; fig. 2 is a partial longitudinal section of the same; fig. 3 is a transverse section taken at the line 1 2 of fig. 2, and looking in the direction of the arrow; and fig. 4 is a transverse section taken in the same line, but looking in an opposite direction. A A is the bed of the machine formed in one casting. To one end of this bed the steam cylinder B is bolted, and to the other is secured a block C for receiving on its face the anvil D. The face of this anvil is shaped to correspond to the form the end of the shaft is intended to receive by its lateral expansion, and in order to allow of the anvil being changed to suit different sizes or kinds of work it is made to fit into V's formed on the face of the block C. The anvil is U-shaped, as shown at fig. 4, and the block has a corresponding vertical hollow to enable it to receive the heated shaft that is intended to be brought under the action of the hammer. To facilitate the turning of the shaft on the anvil the block C is fitted with antifriction rollers *c c c* which support the shaft when it is presented to the hammer. E is the piston of the cylinder B, fitted to a cylindrical trunk E^1, which carries at its other end the hammer block.

Fitted centrally in the face of this block is a conical piece G^1, which forms the striking part of the hammer; its object is to form a cavity in the end of the shaft, and thus by reducing the thickness of the metal at that part to remove the liability of fissures occurring in the forging. H is the slide valve, the rod *h* of which extends through the opposite ends of the valve box. At its rear end this rod is formed into a link to receive a cam h^1, which is keyed to a cross shaft h^2. This shaft rocks in bearings on the top of the cylinder B, and it is fitted with a handle, by raising or depressing which the attendant is enabled to operate the valve, and thus regulate the advancing and retrograde movements of the hammer at pleasure.

To prevent the risk of damage to the machinery from inattention the valve rod is jointed at its front end to the arm of a rock shaft h^3 mounted in bracket bearings at the front of the cylinder B, and fitted with a pendant arm h^4 carrying an antifriction bowl. In a line with this bowl on the hammer head is fitted an adjustable stop h^5, which as the piston is nearing its back stroke will strike the bowl of the arm h^4 and rock the shaft h^3. This motion of the rock shaft will, by reason of its connection with the valve rod, cause the valve to advance and cut off the supply of steam to the cylinder, while at the same time it will stop the escape of the exhaust steam, and thus provide an elastic cushion for the piston to strike against.

An incidental advantage derivable from making the cylindrical trunk E^1 of the large diameter indicated in the engraving is that it will allow of but a small amount of steam being used in the return stroke of the piston, while a powerful propelling force may be used for its advance. The hammer head is fitted with a pair of V-grooved wheels I, which turn freely on a fixed axle that passes through the hammer head. These wheels are intended to carry the weight and facilitate the traverse of the hammer, and for this purpose they run upon and between angular rails K K^1, which constitute also tie rods for connecting the cylinder B and blocks C together, and enabling the machine the better to resist the strain to which it is sub-

jected. The lower rails K serve as track rails for the traverse to and fro of the hammer, and the upper rails K ' assist in steadying the wheels on the track rails.

In order to form a head or enlargement on a shaft according to Mr. Clay's invention he first takes a shaft forged in any approved manner, and piles the end with pieces of wrought iron, after the manner indicated at fig. 5, so as to approximate roughly to the shape desired. The piled end of the shaft is next brought to a welding heat in a furnace and the pieces reduced to a solid mass in the usual way, whereby a shaft head is obtained like that shown at fig. 6. Having thus prepared the shaft forging instead of finishing it in the ordinary way it is submitted to the action of the forging machine we have described, previously reheating the shaft, if that is required, to enable the machine to act efficiently upon it. The heated shaft is placed with its head opposite the hammer head, as shown at fig. 2, in the block or rest C, furnished with antifriction rollers c c for facilitating the turning of the shaft when required. The head of the shaft overlies the anvil which forms the face of the block C, and the hammer by reason of its shape will, in delivering its blows, form a conical hollow in the head of the shaft, and thereby to a considerable extent reduce the bulk and equalise the thickness of the metal at the centre or the junction of the head with the shaft. By turning the shaft from time to time on its axis as the operation proceeds its head will be reduced under the blows of the hammer to a regular figure, requiring comparatively little turning to finish it. This mode of forging thick portions hollow also ensures a more equable contraction of the metal when cooling than hitherto, and the formation of fissures in large forgings of the character illustrated will be thereby avoided. To ensure the best practical effect the cooling of the metal (when the forging is completed) is commenced at the centre of the head by the application of a jet of water or other cooling medium. By thus causing the metal to shrink towards the interior instead of the exterior the chief difficulty of obtaining sound forgings will be removed.

(Continued from page 189.)

8. That whilst payment in kind is objectionable, as it is liable to great abuse, produces much uncertainty, throwing the dangers of the market on the party less able to bear them, it is still more objectionable where any part of the wages is paid in the shape of cider or spirits.

9. That the bondage system prevailing in Northumberland operates most unjustly to the labourer, and acts most disadvantageously on the moral condition of women in that district.

10. That, upon a comparison of the purely agricultural with the purely industrial counties, the agricultural exhibit a smaller rate of births, deaths, and marriages, a better state of education among the adults, especially among women, nearly an equal proportional number of children at school, less drunkenness, and less crime, but more pauperism and more illegitimacy than the industrial counties.

11. That the house accommodation in the rural districts appears to demand decided improvement, many of the old cottages being inconsistent with the moral and physical well-being of their inhabitants.

12. That it were much to be desired that to every cottage a small garden should be attached; and that where that is impossible an allotment of land, conveniently situated, should be granted with it.

13. That for the purpose of stimulating habits of self-reliance and independence of character among the agricultural labourers, it is most important to restrict as much as possible the operation of the poor law, to promote the establishment of savings banks, insurance companies, and friendly societies under proper control, and to limit to the utmost extent the licensing of public-houses and the inordinate consumption of spirits.

14. That, taking into account the large excess of agricultural labourers, and the probability of a still further displacement of labour in proportion with the introduction of machinery and skill, the need of regulating the efflux of such labourers to the towns and manufacturing districts in relation to the power of commerce and manufactures to absorb them; the importance of procuring the contentment of such agricultural population, and the universal desire of the most industrious among them to own a plot of land or to farm it on his own account; as well as the great advantage of offering means for the investment of savings in the mode most consonant with their habits, and in almost the only way within their reach, it seems highly expedient, even regardless of other economic considerations of a conflicting character, that facilities should be afforded for the purchase of lots of land of reasonable size, capable of being cultivated by the proprietors themselves; that any land now held by corporate or public bodies should be appropriated for that purpose; and that in each estate, divided into large holdings, a limited number of small holdings, varying in extent from 30 to 100 acres, should be set aside, to serve as stepping stones for the labourer to rise to the position of a farmer.

15. That it is important that the agricultural statistics published by the Board of Trade should be extended, so as to show the number and extent of land proprietors, the number and acreage of farm holdings, the wages of agricultural labour, and, as far as can be ascertained, the produce of the soil.

SECTION G.—MECHANICAL SCIENCE.

THE CHANNEL RAILWAY.

BY MR. J. F. BATEMAN.

THE author referred at some length to the advantages which would accrue from a continuous railway communication between England and France, and to the various proposals for effecting that object by a tunnel to be driven beneath the bed of the sea—by submerged roadways and tubes—by large ferry boats carrying trains on board—and by bridges to be carried on piers formed on islands to be sunk in the Straits. A ferry boat, large enough to receive a whole ordinary train on board, would be a material improvement on the present means of conveyance. Such boats, however, cannot be employed, except by the construction of special harbours on each coast. With reference to a tunnel, it has been proposed to drive one of ordinary size for a double line of railway, which shall descend by a gradient of 1 in 60 on each side of the Channel to a depth of about 270ft. below the bed of the sea. The total length of the tunnel would be thirty miles, of which twenty-two would be beneath the sea. A special commission, appointed by the Emperor of the French recently reported in favour of a submarine tunnel. We propose to lay a tube of cast iron on the bottom of the sea, between coast and coast, to be commenced on one side of the Channel, and to be built up within the inside of a horizontal cylinder or bell, or chamber, which shall be constantly pushed forward as the building up of the tube proceeds. The bell or chamber within which the tube is to be constructed will be about 80ft. in length, 18ft. internal diameter, and composed of cast-iron rings 8in. thick, securely bolted together. The interior of the bell will be bored out to a true cylindrical surface like the inside of a steam cylinder. The tube to be constructed within it will consist of cast-iron plates, in segments 4in. in thickness, connected by flanges bolted together inside the tube, leaving a clear diameter of 13ft, Surrounding this tube and forming part of it, will be constructed annular discs or diaphragms, the outside circumference of which will accurately fit the interior of the bell. These diaphragms will be furnished with arrangements for making perfectly water-tight joints for the purpose of excluding sea water and securing a dry chamber, within which the various operations for building up the tube, and for pressing forward the bell as each ring of the tube is added, will be performed. There will always be three, and generally four, of these water-tight joints contained within the bell. A clear space between the end of the tube and the end or projecting part of the bell of 36ft. will be left as a chamber for the various operations.

Within this chamber powerful hydraulic presses, using the built and completed portion of the tube as a fulcrum, will, as each ring is completed, push forward the bell to a sufficient distance to admit the addition of another ring to the tube. The bell will slide over the watertight joints described, one of which will be left behind as the bell is projected forward, leaving three always in operation against the sea. The weight of the bell and of the machinery within it will be a little in excess of the weight of water displaced, and therefore the only resistance to be overcome by the hydraulic presses when pushing forward the bell is the friction due to the slight difference in weight and the head or column of water pressing upon the sectional area of the bell against its forward motion. In like manner the specific gravity of the tube will be a little in excess of the weight of water which it displaces; and in order to obtain a firm footing upon the bottom of the sea, the tube will be weighted by a lining of brick in cement, and for further protection will be tied to the ground by screw piles, which will pass through stuffing boxes in the bottom of the tube. These piles will, during the construction of the tube within the bell chamber, be introduced in the annular space between the outside of the tube and the inside of the bell, and will be screwed into the ground as they are left behind by the progression of the bell. The hydraulic presses and the other hydraulic machinery, which will be employed for lifting and fixing the various segments of the tube, will be supplied with the power required for working them from accumulators on shore on Sir William Armstrong's system, and the supply of fresh air required for the sustenance of the workmen employed within the bell and within the tube will be insured also by steam power on shore.

As the tube is completed, the rails will be laid within it for the trains of waggons to be employed in bringing up segments of the rings as they may be required for the construction of the tube, and for taking back the waste water from the hydraulic presses, or any water from leakage during the construction. The tube will be formed of rings of 10ft. in length, each ring consisting of six segments, all precisely alike, turned and faced at the flanges or joints, and fitted together on shore previously to being taken into the bell, so that on their arrival the segments may, with perfect certainty and precision, be attached to each other. The tube when laid will be secure from all dangers arising from anchors or wrecks or submarine currents. The building of the tube will be commenced on dry land above the level of the sea, and will be gradually submerged as the tube lengthens. The first half mile will test the feasibility of construction, for that will have to be built both above and under water. When once fairly under water the progress should be rapid, and it is estimated that the whole undertaking may be easily completed in five years.

The precise line to be taken will probably be between a point in close proximity to Dover and a point in close proximity to Cape Grisnez on the French coast, where the sea bed on this line appears to be the most uniform in level, and, while free from hard rocks and broken ground, to consist of coarse sand, gravel, and clay. The average depth of water is about 110ft., the maximum about 200ft. On the line suggested the water increases in depth on both sides more rapidly than elsewhere, although in no instance will the gradient be more than about 1 in 100. The tube, when completed, will occupy about 16ft. in depth above the present bottom of the sea. Up to the point on each shore at which the depth of water above the depth of the tube would reach (say) 30ft. at low water, an open pier or other protection would have to be constructed for the purpose of pointing out its position, and of preventing vessels striking against the tube. The tube at each end would gradually emerge from the water, and on arriving above the level of the sea would be connected with the existing railway systems. The distance across the Channel on the line chosen is about twenty-two miles.

The tube as proposed is large enough for the passage of carriages of the present ordinary construction, and to avoid the objections to the use of locomotives in a tube of so great a length, it is proposed to work the traffic by pneumatic pressure. The air will be exhausted on one side of the train and forced in on the other, and so the required difference of pressure will be given for carrying the train through at any determined speed. Powerful steam engines, for exhausting and forcing the air into the tube, will be erected on shore at each end. This system of working the traffic will secure a constant supply of the purest air. By this system of working there would scarcely exist the chance of accident—no collision could take place. There would never be foul air within the tube. The pneumatic system can be as cheaply worked, and be in every way preferable to locomotive power. Combined goods and passenger trains might be sent through the tube at twenty miles an hour, with occasional express trains at thirty miles an hour. The estimated cost of the whole undertaking is £8,000,000. Mr. Chalmers estimated the total annual revenue at £1,800,000. The working expenses would be amply covered by £150,000, leaving about 14 or 15 per cent. dividend.

Mr. Bidder remarked that this subject had not been without interest to him, as it would be recol-

lected that he made a few remarks on it when presiding over the Section at Norwich last year. The atmospheric system, which was a very old subject, and which had been tried to a very great extent in this neighbourhood, failed on account of using a small tube with a large pressure, but it was different with a large tube. He believed the pneumatic principle was the only one that could be adopted to work the tunnel. He thought there would be a difficulty in getting the united actions of the two Governments to carry out the work. Unless the tunnel was worked pneumatically, he would rather cross in the present boats. Until an experiment had been made to test this plan, and the probable cost, it would be more reasonable to construct a huge breakwater and build vessels that should be adapted to cross, except on special occasions, with certainty and despatch.

Mr. C. Vignoles believed that if ever there was to be a tunnel to Calais it must be on this principle. The real cause of the failure of the atmospheric system was not as Mr. Bidder put it, but from an accumulation of heat in the air pumps. It would never pay as a commercial undertaking, as there was not sufficient traffic; but it might be done by the Governments. They, as engineers, considered the scheme a practical one; but he was afraid it must be left to the next generation to carry out.

Mr. Bateman, in reply, contended that the cost would not exceed his estimate.

TRAIN COMMUNICATION.

BY MR. F. VARLEY.

THIS was a paper on a system of communication between guards and passengers on railway trains when in motion. The system was applied in 1866, and is now in use on the Royal train, and it has since been adopted in other trains. The author believed electricity to be the best agent for signalling on rolling stock, and the difficulty in applying it, he believed, was more with reference to the mechanical parts than the electrical. Three electrical systems had been applied to railway travelling, one used by Mr. Preece, on the South-Western Railway; one by Mr. C. V. Walker, on the Great Eastern Railway, applied to trains which run twenty miles without stopping; and one by Mr. Martin, on the North-Western Railway, and this was the one which formed the subject of this paper. Insulated wire is run underneath the carriages, and the ironworks, the coupling bars, and the wheels are connected electrically together. Two insulated wires (one of which is connected with the wire underneath the carriages, the other to the ironwork) are led up to each compartment, and when these two wires are brought in contact the telegraph circuit is closed, and the alarum set ringing. The carriages are connected together by means of flexible conductors, and these are also laterally connected with the insulated wire underneath the vehicles. The apparatus in the guard's van consists of a battery placed in a box and an electric alarum, and on the engine is another alarum. By moving a handle in any of the carriages the alarums are set going. The action of moving the handle sets free a spring, and the handle is locked and cannot be put in its original position until the spring or lock is opened, which is done by means of a key in the possession of the guard. No electrical knowledge is needed to work or keep in order the apparatus, the maintenance of it is not costly, and the alarums, batteries, &c., can be easily shifted from one train to another. At the request of the Board of Trade, in 1866, a train was fitted up with this apparatus which had travelled 250 miles each day, and been started and stopped by its means.

GOVERNMENT INSPECTION OF BOILERS.

BY MR. L. E. FLETCHER.

MR. FLETCHER read the report of the committee on boiler explosions. The conclusions at which the committee arrived were—First, that a lamentable loss of life is annually caused by steam boiler explosions, which urgently calls for public attention. Second, that these explosions, as a rule, are not accidental, but may be prevented by the exercise of common knowledge and common care. Third, that the present investigations conducted by coroners with regard to steam boiler explosions are eminently unsatisfactory, and call for immediate improvement. Fourth, that coroners should, when conducting inquiries on boiler explosions, be instructed and empowered to avail themselves of competent engineering advice, so that the cause of every boiler explosion may be fully investigated, while the information acquired should be widely circulated. Fifth, the committee entertain a sanguine hope that this course alone would do much towards the prevention of the present recurrence of steam boiler explosions, without any further Governmental action.

Mr. Fletcher subsequently read a paper on Government action with regard to boiler explosions. It was, he said, a question whether it is expedient or not for the Government to interfere in the matter of the prevention of steam boiler explosions; and if so, in the second place, what would be the best mode for action to be taken. It is proposed that the Government should take the supervision of every boiler in the country, with the exception of locomotive and marine, and through the medium of the Board of Trade should test all new boilers, and periodically examine them when set to work, as well as all others already in use. Another plan is to render inspection compulsory, but not that Government should take the task of examining boilers into its own hands. A third plan was that the user should be free to use his boiler as he pleased, but would be responsible for any accident, and liable to an action for injury or loss of life in case of an explosion. This last plan, it was urged, would, if adopted, arouse to suitable vigilance those connected with the use of steam, which was all that was required.

Mr. Alcock was of opinion that inspection on the part of the Government was not desirable. The result of Government supervision might be seen in mines, where explosions frequently occur. He thought the present law would sufficiently punish any neglect. A comparison of the number of boiler explosions in 1860 and 1868 would show that the insurance companies were doing good work.

Mr. Bramwell believed that the whole of the deaths resulting from the boiler explosions of last year was not one-fourth of the number of persons who were run over and killed in the streets of London. The coroner's court should be made more efficient. He threw out two suggestions—(1) that there should be a Government inspector to whom persons using boilers might apply for inspection; and (2) that no person should be allowed to make a boiler who was not efficient.

Captain Galton thought the best way to secure safety was to apply to the insurance company, and said he had got the whole of the steam boilers under the authority of the War Office placed under the Boiler Explosion Prevention Company. He thought the persons using steam should be responsible for explosions.

A gentleman pointed out that the inspectors under the Factory Act had power to inspect dangerous machinery, and suggested that they should have authority to call in the aid of a suitable person to inspect the boilers.

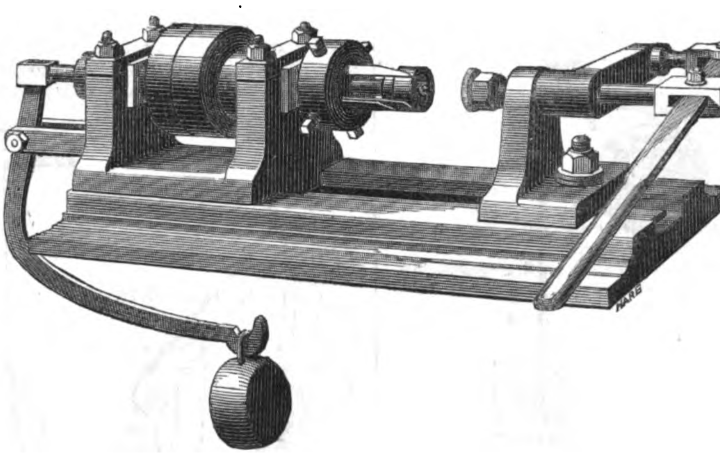
Professor Rankine said he never knew a boiler explode, except from weakness. He preferred to throw the responsibility on the boiler user.

Mr. Fletcher said that for three persons killed by railway accidents, one was killed by boiler explosion. He thought the system of insurance of boilers was wrong, as it led people to try and get their boilers insured rather than inspected.

The President agreed with what seemed to be the general opinion of the Section, that Government interference was undesirable. He also thought that some improvement should be made in the coroner's investigation. A vote of thanks was given Mr. Fletcher for his paper.

SHIVE-CUTTING MACHINE.

BY MESSRS. REDUP AND BRIGGS.



REDUP AND BRIGGS' SHIVE-CUTTING MACHINE.

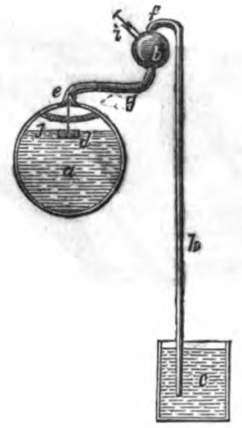
AT the late Manchester Show we came across a very neat and convenient little machine for cutting shives or wooden bungs from solid wood. It was designed and patented by Messrs. Redup and Briggs, and is manufactured by Messrs. Hayward Tyler and Co., of Upper Whitecross-street. Referring to the accompanying engraving, which we find in the "Brewers' Journal," it will be seen that the machine consists of a cast-iron bed-plate similar to that of a lathe-bed, with a fixed headstock having a hollow mandrel revolving freely in gun-metal bearings. Inside this mandrel is a steel rod, which passes through the mandrel for its entire length, and projects at each end. At one end of the hollow mandrel is the gun-metal chuck, in which are fixed, by means of set screws, the four steel cutters by which the cutting of the shive is performed. These cutters are flexible to a certain extent, so that they can be expanded by the brass disc which is carried by the end of the steel spindle, but which is free to revolve with the cutters. The hollow mandrel is fitted with the fast and loose belt pulleys. It will be observed that the outer end of the steel rod is pressed upon by one arm of the bent lever, the other arm being loaded with an iron weight, which tends to force the brass disc already mentioned towards the movable headstock, leaving the cutters free to close to the diameter of the disc, which determines the size of the small end of the shive. The movable headstock on the right can be screwed down at any required distance, and is fitted with a lever handle and sliding bar, having screwed on its end a brass socket, on which is fixed a wood disc, the use of which will presently be seen. The sliding bar is moved longitudinally by the lever handle.

So far the description of the machine; next as to the manner in which it is worked. The piece of wood from which the shive is to be cut is held against the wooden disc fixed on the brass socket by the left hand, and by means of the lever it is then pressed against the revolving cutters. As it is forced towards the fixed head, it comes in contact with the end of the rod, which is pointed, and this rod, being acted upon by the weighted lever, holds the wood steadily against the disc. The cutters, when they first enter the wood, cut out a narrow circular groove, the inner diameter of which is equal to that of the smaller end of the shive. But as the wood is forced towards the fixed headstock the cutters are gradually expanded by the brass disc and they are thus made to give the shive its proper tapered form. After the wood has been cut through, the lever is drawn back, and the finished shive is then forced from between the cutters by the weighted lever operating on the sliding rod within the hollow mandrel. We should mention that one of the cutters has a slight projection on its inner side, which cuts the chamfer on the small end of the shive. By placing packing pieces beneath the tools and changing the disc, shives of any required diameter can be cut, packing pieces and discs of various sizes being supplied with the machine. The shives can be cut from oak staves or any waste pieces of wood, and the machine is easily operated by a boy. We may add that these machines are already in use at Messrs. Bass's, Ratcliffe, and Gretton's establishment at Burton-on-Trent, as well as in other breweries, favourable reports being received of their working.

THE number of visitors to the Patent Office Museum, South Kensington, for the week ending September 4 was 5,100. Total number since the opening of the Museum, free daily (May 12, 1858), 1,636,497.

A NEW INJECTOR.

THE apparatus here figured, from "Cosmos," is the invention of M. Delaurier, who names it the "Automatic Alimenter." It is adapted for use at



all pressures, and acts, as will be seen, without the aid of any machinery. The manner in which it functions is as follows:—In the boiler *a* is a float *d* which descends as the level of the water falls and opens a valve *e* communicating with a closed vessel *b* containing water. Steam taking the place of this water forces it down into the boiler, and then the float *d* rises and closes the valve *e*. Almost as soon as the valve is shut, the steam condenses, and a vacuum is made in the closed space *b*; then another valve *f* at the top of the vessel opens, and water ascends from the reservoir *c* to be let out again at *e* as before. In this way, the water in the boiler is always kept at the same level.

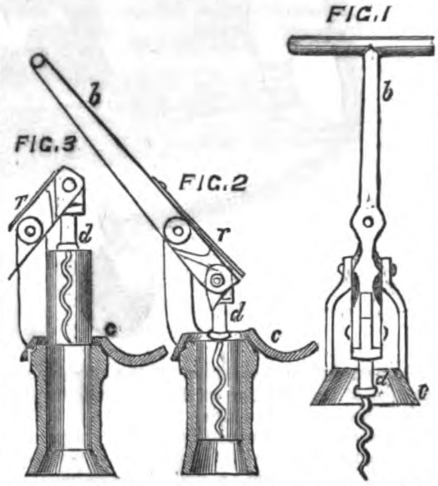
To set the apparatus in action for the first time, it is, of course, necessary to remove air from the space *b*, which is done by means of a small air pump *i*. This is worked until the space is filled with water, after which the apparatus functions of itself, but it is well to give the pump a few strokes occasionally, to be certain that the space is kept clear of air.

To make sure that the valve *e* is either completely opened or closed, there must be some slight friction to retard the movement a little. This is given by the piece of metal *j*, through which the rod of the float slides. The delay gives time for all the water in the space *b* to run out; and then, there being an excess of water in the boiler, the float is kept for some time pressed against the valve *e*. Without this slight modification the apparatus would not act at all or only very imperfectly. The reservoir of cold water *c* may be ten yards below the level of the valve *f*.

A NEW CORKSCREW.

IN spite of the numerous ingenious mechanical devices which have appeared from time to time with the object of substituting the principle of the lever for the muscular exertion of the individual, the latter still remains the favourite and the surest method of drawing a cork. It is also the quickest; for dividing the operation into two parts, that of screwing in the screw and that of extracting the cork, the manner of effecting the former is common to all the methods ever proposed or invented. If we suppose a couple of bottles, into the cork of one of which the screw of an ordinary corkscrew is inserted, and into the other that of any of the patented inventions, and one of the bottles delivered to an expert "waiter," and the other to one equally well practised in the manipulation of the patent screw, there is no question but that the cork will be whipped out by the ordinary screw in less time than it will be extracted by the other. It is quite true that to draw a tight cork with a common corkscrew requires an amount of physical exertion which is beyond the powers of a woman or girl unless she is well practised in the operation and has acquired the "knack," for although occasionally a good pull is indispensable, yet in the main it is the wrist which really does the job. Connoisseurs and old parties who vaunt the merits of the "wine with the green seal" complain, and justly too, of the "shaking" which the bottle suffers by the use of the ordinary screw, but it must be borne in mind that while most of the patents obviate this acknowledged defect, yet it is only when they are properly handled. An inexperienced hand will "shake" a bottle infinitely more by an abortive attempt to use a lever screw than if he understands how to draw a cork adroitly by the common screw.

A new description of screw has lately been patented by Messrs. Jafroy Brothers, of Paris, which is less complicated, has fewer parts, is more effective and cheaper than those already before the public. It is represented in the accompanying cuts, and a brief description will render it per-



fectly intelligible. Owing to the disposition of the levers the cork can be extracted very gently and with great facility. There are five parts in this screw, but they are not detached, as is frequently the case, and consequently there is no chance of the screw being rendered useless by the loss or mislaying of any one piece. Referring to the cuts, *b* is the handle, which may be of wood, horn, ivory, or any other suitable material. The screw is screwed into the socket *d*, which allows of its being replaced when broken or worn out without necessitating the loss of the rest of the apparatus. The spring *v* is mounted in a manner which permits of its ready replacement by any locksmith, and the cap *c* is lined with an internal leather collar. The screw itself presents no feature of particularity, being identical with those in common use. It will be seen that the shape of the handle is the same as that of an ordinary screw, which is certainly the best adapted for getting the screw in quickly. For private houses there is no doubt but that this patent screw will be found exceedingly useful and convenient, but for public-houses and bars it is questionable whether the common plan of drawing corks will ever be departed from.

A STEAM OMNIBUS.

A SHORT time since a steam omnibus, or, to speak more accurately, an omnibus drawn by a road steamer, passed along Princes-street, Edinburgh. This road steamer has been built by Mr. R. V. Thomson for an enterprising omnibus proprietor in one of the largest towns of England, who intends to have his omnibus drawn by steam. The trial, says the "Scotsman," was divided into two stages, the first of them being at Granton. There the engine, with the omnibus attached to it, was run up and down the incline to exhibit its speed and the ease with which it could be controlled. It went up the hill at the rate of seven miles an hour and came down it at the rate of nine. It turned in the road with far greater ease than if drawn by horses, was pulled up instantaneously at the word of command, and even backed up hill. It then proceeded from Granton to Leith, and the second stage of the trial consisted in the journey from Leith to the West-end of Princes-street. The road-steamer, with its omnibus, started from Constitution-street, and ran at best omnibus speed up Leith-walk and Leith-street, making no account whatever of their steepness. The dexterity with which it picked its way between strings of cart-horses, omnibuses, and cabs, and the docility with which it stopped or turned whenever it was required, were marvellous. It ran from one end of Princes-street to the other without stopping, then turned down South Charlotte-street and on through North Charlotte-street to Forrest-street, where at the steepest point, when the descent looked really dangerous, it was brought to a sudden standstill, to show how completely it was under command, and how entirely it could dispense with any kind of brake. This was its final display, and it then went quietly and rapidly back to Leith. The trial was completely successful, and left nothing to be wished for. It was very amusing, as the road-steamer sped along Princes-street, to watch the pleased surprise depicted on every face as it passed. Those who saw it will be perhaps glad to remember that they witnessed the journey of the first steam-engine ever built for omnibus traffic in towns.

FRESH MEAT FROM THE RIVER PLATE.

AN experiment of importance towards solving the question as to the possibility of obtaining supplies of fresh meat from the practically boundless plains of the River Plate has been successfully completed. It was stated in the "Times" in April last that the Government of the Argentine Republic, and also the Government of Uruguay, had granted to an English house the exclusive privilege of shipping live cattle from those States for a period of years, with entire exemption from all port charges and Customs' duties, and that in the first instance a small trial would be made of the effect of the passage. It now appears that the steamer "City of Rio," which arrived recently, brought 19 oxen which had been shipped at Montevideo, and had been 31 days at sea, with, it is said, a short supply of water and scarcely any food but the commonest hay. No casualty had occurred among them, although from exposure and insufficient treatment they had become extremely thin. They were hurriedly shipped without selection on its being found that the vessel could take them, and the price paid at Montevideo was £5 per head, but a contractor at that port offers to supply any quantity at £4 per head, free on board, well prepared, and weighing not less than 800lb. each. It is also stated that the steamer by which these were brought had, on her outward passage, taken 15 English bulls to Montevideo consigned to Mr. Buschenthal, a large landowner, which arrived after a 37 days' passage (the distance being about 6,000 miles) not only all well, but, from careful treatment, in better condition than at the date of their embarkation. Of course these experiences furnish nothing decisive as to the commercial results to be looked for from the trade, but a steamer is now building expressly for carrying it on upon a large scale. This is expected to be ready in about six weeks, and will be followed by others of a similar character.

ELECTRIC BEACONS.

MR. THOMAS STEVENSON, C.E., Edinburgh, recently conducted an experiment at Granton with the view of showing the practicability of illuminating beacons and buoys at sea with the electric light, produced by means of a battery on shore. A submarine cable, fully half a mile in length, was laid between the east breakwater of Granton Harbour and the chain pier at Trinity. The operator occupied a station near the centre of the breakwater, and the light was shown at the point of the pier in front of an ordinary lighthouse reflector, producing a most brilliant flash. The flashes were emitted with great rapidity; as many as 500 can be transmitted in a minute, but the machine can be regulated so as to send one every second, or at any other desired interval. The experiment, which gave entire satisfaction, was conducted in the presence of Mr. Shaw Lefevre and Mr. Farrer, secretaries to the Board of Trade; Captains Fenwick and Nisbet, Elder Brethren of the Trinity House, &c.

TO CORRESPONDENTS.

THROUGH an error in the Printing Office, the headings of Mr. Walker's Coal-Getting Machine and Mr. Brierley's Machinery for Forging Nuts, which appeared in our issue of August 27, pages 154 and 155, were reversed.

THE MECHANICS' MAGAZINE is sent post-free to subscribers of £1 1s. 8d. yearly, or 10s. 10d. half-yearly payable in advance.

All literary communications should be addressed to the Editor of the MECHANICS' MAGAZINE. Letters relating to the advertising and publishing departments should be addressed to the publisher, Mr. R. Smiles, MECHANICS' MAGAZINE Office, 166, Fleet-street, London.

To insure insertion in the following number, advertisements should reach the office not later than 5 o'clock on Thursday evening.

We must absolutely decline attending to any communications unaccompanied by the name and address of the writer, not necessarily for insertion, but as a proof of good faith. ED. M. M.

Advertisements are inserted in the MECHANICS' MAGAZINE, at the rate of 6d. per line, or 5d. per line for 13 insertions, or 4d. per line for 26 insertions. Each line consists of about 10 words. Woodcuts are charged at the same rate as type. Special arrangements made for large advertisements.

G

Naval, Military, and Gunnery Items.

THE Lords Commissioners of the Admiralty have granted to the Bristol Training Ship Association the loan of Her Majesty's ship "Formidable," lately flagship at Sheerness, as a training ship for houseless and destitute boys, and Commander Edward Poulden, R.N., has been appointed captain superintendent. The "Formidable" is expected to arrive at Bristol in the course of next week.

DURING the month of August, 17 vessels, having a total tonnage of 16,599, were built on the Clyde. Of that number nine were built at Glasgow, four at Port-Glasgow, one at Greenock, one at Dumbarton, one at Renfrew, and one at Rutherglen. Nine were iron steamers, seven iron sailing ships, and one a composite. The largest of the 17 was the "Loch Katrine," 1,330 tons, intended for the Glasgow and Melbourne trade.

SOME time ago attention was drawn to the fact that the Shell Foundry Department, Royal Arsenal, Woolwich, was at a standstill for want of work, an order having been received to stop the making of Palliser projectiles, as they were found to break up in the gun when fired. This was supposed to have been caused by the studs being forced in by the explosive force of the powder. Since this the process has been tried of cooling the iron in sand. Several projectiles made in this way have lately been fired at Shoeburyness and found to answer most successfully, and it is to be hoped that the shell foundry will now resume its former activity.

A LETTER from Trieste says that the American frigate "Franklin," carrying the flag of Rear-Admiral Radford, is lying in that port. The Admiral, it is added, will go to Fiume to study the effects of our torpedoes. These engines, it may be said, *en passant*, make a great noise in the maritime world, and lately even the Prussians have convinced themselves of the efficacy of this new invention, originated by M. Lupis, a retired captain in the Austrian navy, and brought to perfection by Mr. Whitehead, an English engineer, proprietor of a machine manufactory at Fiume. The Americans are greatly interested in these torpedoes, and entertain a serious idea of making them the base, so to speak, of naval warfare, not only for defence, but for attack.—"Army and Navy Gazette."

DR. PETERMAN has received a first letter from the German Expedition to the North Pole, containing intelligence to July 29. Contrary winds and storms had detained the expedition until July in the North Sea, and forced it to keep near the coast of Norway. The first ice was encountered on July 12, lat. 74 N., long. 10 W. Up to July 29 the expedition had not reached the coast of Greenland, which was, however, in sight. At 25 German miles from the coast the soundings showed a depth of 7,000ft. Captain Koldeway reports that the position of affairs is very different from that met with in 1868. The temperature is higher, the winds more constant, and the ice looser, but from July 9 to 29 much foggy weather prevailed. The ship is in excellent condition, and the crew in good health.

IT is now confidently asserted that in addition to closing Woolwich and Deptford dockyards, the Government has decided on the abolition of Sheerness as a naval establishment as soon as the requisite arrangements connected with the change can be carried out. The only dockyards and naval establishments which will thus be retained are those at Chatham, Portsmouth, Devonport, and Pembroke. The Government, by the abolition of Woolwich, Deptford, and Sheerness dockyards, only give effect to the recommendation of the Committee which sat some since, in concentrating the whole of the naval resources of the kingdom at some three or four large dockyards. For some years past Sheerness has been allowed to sink into the position of one of the minor dockyards, the large establishment at Chatham, some few miles higher up the Medway, monopolising nearly the whole of the building and fitting of the ships of our ironclad squadrons, while the completion of the vast basins and docks now in course of formation at that port will leave no necessity for the retention of Sheerness as a separate naval establishment. As to the use to which Sheerness dockyard may ultimately be put, nothing definite would appear to be decided; but it seems probable that it will be retained as a place for depositing naval stores. The period for closing the dockyard at Woolwich is fixed for the 1st of October, when the whole of the mechanics and other hands employed at the establishment will be discharged. Already a number of the established workmen have been transferred to Chatham Dockyard, and the remainder will be sent to that and other dockyards as vacancies occur at those establishments.—"Pall Mall Gazette."

THE prevailing belief that iron ships cannot be built in the United States, owing to the dearness of iron and the high rate of wages under the protective system, is stoutly denied by the "Wilmington Commercial" (Delaware), which gives the following information on the subject:—This city, as is well known, is the head quarters of iron shipbuilding in this country. Our construction of wooden ships has declined in importance, as it has everywhere; but since the difficulties alleged to exist are those of foreign trades, for which iron vessels are largely used, we may confine our inquiry to the latter class. In iron ships, then, our builders have recently competed directly with the builders on the Clyde, and, having put in a lower estimate, have received work in preference to those celebrated English artisans. The case in point was the construction of a seagoing iron steamship for the Central American trade, built at the order of the Panama Railway Company. The proposal of the Wilmington firm being less than the Clyde builders, the ship was built there. It is needless to say that the work was as well done in all respects and the material as good as it could have been if constructed in Great Britain; but it is proper to add that new contracts at rates similar will be accepted by our builders. In another case another of our firms has built two steamers, and is now at work on a third for a company who run lines on some of the South American rivers. For various reasons our builders are preferred after a direct comparison of their abilities with those of the English builders, and the company in question gave them the work. So decided, indeed, is the conviction of the leading firms of this city on this question, that on being recently applied to by a proposed ocean steam-ship company for a certificate to be presented to Congress, that on account of the tariffs on ships' materials, it was impossible to furnish vessels at foreign prices, and that, therefore, those duties should be repealed, they conscientiously refused to make any such statement, for the simple reason that they knew it to be incorrect—this, too, notwithstanding that the statement had already been signed by leading firms in New York and Boston. These, we think, are important facts.

Miscellanea.

THE money remitted to the Chancellor of the Exchequer by sundry persons for conscience' sake in the financial year ending March, 1869, amounted to £4,194. In the preceding year the amount was £4,688. We understand the working expenses of the Chancellor of the Exchequer's Office are annually met by the receipt of conscience money.

THE new act (32 and 33 Vic., cap. 17), for the preservation of sea birds, states that the sea birds of the United Kingdom have of late years greatly decreased in number, and that it is expedient to provide for their protection during the breeding season. It is made an offence to kill, wound, or to take or have possession of any sea bird recently killed or taken between April 1 and August 1 in each year, one moiety of the penalty of 20s. to be paid to the informer.

THE number of visitors to the South Kensington Museum during the week ending September 4, 1869, was—on Monday, Tuesday, and Saturday (free), from 10 a.m. to 10 p.m., 15,323; Meyrick and other galleries, 2,720; on Wednesday, Thursday, and Friday (admission 6d.), from 10 a.m. till 6 p.m., 2,114; Meyrick and other galleries, 236; total, 20,393. Average of corresponding week in former years, 12,000. Total from opening of Museum, 8,774,006.

HIS ROYAL HIGHNESS the PRINCE of WALES has granted two scholarships to the Royal School of Mines, which is under the directorship of Sir Roderick Murchison, and several others have been established by the Government. In the ensuing session, which commences on the 4th prox., the following courses of lectures and demonstrations will be given:—1, Chemistry, by Professor Frankland, Ph. D., F.R.S.; 2, Metallurgy, by John Percy, M.D., F.R.S.; 3, Natural History, by Professor Huxley, LL.B., F.R.S.; 4 and 5, Mineralogy and Mining, by Mr. Warrington Smyth, M.A., F.R.S.; 6, Geology, by Mr. A. C. Ramsay, LL.D., F.R.S.; 7, Applied Mechanics, by Mr. T. M. Goodeve, M.A.; and 8, Physics, by Mr. F. Guthrie, B.A., Ph. D.

THE return showing the import of gold and silver bullion and specie registered at the Custom-house states an arrival of gold from Australia in the month of July amounting to no less than £1,201,626. Mexico and South America also sent gold and silver of the value of £732,000, and the United States as large an amount. The import of gold and silver into the United kingdom this year, which up to the end of June had only reached £9,375,934, had been raised to £12,522,316 at the end of July. The export of gold and silver from the United Kingdom in the month of July did not reach a million. The whole seven months' export was £9,975,899. £4,525,424 went to France and £2,488,475 to Egypt, the high road to other parts ever athirst for gold and silver.

CONSIDERABLE alterations are now being made in the New Palace of Westminster, within the central hall and the interior approaches to the Houses of Lords and Commons, the object being to afford more natural light. For this purpose, the stained glass windows in the Peers' corridor have already been transformed into plain glass designs. It was intended that the stained glass windows in the central hall should also be discoloured, but this idea has been abandoned for the present. A large number of workmen in the employ of Messrs. Field, of Parliament-street, the contractors, are now busily engaged in removing the moulded archways, which will now be rendered comparatively, if not altogether, useless. In place of them, temporary glass screens will be erected. The whole of this expenditure is undertaken for the purpose of affording more light at the entrances to the interior of both Houses of Parliament.

AN Act of Parliament was passed in the late Session to make provision respecting the use of subways under the management of the Commissioners of Sewers of the city of London. It recites that subways are in the course of construction under the viaduct or raised way and parts of the new street in the city of London, and the same, when completed, will be under the Commissioners of Sewers, and in order to prevent inconvenience to the public and the frequent breaking up of the surface of the viaduct and new streets, the Commissioners should be enabled to require companies, bodies, and persons intending or required to place water, gas, or other pipes, to lay them in the subway, on proper terms and conditions. The Act invests the Commissioners with power to carry out the provisions, and provides remedies against parties violating the terms and conditions annexed to the undertakings. The Commissioners, as far as space will permit, and without favour or preference, are to allow pipes to be laid in any subway under their management. The Commissioners are to exercise supervision, and the subways are to be maintained in an efficient state of ventilation, and in case of difference the Board of Trade is empowered to give directions on the subject. A penalty of £20 may be recovered for an infraction of the provisions, and the Commissioners may remove pipes, &c., improperly laid down, and recover the expenses as a penalty.

ON the 9th ult. an Act to alter and amend the Telegraph Act of 1868 received the Royal assent, and arrangements are being made, and are expected shortly to be perfected, to transfer the telegraphs to the Postmaster-General. By the new Act the Treasury is empowered to raise £7,000,000. The gross revenue received by the Postmaster-General for the transmission of messages by means of electric telegraphs is to be paid into the Exchequer to the account of the Consolidated Fund, and the expenses incurred with the sanction of the Commissioners of her Majesty's Treasury in working, maintaining, or extending telegraphs to be paid out of moneys to be voted by Parliament. By the recited Act (31 and 32 Vict., cap. 110) the Postmaster-General was empowered to purchase the whole or part of the undertaking of any telegraph company except the Atlantic Telegraph Company and the Anglo-American Telegraph Company. The Postmaster-General was required by the former Act to make one uniform charge for the transmission of telegraphic messages throughout the United Kingdom, and it is declared in the present statute that in order to protect the public revenue it is expedient that similar powers to those conferred upon the Postmaster-General with respect to the exclusive privilege of conveying letters should be enacted with reference to the transmission of public telegraphic messages within the United Kingdom. Agreements have been made with certain telegraph companies to pay them £5,715,048 8s. 11d., and it is estimated that the amount which will be required for the other purposes of the recited Act and of the new Act will not exceed £300,000, besides £700,000 with railway companies, and the chief object of the present Act is to give authority to the Commissioners of the Treasury to raise the funds which will be required to enable the Postmaster-General to carry into effect the arrangements. There are a few exceptions mentioned to the exclusive privilege of the Postmaster-General sending telegraphic messages, and he is also empowered to transmit foreign messages. The Treasury may raise sums not exceeding £7,000,000, for the purposes of the Act, either by terminable annuities or by the creation of Exchequer bills or bonds, and the moneys raised are to be placed at the disposal of the Postmaster-General under certain regulations. Annual accounts are to be laid before Parliament, as also the regulations made under the new Act. No deed or instrument executed by, to, or with the Postmaster-General is to be liable to stamp duty. Messages are to be deemed post letters, and the provisions of the Telegraph Acts of last year and the present year to be considered as "Post-office laws."

Patents for Inventions.

ABRIDGED SPECIFICATIONS OF PATENTS.

THE Abridged Specifications of Patents given below are classified, according to the subject to which the respective inventions refer, in the following table. By the system of classification adopted, the numerical and chronological order of the specifications is preserved and combined with all the advantages of a division into classes. It should be understood that these abridgments are prepared exclusively for this Magazine from official copies supplied by the Government, and are, therefore, the property of the Proprietors of this Magazine. Other papers are hereby warned not to produce them without an acknowledgment:—

BOILERS AND FURNACES—402, 422, 476
BUILDINGS AND BUILDING MATERIALS—423, 439, 448, 453, 472
CHEMISTRY AND PHOTOGRAPHY—417
CULTIVATION OF THE SOIL, including agricultural implements and machines—431, 437, 450, 452, 479
ELECTRICAL APPARATUS—None
FIBROUS FABRICS, including machinery for treating fibre pulp, paper, &c.—404, 408, 409, 410, 420, 438, 458, 461, 464, 469
FOOD AND BEVERAGES, including the apparatus for preparing food for men and animals—414, 434
FURNITURE AND APPAREL, including household utensils, time-keepers, jewellery, musical instruments, &c.—412, 415, 427, 430, 433, 436, 363, 467, 474
GENERAL MACHINERY—411, 453, 456, 471, 479
LIGHTING, HEATING, AND VENTILATING—403, 428, 444, 449, 461
METALS, including apparatus for their manufacture—426, 457
MISCELLANEOUS—407, 413, 416, 418, 419, 429, 432, 445, 447, 460, 465, 466, 473, 477
ROADS AND VEHICLES, including railway plant and carriages, saddlery, and harness, &c.—406, 424, 425, 435, 441, 454, 457, 459, 475, 478
SHIPS AND BOATS, including their fittings—425, 440
STEAM ENGINES—405, 443
WARFARE—442, 446, 462

---

402 B. F. STURTEVANT, Massachusetts, U.S. *Furnace blower.* Dated February 9, 1869.
This consists in a corrugated case or multi-duct surrounding the periphery and one side of the blast-wheel case, and serving both to conduct the air from the peripheral educts of such case to an eduction pipe or conduct, and to prevent it, to a considerable extent if not entirely, from whirling or revolving while passing into the eduction pipe.—Patent abandoned.

403 J. H. JOHNSON, Lincoln's Inn-fields. *Heating and ventilating.* (A communication.) Dated February 9, 1869.
The radiator and ventilator is so constructed that a thin stratum or column of steam is exposed on two sides to the external air intended to be heated, the combined area of the surface of these two sides being much greater than the exposed surface of the radiators now commonly in use. The steam has a direct passage through the radiator, and as it does not follow a tortuous course its movement is rapid and the whole interior is quickly filled, condensation takes place rapidly and induces a swift current of the external air through the heated central tubes.—Patent completed.

404 J. H. JOHNSON, Lincoln's Inn-fields. *Manufacture of paper.* (A communication.) Dated February 9, 1869.
The pulp being contained in the beating engine either the solution of the salts of lime, magnesia, baryta, or strontia, their chlorides, for example, are to be first added, and then the decomposing solution, such as the sulphate or silicate or carbonate of soda in about equivalent proportions, are to be added until the desired precipitation has been effected, or the sulphates, carbonates, or silicates may be first added and then the alkaline earthy solutions. It will be understood that when it is desired to obtain the precipitation of an insoluble sulphate, such, for example, as sulphate of baryta, either sulphuric acid or a soluble sulphate may be employed in conjunction with a soluble salt of barium, such, for example, as the chloride of barium. When an insoluble carbonate such as the carbonate of baryta is used, a soluble carbonate in conjunction with a soluble salt of barium is employed. When an insoluble silicate is used then a soluble silicate in conjunction with a soluble salt of barium is employed, and so in like manner for the formation of the insoluble compounds of the other substances referred to.—Patent abandoned.

405 E. J. A. CAMERE, Nice. *Rotary steam engines.* Dated February 9, 1869.
This engine consists of a perfectly bored cylinder of a diameter and thickness varying with the power of the machine. This cylinder, closed at its two ends by solid plates provided with tightening bolts and stuffing box gland, carries laterally two flanges or rings pierced with longitudinal ports intended to receive in the case of a steam or of a water motor the induction and the eduction pipe, and in the case of pumps and fans the suction and force pipes.—Patent abandoned.

406 K. B. EDWARDS, Claverton-street. *Communicating in trains.* Dated February 10, 1869.
The inventor employs the agency of an explosive compound or other force whereby a ball or other body may be thrown or ejected from one carriage to another as a means of communication between different portions of a train. A shot or explosive apparatus is to be used in conjunction with a chain or cord communicating with each of the several compartments into which any carriage may be divided for the purpose of enabling the occupants in any portion of the train to communicate with the guard or driver by pulling such chain or cord.—Patent abandoned.

407 G. GROS, Bordeaux, France. *Self-closing boxes.* Dated February 10, 1869.
These boxes are formed with two cases or shells of a rectangular shape, but rounded off at each end. The deeper one is the receptacle, and the flatter one the lid. The straight edges of both parts are formed so as to enter and slide in one another. They are tied to each other either by means of a small steel or wire spring, or by a thin strip of india-rubber acting as a spring, and keeping them closed. The box can be opened very easily by sliding the lid with the thumb of the hand in which the box is held. On the pressure of the thumb being removed, the lid instantly slides back and closes the box, this being effected by the action of the small spring lodged inside, but which might equally well be placed outside; and, instead of a single spring, two might be used, one on each side. That part of the top of the lid against which the thumb is to bear slightly, in order to open the box, is clearly indicated by the exergue, or the obligatory inscription of any patented article, the under side of the box being either pointed, cut in the casting, or in any way roughened to give a rubbing surface on which to ignite the matches.—Patent completed.

408 W. HILTON, Bolton. *Looms.* Dated February 10, 1869.
This relates, first, to the picking sticks of what are commonly known as "under pick" looms, and consists in an arrangement of mechanism for returning the picking stick to its normal vertical position after each pick. The invention relates, second, to the "swells" of the shuttle boxes, and consists of an arrangement for controlling the action of the "swells" in such a way that the shuttle is relieved from the pressure thereof immediately before and during each pick, the "swells" coming into action again before the shuttle reaches the opposite box.—Patent completed.

409 J. CROFTS, Leeds. *Combing wool.* Dated February 10, 1869.
This invention is intended to facilitate the removal of the noil produced by the operation of combing. For this purpose, when the noil has lifted up the teeth of the combs by means of the noil lifters, the inventor causes a current of air flowing from the mouth of a tube or other suitable channel, and supplied from a fan or otherwise, to act on the lifted noil and blow it direct, or by a suitable channel, into a can or receiver.—Patent abandoned.

410 J. STUART, Limehouse. *Separating vegetable from animal fibres.* Dated February 10, 1869.
This relates to mixed fabrics or fabrics composed partly of animal and partly of vegetable fibres, and has for its objects—first, the separation of animal fibres (such as, for example, wool, hair, or silk) from the vegetable fibres, such as cotton, flax, jute, or other vegetable fibre; and, second, the effecting of this separation in such manner that the animal fibre is obtained uninjured either in substance or quality, and, in a great measure also, in colour.—Patent completed.

411 S. MELLOR, Park-terrace, Victoria Park. *Pumps.* Dated February 10, 1869.
The inventor forms the barrel of the pump of a tube of any suitable elastic or flexible material. Within a casing, semicircular at the upper part, the inventor adapts a piece of elastic tubing, which passes through holes formed through the rim of the casing, one hole being formed through one side of the rim, a little above the springing of the semicircular part thereof, and the other hole through the opposite side of the rim a little below the springing of the semicircular part thereof, so that when the tube is passed through the holes it follows the curvature of the inside of the curved part of the casing. Through the sides of the casing, and at the centre from which the semicircular part is described, the inventor forms holes and adapts a short horizontal shaft or axle working in suitable bearings, and on the shaft or axle he fixes a piece of metal carrying two rollers mounted therein at opposite sides of the shaft, and in a line with the centre thereof.—Patent abandoned.

412 W. LEVER, Union-street, Borough. *Hats.* Dated February 10, 1869.
This consists in manufacturing the body of a certain combination of materials not hitherto used for the purpose. For this object a sheet, layer, or piece of thin caoutchouc or gutta-percha, or of waterproof material whereof caoutchouc or gutta-percha is an essential or main constituent, is placed or interposed between two pieces, layers, or thicknesses of cotton or other textile, woven, or knitted fabric. The three thicknesses, layers, or pieces are then all cemented or caused to adhere together firmly and substantially by the employment of shellac or other gummy, gum resinous, resinous ordinary, or adhesive substance, which also imparts considerable stiffness to the compound material.—Patent completed.

413 S. W. MULLONEY, Coventry. *Surgical bandages.* Dated February 10, 1869.
This invention consists in making, during the process of weaving the bandage a series of what are known to manufacturers of ornamental goods as continuous "purls" or loops along each edge of the bandage, instead of forming, as heretofore, a rigid or inelastic selvage, and thus giving the edge an elasticity equal to that of the centre of the fabric.—Patent abandoned.

414 C. T. E. LASCELLES, Southwark. *Machine-made casks.* Dated February 10, 1869.
This relates to the manufacture of casks by the aid of machinery, the object being to facilitate the cutting of the staves of casks and to produce joints akin to those which are found only in hand-made casks. This is effected by the use of a machine which contains a pair of rotary cutters set in a vertical plane so that they may be adjusted to suit different widths of stave, and capable of varying the bevel of their cut, as desired.—Patent completed.

415 F. J. KNEWSTUB, St. James's-street, Westminster. *Locks and fastenings for bags.* Dated February 10, 1869.
This consists in making the nozzle and face plate apart from the plate which is secured to the bag, and connecting this plate to the nozzle in such a manner that it is free to be turned or otherwise moved in order to release the hasp, or the nozzle may be connected to or form part of the plate which is secured to the bag, and the face plate which operates the lock may be secured to the first-named plate in any suitable manner; by turning, moving on one side, or otherwise operating this plate the hasp is released.—Patent abandoned.

416 J. F. BENTLEY, Peterborough. *Filters.* Dated February 10, 1869.
This consists in the adaptation to filters of a closed reserve tank or vessel to contain the filtered water after it has passed through a layer or layers of filtering material, so that on the application of a pump or syphon or a tap, by which it is intended to draw the water from this reserve tank or inner cylinder, and on the removal of all or a portion of the water from the tank or cylinder, a partial vacuum will be formed, in consequence of which the process of infiltration will continue with regularity, though the withdrawal of water from the reserve tank may be sudden, intermittent, and irregular.—Patent completed.

417 W. H. FISCHER, Manchester. *Photographic printing process.* Dated February 10, 1869.
The inventor dissolves gelatine and gum arabic in the proportions of about 30 grains of gelatine and 10 grains of gum arabic in 1oz. of water, and adds thereto about five grains of lump sugar. After filtering he adds one drachm of a saturated solution of bichrome of potass or bichrome of ammonia. The mixture is then ready to pour on the glass, slate, or metal which is to form the positive picture. After drying the plate so prepared is placed under the negative so that the film side of the negative shall be in contact with the gelatine film.—Patent abandoned.

418 G. BROADHURST and J. KERSHAW, Manchester. *India-rubber cloths.* Dated February 10, 1869.
The inventors prepare a compound of caoutchouc and golden sulphuret of antimony, commonly called the red or mineralized caoutchouc or india-rubber, and spread layers of it on and between cloths in the usual way, preferring this compound to that which has hitherto been used on account of its extraordinary grease-resisting qualities, while it is well known that the ordinary grey vulcanised india-rubber very soon decomposes when in contact with articles containing even very minute portions of oil or grease, and in addition, double texture cloths thus made are not liable to harden in cold temperatures, as is the case with what is known as the natural rubber card cloth now in use.—Patent completed.

419 P. TAYSEN, Leith. *Manufacture of stearic acid.* (A communication.) Dated February 10, 1869.
When the inventor has completed the decomposition of the fatty acids, which now have a melting point of 48deg. to 50deg. celsius, and which are black or dark, he lets them rest from 12 to 16 hours. During this time a part of the black substances are precipitated into the sulpho-glycerine water, and are driven off along with it by a cock situated at the bottom of the vessel. After this, the fatty acids are removed to another vessel, which vessel is provided with two leaden tubes for steam, one open, and allowing the steam to escape into the material, the other closed. In this vessel the inventor makes the fatty acids boil partly by free steam and partly by the closed steam pipe, and during the boiling and while continuing agitation, he adds an energetic oxidising agent.—Patent completed.

420 J. CLAYTON, Radcliffe. *Fixing paste for prints.* Dated February 10, 1869.
The inventor first boils 4lb. of kid glue in 2½ gallons of water till dissolved, stirring it well all the time. When boiled down to about 2 gallons, he adds thereto 2 gallons of turpentine, and boils again. He then cools down to about 110deg. Fah., and adds 4 gallons of blood albumen at a strength of about 3lb. per gallon, previously dissolved in either water, buttermilk, or blood, mixes well, and stirs for about four hours. To prepare for use he takes 1 gallon of the above preparation and mixes therewith an equal quantity of blood albumen solution (at a strength of about 1½lb. to the gallon), and to this mixture he adds the aniline or other colour as required.—Patent completed.

421 Not allowed. Abstract will appear in a future number.

422 J. A. F. SUTER and T. C. HINDE, Hereford. *Heating boilers.* Dated February 10, 1869.
This consists in producing a gaseous fluid by directing atmospheric air upon or through ignited coal or coke, or other solid fuel, in an oven or chamber, the atmospheric air being forced over or through the ignited fuel by means of a fan or other blowing machine or apparatus. There is thus produced a gaseous fuel consisting essentially of carbonic oxide mixed with nitrogen. This gaseous fuel is conducted to the furnace or fireplace of the boiler and mixed with atmospheric air, and upon being ignited heats the boiler and generates steam in the said boiler. By the use of a blast of air obtained by a fan or other blowing machine or apparatus, complete control is obtained over the production of the gaseous fuel, which cannot be obtained when the draught of a chimney or stack is employed to determine the current of atmospheric air through or over the solid fuel.—Patent completed.

423 J. CARTER, Birmingham. *Waterclosets.* Dated February 10, 1869.
Underneath the ordinary basin, with its movable bottom or pan, the inventor places a second basin having a movable bottom or pan, which is brought into its raised position by a counterbalance weight or spring. The axis of the movable bottom of the second or lower basin is so connected by a chain or otherwise with the axis of the movable bottom of the upper or ordinary basin that the raising of the movable bottom of the upper or ordinary basin causes the depressing of the movable bottom of the lower basin.—Patent completed.

424 J. E. BILLUPS, Cardiff, and W. COOPER, Rotherhithe. *Communicating in trains.* Dated February 10, 1869.
This consists of a friction or cam wheel or other kind of wheel or wheels, either fixed upon the axle or held in contact with the carriage wheel or wheels, or rail, and acting upon a gong, whistle, ratchet and click, or other instrument or apparatus for producing sound, by which means each carriage, when in motion, is provided with a complete method of signalling between the passengers and the guards and engine drivers without necessitating any special connection between the several carriages.—Patent abandoned.

425 W. R. LAKE, Southampton-buildings, Chancery-lane. *Water velocipede.* (A communication.) Dated February 10, 1869.
This apparatus is constructed with two, three, or more insubmergible boats or floating parts which may be formed of any suitable material. These boats are arranged side by side, and at a sufficient distance apart to allow the paddlewheel or wheels to be placed between them, and are connected by crossbars. The paddlewheels are operated by treadles similar to those of land velocipedes, and the desired direction is given to the apparatus by a rudder which is controlled by a chain wheel according to the "Vaucanson" or other system.—Patent completed.

426 G. F. ANSELL, Bernard-street, W.C. *Manufacture of steel, &c.* Dated February 11, 1869.
This relates to the conversion of cast iron into steel or into wrought iron, by the use of bisulphate of potash, or bisulphate of soda, or a mixture of the two to act upon the metal in a molten state, and applied in such a manner as to act throughout the mass of melted metal. For

this purpose, the bisulphate may be placed at the bottom of a vessel lined with fire-clay, which may be called the converting chamber or receiver, and the melted cast iron poured upon it. This converting chamber may also have ridges or ledges ranged round its interior, upon which the bisulphate may also be placed, or it may be placed in layers between thin plates of cast iron or in recesses in the bottom of the converting chamber.—Patent abandoned.

427 P. J. SMITH, F. W. SMITH, H. J. SMITH, and A. PAPPENBERGER, all of Bristol. *Pianofortes.* Dated February 11, 1869.

The inventors employ one or more metal bars or studs which pass underneath the soundboard, and at the ends are cranked or bent up, so as to rise above the surface of the soundboard, and take a direct bearing against a metal bar laid in the wrest plank at the one end and against the bass plate and bent side (or plate covering the same) at the other end. Thus, these bars or studs, while they do not in any way interfere with the strings and action, directly take the strain between the wrest plank and base plate and bent side, thereby preventing any pulling over of these parts and all leverage upon the back (or bracings) of the instrument, and enabling strings of the same weight and tension to be used in upright pianos as have hitherto been used in grand pianos.—Patent completed.

428 G. A. NOWELL, Nuneaton. *Lamps.* Dated February 11, 1869.

When using an argand burner, the following is the arrangement the inventor prefers to employ:—At the lower part of the lamp the reservoir for the hydro-carbon oil is formed (it may be of globular or other convenient form), and the gas pipe (which has a suitable regulating cock upon it) passes up vertically through the reservoir, and ascends nearly to the top of the heated chamber, which is a cylinder closed at its upper end, and at its lower connected with the top of the reservoir; a wick (which it is preferred to make of cotton wool enclosed in wire gauze) surrounds the ascending gas tube, and can be moved up and down on it by turning a milled head on the exterior of the lamp, so as to regulate the amount of wick within the heated chamber, and, consequently, the amount of vapour formed. The gas passing up its pipe to the top of the heated chamber, there enters the chamber and descending mixes with the hydro-carbon vapour, and the compound passes out near the bottom of the chamber to the ring burner, where it is burnt. This burner encircles the chamber, so that when the burner is lighted, the upper part of the chamber will be surrounded by the flame, and will thereby become intensely heated.—Patent completed.

429 J. YOUNG, Limefield. N.B. *Measuring pressure of gases.* Dated February 11, 1869.

To measure the pressure of gases and the force of aeriform or gaseous currents, a U-tube containing water in both limbs is often used. The inventor puts a cistern or overflow on one or both arms of the tube, and uses two liquids of different densities, by which means he increases the sensitiveness of the instrument in proportion as the liquids approach each other in density.—Patent abandoned.

430 H. P. HANSEN, Leith. *Stoves.* Dated February 11, 1869.

The fire-chamber is lined with firebrick, and the unburnt gases and smoke given off by the fuel during combustion ascend through chambers situated above the fire-chamber in a zigzag direction in passing to the smoke pipe or chimney. This is effected by dividing the stove into separate chambers (which may be of any desired number) by horizontal divisions or dampers, openings being left in these alternately at opposite sides of the stove, so that as the unburnt gases and smoke produced during combustion ascend, they enter each chamber at one side and escape into the chamber above at the opposite side.—Patent abandoned.

431 C. THOMAS, Bristol. *Reaping machines.* (A communication). Dated February 11, 1869.

The rake makes its effective sweep across the platform from the grain side of the same toward the main frame. The grain is thus gavelled or bundled at the inner edge of the platform, and is held by the rake, which has an interval of rest for that purpose, against a wire which is supplied from an elevated reel, and held by grasping devices at a point below the gavel. The wire is made to completely encircle the gavel by the descent of a binding arm, and a length is cut off and twisted, so as to firmly and securely bind the grain into a sheaf.—Patent completed.

432 B. P. STOCKMAN, Abingdon-street, Westminster. *Meters for water.* Dated February 11, 1869.

This consists of two cylinders and pistons combined and working with a reciprocating action, viz., one piston up while the other is down. The two cylinders are placed side by side on a base plate common to both. The cylinders are bored out, and the pistons are packed with a cupped leather or with any other suitable packing to ensure their working watertight, or the means of rendering them watertight may be bags of leather or india-rubber attached at one end to the cylinder and at the other to the piston; when this method is adopted it may not be necessary to bore out the cylinders. At the top of the cylinders there is a capping plate, upon which is seated the whole system of gearing comprising the valve apparatus. Each piston has a toothed rack attached to it in place of a piston rod, and the two racks pass through holes provided for the purpose in the capping plate. Between the two racks is a toothed wheel in gear with both, which gives the reciprocating action to the piston. A four-way valve is fixed on the capping plate centrally with the toothed wheel, and from two of the openings in the valve, there is a communication with the bottom of the cylinders by means of pipes or passages cast in the cylinders, while the two other openings in the valve have the supply and discharge pipes attached to them.—Patent completed.

433 A. C. ENGERT, Tabernacle-row. *Mouldings for picture frames.* Dated February 11, 1869.

The inventor causes two suitable pieces of wood fashioned to the general form of the moulding which it is desired to produce to pass under a vessel containing composition, and as the wood passes under the vessel the composition is pressed out through an orifice in a thin sheet which is caused to adhere to the wood by means of size, which is applied to the wood just before the sheet of composition comes in contact with it. Then as the wood is made to travel on in the machine the composition is pressed down upon its surface by a roller with a smooth face and corresponding in form with the moulding; in this way a smooth, or comparatively smooth, surface is obtained. Then the wood with the composition upon it is, if necessary, passed through a die, which completes the smoothing, cutting off, and rubbing down any inequalities that may remain on the surface. To produce a pattern on the moulding it is now passed under a roller on which the pattern is cut, and in this way the pattern is impressed on the composition. Usually the pattern will not extend over the whole width of the moulding, and then the parts which do not receive the pattern remain smooth as they were left by the roller and die.—Patent abandoned.

434 H. EDWARDS, Staple Inn, Holborn. *Preserved food* Dated February 12, 1869.

The inventor takes potatoes, or other vegetable substances, in a natural or cooked state, or other articles of a similar nature, and mixes them with meat or other fleshy substances in a concentrated state. The natural potato or other vegetable, when thus mixed with meat or other fleshy substances, essence, or extract therefrom, becomes impregnated and retains the flavour and the nutriment of the said articles. He then brings it into a granulated or finely divided state, and dries it at a regulated temperature. When in this state it can be packed in tin or other cases, and, if kept dry, presents in any climate a valuable and portable article of diet.—Patent completed.

435 W. J. HORTON, Warrington. *Railway chairs.* Dated February 12, 1869.

This consists in an improved mode of holding the rail in the chair, and it consists in applying a cast-iron wedge between the rail and the chair in place of the usual wooden key or wedge. The inventor employs a wrought-iron key inserted from above between the chair and the cast-iron wedge to hold the latter firmly against the rail. This cast-iron wedge is made of such a form that its lower edge sets against the flange of the rail which is in the chair, and by means of the wrought-iron key the cast-iron wedge is held in contact with the side and also the flange of the rail in the chair.—Patent completed.

436 T. A. COLLINSON, Liverpool. *Boots.* Dated February 12, 1869.

The operator should first provide himself with an ordinary block for stretching and forming to the required shape the upper leather, to which is fitted on the edge or front, from the fore part of the instep up to the top of the leg piece, a movable ridge piece of sufficient width and length to require sufficient extra upper leather to form the flap piece in which the button holes are to be worked. —Patent abandoned.

437 F. J. VANDENVINNE, Brussels. *Working ploughs.* Dated February 12, 1869.

This refers to previous letters patent dated the 28th day of May, 1867 (No. 1573), and the invention consists in an endless railway so attached to the machine that the wheels rest thereon. This railway, by the motion of the machine forward or backward and suitable articulated joints therein, is caused to be laid continuously under the wheels so as to prevent them from being imbedded in the earth by the great weight of the machine or from being impaired by stones or other matter.—Patent completed.

438 W. H. HAYHURST, Blackburn. *Looms.* Dated February 12, 1869.

This relates to means and apparatus for stopping the loom when from any cause one or more threads of warp are broken. This is effected by means of two brackets fixed to the breast-beam of the loom, one being near the weft fork and hammer, the other on the other side of the loom. The brackets are connected by means of a rod along which two or more "warp forks" are caused to pass "to and fro" across the piece by means of a cord attached to the warp forks passing over pulleys on the brackets above mentioned and a weight which is attached to the cord.—Patent completed.

439 H. B. BINKO, Cleveland-road, Islington. *Colouring matters.* Dated February 12, 1869.

The inventor takes indigo of the best quality and after it has been finely ground and sifted he dissolves it in acid in the proportion of 3lb. of acid to 1lb. of indigo, and allows the mixture to stand for three days. After this the inventor adds to every pound of the above indigo 20lb. of water and 5lb. of goat or cow hair, boiling the whole three hours, or until it becomes of a greenish hue; this is then allowed to remain 24 hours standing. The hair is then taken out, and washed in clear cold water until a beautiful blue colour appears. He then puts the hair into 10 gallons of water, and boils it, and whilst boiling adds potash in the proportion of 10lb. of potash to 1lb. of indigo, thus rendering the indigo solution free from acid. The whole is then strained and evaporated to half its bulk, and allowed to remain 36 hours standing.—Patent completed.

440 T. V. TREW, Stratford. *Screw propellers.* Dated February 12, 1869.

This consists in constructing screw propellers in a form which is a combination of a curved face or propelling surface and a spiral leading edge.—Patent completed.

441 G. H. MORGAN, Edgware-road. *Carriages.* Dated February 12, 1869.

The inventor mounts an axle or shaft in suitable bearings carried by the quarter of the carriage, and applies at each end thereof an arm which by a link or connecting rod is attached to a projection from the head pillar. A projection from each of these links or connecting rods is by another link or connecting rod attached to a projection carried by the "cant rail" or by the hinge thereof. To each of the levers the inventor connects one end of a spring the other end of which is connected to the standing pillar or to other suitable part of the carriage body.—Patent completed.

442 W. E. NEWTON, Chancery-lane. *Explosives.* (A communication.) Dated February 12, 1869.

This consists in the combination of nitro-glycerine with any suitable nitrate and carbon so as to form an explosive compound differing in character from ordinary gunpowder. When a powdered nitrate, whether it be a nitrate of potash, soda, baryta, or lead, is intimately mixed with coal or any substance containing carbon or hydrocarbon, such as rosin, sugar, or starch, a combustible mixture is produced, which, unless enclosed or confined under strong resistance, burns too slowly to form what is usually called an explosive mixture. But a slight addition of nitro-glycerine, intimately mixed therewith so as to form a thin coating over every separate grain, admits of effecting the instantaneous combustion of the whole, owing to the intense heat developed by the explosion in immediate contact with every grain of nitre, which it causes to melt.—Patent completed.

443 A. V. NEWTON, Chancery-lane. *Rotary engine.* (A communication.) Dated February 12, 1869.

The case or cylinder (the interior of which is oblong in the transverse direction) is fitted with a rotary piston block, carrying at its periphery hinged leaves or pistons to receive the pressure of the impelling fluid. This piston is keyed fast to the central shaft, which has its bearings in the heads or cover of the case or cylinder. But these covers, besides serving to close the ends of the case, also provide (as will hereafter be fully explained) steam supply passages and exhaust chambers for the engine.—Patent completed.

444 F. C. HILLS, Deptford. *Gas retorts.* Dated February 12, 1869.

This relates to previous letters patent dated April 29, 1864 (No. 1087). The inventor introduces into the closed ashpit of the furnace air heated by the waste heated gaseous products of combustion, but he tempers the heat generated by this air by mixing therewith a portion of the waste heated gaseous products of combustion which escape from the furnace through the flue to the chimney. The carbonic acid and nitrogen contained in these products when mixed with the atmospheric air introduced into the furnace diminish the intense local heat which heated air generates when introduced by itself, and the heat is by this means the better diffused through the bed of retorts, and a saving of fuel is effected.—Patent completed

445 W. SUMMERS, Bristol. *Packing cases.* Dated February 12, 1869.

The inventor makes the exterior of the packing case in the form of an ordinary box with a hinged or jointed lid, except that he leaves openings in one or more of the sides of the box in order to permit of the circulation of air through the case for the purpose of keeping its contents cool, or he makes the side or sides in one entire piece, with no openings. He divides the interior of the box or case into a series of square or rectangular divisions or compartments by means of lattice work of galvanized iron wire, the divisions being made of a size proper to fit the bottles to be packed or stored in the case. Near the bottom of the case, that is, the side towards which the necks of the bottles are turned, on the side opposite the door, the inventor fixes a layer of wood or a series of slips of wood, the layer or slips being perforated with holes of a size proper to receive the necks of the bottles, the holes being so made in the wood that they are respectively situated in the lines of the axes of the lattice work compartments.—Patent completed.

446 C. GORDON, Goswell-road. *Breech-loaders.* Dated February 13, 1869.

The breech block is what may be termed a "compound" breech block, and consists of two parts, the forward portion, which may be termed the breech piece, being next the barrel when the breech chamber is closed, and the rear portion, constituting the breech block proper, filling up the remainder of the chamber. The breech piece and breech block are respectively hinged to a transverse pin, and upon the breech block being elevated towards the barrel by means of a lateral projection at the hinder end thereof, may be caused to traverse backwards and forwards in the breech chamber. A loose striker is placed in the centre of the breech piece, the same being of such a length that upon the cartridge being inserted and the breech piece pushed up to the end of the barrel (which is recessed for the admission of the cartridge head, as well understood) the rear end of the striker will project beyond the back face of the breech piece into the end of the breech block, which is open.—Patent abandoned.

447 A. W. TAYLOR, Holloway. *Ceiling walking.* Dated February 13, 1869.

This consists in strongly attaching to the foot of the performer a plate of iron. The face, under side, or surface of the ceiling should consist of a large sheet of brass or other material, and at the top or reverse side of the sheet there should be connections for causing a contact with a very powerful electro-magnet, which, by strongly attaching the iron plates attached to the foot of the performer, keeps him very firmly in a perpendicular position, and as the connecting points of the electro-magnet are moved so the operator is enabled to walk in both a graceful and very surprising manner without fear or possibility of falling. The inventor claims the sole privilege or right of effecting any performance of this kind by the aid or use of electro-magnetism or galvanism in connection with a human being.—Patent abandoned.

448 J. HOLMES, Northampton. *Sash holder.* Dated February 13, 1869.

The inventor adopts a metal frame of a suitable size with an aperture sufficiently large to take the roller hereafter described, made, or provided thereon. The roller works upon a pin, but, instead of this pin working on a fixed centre, a slot or groove in the side bracket is made and the roller is kept in its proper position by means of a spring, one end of which is affixed to the bottom of the inner part of the frame, the other or free end being shaped to fit or nearly to fit the roller and press against it.—Patent completed.

449 W. E. NEWTON, Chancery-lane. (A communication.) *Heating apparatus.* Dated February 13, 1869.

This consists in the employment of lamps of any convenient and suitable construction, which are placed in a vessel (containing water if desired) of a conical or other suitable form, and provided with vertical tubes or pipes through the centre. To the lower end of these pipes or tubes paraffin or other oil lamps or burners are adapted so as to fit closely, in order to prevent the escape of any of the heat. The heat thus obtained from the combustion of the oil rises into a chamber, into which is fitted loosely, so as to allow a space all round, the vessel or receptacle containing the food or water to be cooked or boiled. Suitable openings are left to allow of the escape of the gaseous products of combustion.—Patent abandoned.

450 D. HANTON, Lunan, N.B. *Ploughs.* Dated February 13, 1869.

This consists in uniting together the beams, frames, or bars to which the plough bodies are fastened by parallel links, so that as in a parallel motion when the beams are moved in directions parallel to each other they approach to or recede from each other; therefore, by so moving the beams, frames, or bars the distance between the furrows is regulated.—Patent abandoned.

451 E. G. BREWER, Chancery-lane. *Metallic joints.* (A communication.) Dated February 13, 1869.

This consists in uniting the edges or other parts of tin or other sheet metal plates, so as to produce a perfect water, oil, or air tight joint or seam by means of heat and

pressure effected by suitable machinery capable of uniformly pressing each part of the same into a solid mass without the application of the soldering iron or any additional solder or amalgam beyond that which is contained upon the metallic plates themselves.—Patent completed.

452 S. W. CAMPAIN, Spalding. *Drills.* Dated February 13, 1869.

The inventor substitutes for the cups on the discs flat surfaces placed at such an angle as to lift the material upon them, and also to admit of being scraped by a scraper suspended over the axis of the disc. The angle of the lifters is such that the surfaces become horizontal a short time after they rise above the level of the axis of the disc. The material, when it falls off these flat lifters, drops into the delivering funnels, which lead it to the coulters as usual. There is a scraper for each lifting disc, and it is a blade which, over the axis of the discs, opposes itself to the flat lifting surfaces as they come round. It is suspended from the top of the box containing the discs, and a weight is applied to it to cause it to bear with sufficient force against the face of the lifters. The scraper acts on the lifters on the two sides of the disc, and a notch is made in it to allow it to overlap the edge of the disc on either side a sufficient distance to operate efficiently on the lifters, and the edge of the disc acts as a stop to prevent its falling too far.—Patent abandoned.

453 W. BASFORD, Burslem. *Bricks and tiles.* Dated February 13, 1869.

The inventor proposes, in some cases, for the purpose of improving the strength of the clay or marl, and also for giving a tint by mixing it with pulverised slate rock. Besides this, he takes the shale or bass or brasses which are thrown away as waste from the coalpit, and, when necessary, calcines them, and then mixes the cinder or calcined shale in proportions with the clay or marl. He also uses silicate of iron to mix with the clay or marl, and for that purpose he takes the slags of blast and puddling furnaces, and having reduced them to powder mixes them in suitable proportions with the clay or marl. He proposes, also, to mix with it pulverised anthracite or stone coal. When ironstone dust is used to aid in giving a blue colour to bricks and tiles, it often produces blisters. To correct this the inventor proposes to add a compound composed chiefly of silicate alumina as a substitute for this. He grinds up the old broken saggers and pitchers, and having mixed them with the ironstone dust, introduces them in suitable proportions into the clay or marl. —Patent completed.

454 W. HAYCOCK and W. CARTER, Manchester. *Horse shoes.* Dated February 15, 1869.

This consists in a novel application of pieces of iron or steel (commonly called caulks or spikes) to the shoes of horses, such caulks or spikes being firmly secured thereto by means of screw bolts, rivets, or wedges.—Patent completed.

455 B. HUNT, Serle-street, Lincoln's Inn. *Saws.* (A communication.) Dated February 15, 1869.

This consists in a detachable saw tooth fitted to a recess in the blade and retained therein by a spring catch, so that the tooth may be easily removed and replaced and retained in its place without the aid of rivetting appliances, which tend to distort the blade. The second part of the invention consists of a planing attachment for circular and other saws, the attachment being either part of a detachable tooth or being on a separate plate attached to the blade, the object of this part of the invention being to render the usual rough surface of boards cut by saws smooth and even.—Patent completed.

456 A. MORTON, Glasgow. *Ejector condenser.* Dated February 15, 1869.

This relates to previous letters patent dated July 18, 1867 (No. 2106). It consists in causing a portion or the whole current of the injection water, after passing the steam nozzle, or the last of them when there is more than one, to circulate or return before passing into or through the throat of the lateral-action-inducing and discharge-expanding tube, back through a passage or passages, or other equivalent arrangement into a water nozzle behind the steam jet or jets, as the case may be (where the injection water enters) during the interval between each discharge of steam from the respective ends of the steam cylinder, cylinders, or engines, which returned water may either enter the injection water in a solid central jet or in an angular jet, through correspondingly shaped conoidal nozzles, so as to stop or partially stop the entrance of the injection jet for the time being, while the return current is in action, or combine and mingle with it its outward motion through the condenser or apparatus, instead of the water only passing right out through it as described and practised under the former invention. An extra water nozzle or nozzles may be employed in and for producing this return current in connection with the return passage or passages.—Patent completed.

457 W. H. TAYLOR, Baldwinsville, U.S.A. *Harness buckle and loop.* Dated February 15, 1869.

The side of the improved buckle frame which forms the outer face is made separate from the body of the frame, and is hinged thereto at one end, the other end of the frame being provided with a travelling catch whereby the hinged side of the frame is readily secured and released. The hinged side carries on its inner face a shed which serves as the tongue of the buckle to hold the strap in the frame or loop. One or more of these studs may be used as desired; opposite to each stud is a crossbar or plate in which is formed a hole to receive the tongue or stud when the buckle is closed.—Patent abandoned.

458 W. R. LAKE, Chancery-lane. *Looms.* (A communication.) Dated February 15, 1869.

The boxes are supported in suitable guides or ways, and attached to a rod or other device which is connected to one arm of an elbow lever turning in a stud in the frame; the other arm of the lever, receiving motion from a rod which is actuated by the faces of a graduated slide, has a motion corresponding to that of the loom changes, or, in other words, if it is desired to change after one thread is laid, then the slide moves for every throw of a shuttle, and when changing only. After two threads the slide need move only on the alternate throws, the faces of the slide being so arranged that each moves the lever a different degree, and so as to bring the corresponding box into place, that is, the first face brings up the second box, the second face the third box, and so on, the graded slide turning so as to present the face wanted. This change of position is effected by a lever turning it more or less on its axis, as the lever is lifted or moved by another lever resting on the chain, both levers being connected, and the chain or pattern chain being made with different sized rolls or similar devices to give the different degrees of motion necessary. A gauge plate attached to the elbow lever supports the boxes when raised by means of a drop lever resting on its surfaces and against its faces, which correspond to those of the slide; and the dropping or lowering of the boxes may be effected by raising this drop lever.—Patent completed.

459 E. J. HILL and R. DAVIS, Craven-street, W.C. *Signalling apparatus.* Dated February 15, 1869.

The inventors make use of the natural means of weight as the acting agent, and it is worked upon the principle of a balance scale, and consists of the signal glasses which are attached to a movable frame working in an almost semicircular manner on pivots, and rods attached to the glasses are passed through small holes to the outside of the lamp, the same rods being prevented from extending beyond the outer case of the lamp by small movable lids or caps or other similar contrivance, the momentary removal of which lids or caps effected by the hand or finger causes the change of signals.—Patent abandoned.

460 A. H. LEWIS, Liverpool. *Refining copper.* (A communication.) Dated February 15, 1869.

For the extraction of copper from its ores by this process it is necessary that it should be in a state of protoxide or suboxide or some compound of one of these oxides. Sulphuretted ores are therefore pulverised and thoroughly roasted or calcined in contact with air in a suitable furnace, as a reverberatory, muffle, or terrace furnace, from which the sulphurous acid produced may be collected to be made use of in the production of sulphuric acid, or for the treatment of oxychloride of iron as hereinafter described. For the native oxidised ores, such as the black and red oxide, the carbonates and oxychlorides of copper, calcination is not necessary, but they must be finely pulverised.—Patent abandoned.

461 T. HATTERSLEY, Leeds. *Spindles and flyers.* Dated February 15, 1869.

This consists in an improved mode of fixing the flyer upon the spindle by means of a clutch or catch made to fit into a corresponding clutch or catch on the top of the spindle instead of by means of a screw as at present used. The form of this clutch or catch is such that the flyer locks itself upon the top of the spindle by a slight turn either to the right or left hand, so that the same spindle and flyer can be used for right hand as well as left hand twist, and therefore this invention does away with the necessity of having spindles with two threads on the top, one a right hand thread and the other a left hand thread, and two flyers to each spindle with threads to correspond, as is frequently the case in silk spinning.—Patent abandoned.

462 C. W. LANCASTER, New Bond-street. *Cartridges.* Dated February 15, 1869.

In order that cartridges for breech-loaders may throw as closely as wire cartridges in muzzle-loaders or nearly so, the inventor employs, over the shot and under the ordinary terminal wad of the cartridge, a hollow cylindrical wad, formed of a short piece of cylinder of paper or other material closed at the end by the insertion of an ordinary cloth or other wadding. This short cylinder he forms to fit inside the cartridge case, and he inserts it after pulling in the shot so that it forms a cap or thimble over the front portion of the charge of shot. This hollow wadding is then secured in its place by the ordinary terminal wad, over which the cartridge case is turned.—Patent completed.

463 S. SHAW, Boston, U.S.A. *Buttoning boots.* (A communication.) Dated February 16, 1869.

The inventor takes a piece of metal of the proper size and turns a rounded head thereon. Below this head he turns a circumferential groove. He then forms a shank or stem of less diameter than the body of the stud, with a shoulder just below the groove, and this stem he makes tubular or hollow and of sufficient length to reach through the leather, so that when the stud is inserted therein its end may be turned over on the inside and riveted in the same manner as an ordinary metallic eyelet. The flange which is formed by thus turning down the inner end of the tubular shank or stem serves to hold the stud securely in place. Instead of being turned, the studs may be formed in dies or by any other suitable means, and they may be made with one or more circular grooves for the lace or cord, and may be either plain or ornamental, as desired.—Patent abandoned.

464 T. BOND, Liverpool. *Making casks.* Dated February 16, 1869.

This consists essentially in the employment of a reciprocating or vibrating knife of any suitable shape, caused to move in slides or guides by a crank, eccentric, or other means. The stave blank or stave to be shaped is placed on a table of the required shape and adjustable, if necessary, and at each double stroke the knife cuts off the superfluous timber from the whole or a portion of one side. Second, in an improvement in the machine for finishing the ends or heads of casks known as the "head lathe."—Patent abandoned.

465 T. WINDER, Liverpool. *Spring coupling.* Dated February 16, 1869.

The inventor constructs a hollow cylinder of metal or other strong material and fits thereto a piston, or its equivalent piston rod. The piston rod passes through a firmly secured cylinder cover. Surrounding the piston rod and between the cylinder cover and piston, or its equivalent, he fits a cylinder of india-rubber or other elastic gum, hereafter called rubber; or rings or cones of the same material, separated by rigid plates if considered desirable, can be employed. At or near the end of the cylinder, and also at or near the end of the piston rod, eyes or other connecting agents are formed to allow the coupling to be connected into or to links or other parts. Any sudden strain or jerk given to the coupling will, as regards its damaging effects, be neutralised in consequence of the yielding of the rubber. When fitted in tiller chains, in steering apparatus, and for other purposes on board ship, and in other places where slackness of the chains or other parts is objectionable, the inventor combines with the above described cylinder, piston, and rubber tightening screws of any ordinary or convenient construction.—Patent completed.

466 H. POSEN, Offenbach. *New fastening.* (A communication.) Dated February 16, 1869.

One portion or member of the fastening consists of a fixed plate, block, or piece, in which is a recess or notch, and on or over this plate is another but movable plate, which is free to work by sliding action or otherwise in such manner as to cover and uncover the recess or notch, according to the direction in which the plate is worked. The other member or portion of the fastening consists of a stud, tongue, knob, or projection, called the "projection." It is of such form as to correspond with and fit in the recess, and is so arranged and situated as to be capable of being placed in and taken out of the recess with facility when required.—Patent abandoned.

467 T. BILLYEALD, Nottingham. *Ladies' nets.* Dated February 16, 1869.

The object of this invention is to give greater finish and neatness to the appearance of nets for ladies' hair. The inventor forms the fabric in breadths corresponding with the width of the desired nets, the respective breadths being united during manufacture by lacing or connecting threads. Transverse lines may also be applied to define the size in that direction.—Patent completed.

468 W. SMARTT, Buckhurst-hill. *Utilising waste heat.* Dated February 16, 1869.

The inventor uses the heat under sitting-room, office, and other similar fires, for heating, cooking, warming, and drying purposes, and with this object he adopts a portable apparatus or oven, which is specially constructed and adapted for being suspended, supported, or placed for use under fires. Things or articles intended to be heated, cooked, or warmed, or dried, are according to the circumstance in each case, either placed in vessels in the ovens or simply in the ovens. The ovens with contents are then moved into the spaces under the fires when the said spaces do not contain too large a quantity of ashes; or the ovens may be under the fires before recovering the said things or articles.—Patent completed.

469 L. N. LEGRAS, Wardour-street. *Preserving animal substances.* Dated February 16, 1869.

This apparatus consists of three chambers or reservoirs of iron or other suitable metal or material and of any convenient form placed one inside another. The outer chamber may be made of wood, and is supported upon feet to raise it from the ground. It is to be filled with any good non-conductor of heat, such as felt, powdered charcoal, or carbonised sawdust. The next inner compartment is to be filled or partially filled with ice or other refrigerating substance or substances, whilst the third compartment or chamber serves to contain the meat or other substance to be preserved, such, for example, as butchers' meat, game, poultry, or fish, or, if desired, the third compartment may be employed for the preservation of raw hides, thereby keeping them perfectly sweet and fresh.—Patent completed.

470 Abstract will appear in a future number.

471 G. W. R. PIGOTT, Halifax. *Tension and compression apparatus.* Dated February 16, 1869.

The form of material, whether metallic or not, preferred to be operated upon by this apparatus is a continuous one, such as a band, plate, ribbon, rod, tube, or wire capable of being drawn or thrust through drawing plates or rollers to give any required sectional form. The apparatus consists of certain vices, nippers, or holders, capable of travelling to and fro or remaining at rest, and certain compressing tools in frames capable of sliding or rocking backwards and forwards either in the direction of the line of travel of the vice or holder, or laterally thereto, such vices, holders, or compressing frames, or some of them, being furnished with suitable tools for shaping, moving, or holding the material to be consecutively operated upon, such as dies, punches, cutters, drills, or polishers actuated by suitable mechanical power applied by the usual means of communicating motion, such as levers, cams, cranks, or eccentrics.—Patent completed.

472 B. J. B. MILLS, Southampton-buildings. *Brick making.* (A communication.) Dated February 16, 1869.

This consists, first, in an arrangement of paired mould wheels, the peripheries of which contain a series of equidistant radial compartments or moulds, with intervening spaces on each periphery, the wheels being so geared together that the moulds of one revolve in close juxta-position with the periphery of the other. The moulds of each wheel contain plungers operated by a fixed cam attached to the frame of the machine and operating inside of the wheel with a loose journal at its centre, around which each respective wheel with its series of plungers revolves. Second, in an arrangement of devices whereby the moulds are completely and continuously charged with the clay in proper quality and quantity. Third, in providing apparatus, such as tongue scrapers and rollers, for ensuring a smooth and dense finish to the bottom of the brick.—Patent completed.

473 C. E. BROOMAN, Fleet-street, E.C. *Treating animal waste.* (A communication.) Dated February 16, 1869.

This consists in treating the waste of wool, silk, horn, hides, feathers, and other animal substances with a mixture of sulphuric and nitric acids, whereby products are furnished which will act upon phosphates and coprolithes, and form nitrated super-phosphates of great value for manure.—Patent abandoned.

474 H. TYLOR, Queen-street, E.C. *Spring bedsteads.* Dated February 16, 1869.

The object of this invention is to construct spring bedsteads, as distinguished from spring mattresses, by fixing a number of springs between two sets of laths or bars, as hereafter described. The side rails or angles of the bedstead are pierced with a series of holes; into these holes pins are dropped, the pins depend from the ends of stout bars which stretch across from one side rail or angle to the other. These bars have eyes or their equivalents fixed on them to hold the lower coils of the springs, and the upper coils of the springs are connected in a similar manner to the under side of the upper set of laths or bars. These upper laths are attached to studs fitted on an additional side bar or rail fixed parallel to and above the side rails or angles first mentioned. There may be a number of straps on the under side of the upper cross laths through which the long laths may be passed, their ends being secured to other cross bars fixed parallel to and above the head and foot angles or rails.—Patent completed.

475 A. M'NEILE and J. SLATER, Pentonville. *Carriage wheels.* Dated February 16, 1869.

This relates, first, to certain improved modes of constructing the felloes of wheels and securing the ends of the spokes thereto. Second, to improvements in the construction of the naves and axle boxes of wheels, and relates more particularly to cast or wrought-iron axle boxes or naves.—Patent abandoned.

476 J. FLETCHER, Bow. *Begass furnaces.* (A communication.) Dated February 11, 1869.

This consists, first, in applying an arrangement of mechanism, or apparatus, to the begass furnace, whereby it is fed in a more continuous, regular, and economical manner than by manual labour. This mechanism or apparatus consists of a hollow trunk or chamber of a square or rectangular form inside (having its four inner sides planed) fixed in a horizontal position in front of the begass furnace, and having one end connected thereto and communicating with it. The upper side of the trunk is fitted with a hopper to receive the begass having a hole in its bottom communicating with the inside of the trunk through a corresponding hole in the top of the trunk.—Patent completed.

477 F. WALTON, Staines. *Artificial leather.* Dated February 16, 1869.

In making artificial leather, the inventor cements together two or more thicknesses of calico or other fabric by means of oxidized oil cement, as described in a patent granted the 4th August, 1869 (No. 1801), and having so obtained the required thicknesses, he japans the surface as is now practised in the manufacture of what is generally known as patent leather.—Patent completed.

478 H. MULLINER, Leamington Priors. *Hanging broughams.* Dated February 16, 1869.

The inventor constructs a perch of steel, iron, or other suitable material with which he connects the ordinary beds and springs of an under spring carriage, and suspends the body upon the under carriage so constructed by means of frame work of iron, steel, or other material on the bed or beds carrying a cross spring with which he connects the body by means of elbow springs, or he employs a cross spring of elliptic shape and connects the body with the same by means of ironwork.—Patent abandoned.

479 J. W. YATES, Birmingham. *Spades, shovels, &c.* Dated February 16, 1869.

This relates to those parts of spades, shovels, forks, and other similar articles called the straps or langets, by which the tree or cylindrical part of the handle is connected with the blade, plate, or fork of the articles. The straps or langets, as ordinarily constructed, consist of pieces of iron or steel situated in planes parallel or nearly parallel to the blade, plate, or fork. When the tree or cylindrical part of the handle is placed and fastened between these straps or langets one of the straps or langets is situated at the front and the other strap or langet at the back of the tree or cylindrical part of the handle. By this arrangement of the straps or langets they are liable to break at their junction with the blade, plate, or fork in consequence of the great strain which takes place at those parts, and the object of this invention is to remedy this defect.—Patent completed.

APPLICATIONS FOR LETTERS PATENT.

Dated August 31, 1869.

2572 F. W. Potter, Barbican, City. A new or improved construction of wirework, applicable for sieves, screens, and various other articles in which wirework is used.

2573 F. Durand and C. Beslay, Paris. Applying the incompressibility of liquids for imparting the required stiffness to suitable supple bodies for allowing them to be made use of as armatures for building tunnels or other submarine constructions, or for divers other useful purposes.

2574 A. P. Tronchon, Rue Ste. Appoline, Paris. Improvements in the construction of elastic seats.

2575 A. M'Netie, John-street, Pentonville, Middlesex. Improvements in brakes for retarding the progress of wheeled carriages.

2576 W. Glover, Prestwich, Lancashire. Improvements in looms for weaving.

2577 W. E. Newton, Chancery-lane. Improvements in washing machines.

2578 T. Coles, Fort-place, Sandy Hill, Woolwich, Kent. Improvements in the construction of the running wheels of carriages and other vehicles mounted on wheels, and wheels and riggers used in machinery.

2579 T. Wardlaw, Toughmill, Dunfermline, North Britain. Improvements in reaping machines.

Dated September 1, 1869.

2580 T. Wilson, Birmingham. Improvements in screw and ratchet wrenches, part of which improvements is also applicable to pipe cutters.

2581 J. Grice and J. G. Harrison, Birmingham. Improvements in axles for carriages.

2582 J. Shand, Upper Ground-street, Blackfriars, Surrey. Improvements in direct-acting steam pumping engines and steam fire engines.

2583 S. Schiff, Great Alie-street, Goodman's-fields, Middlesex. Certain improvements in the mode of filling or charging pipes for smoking tobacco, and the apparatus or box for containing such pipe, priming, or charges, and lights in combination therewith, called the Premier pipe cigar.

2584 W. S. Laycock, Portobello-place, Sheffield. Improvements in weaving certain kinds of fabrics.

2585 G. H. Nussey and W. B. Leachman, Leeds. Improvements in machinery or apparatus for pressing woollen and other woven or felted fabrics.

2586 T. Greenwood and J. Bapty, Leeds. Improved machinery for combing silk and other fibrous materials.

2587 B. Isangk, Ile Lacroix, Rouen, France. Improvements in apparatus for indicating and registering the pressure of steam or other gases or liquids, called Manograph or self-registering steam gauge.

2588 R. Scott and W. M'Ivor, Addiewell, North Britain. Improvements in the treatment of hydrocarbon oils.

2589 A. M. Davis, Bexley Villas, Bromley, Kent. Improved aerated alcoholic drinks.

Dated September 2, 1869.

2590 S. Willis, Swannington, Leicestershire. Improvements in railway chairs.

2591 R. Pitcairn, Trafalgar-square, Middlesex. A new or improved rest for supporting the arms, feet, or body of a person, or books and other small objects.

2592 J. Day, Manchester. Improvements in the means of raising or closing the glasses or shutters of carriage doors and windows.

2593 P. M'Gough, Halifax. Improvements in sash frames and sashes, particularly applicable to the windows of railway and other carriages.

2594 F. Prestage, Gresham-street, City. An improved arrangement of apparatus to be adapted to railroad carriages for the purpose of assisting in retarding their progress when desired, and also for assisting in starting a train after a stoppage.

Dated September 3, 1869.

2595 E. D. Temple, Circus-place, Finsbury-circus, City. Improvements in the construction of telegraph railway signal, scaffold, and other posts.

2596 S. H. Greaves, Sheffield. Improvements in the manufacture of knives and forks, spear points, daggers, and such like instruments, and in the means or apparatus employed therein.

2597 T. Slater, Euston-road, St. Pancras, Middlesex. Improvements in the construction of electro-magnetic machines as motors, and in the construction and mode of exciting batteries, and in the application of such motors and batteries to various useful purposes.

2598 A. M. Clark, Chancery-lane. Improvements in steam boilers.

2599 H. Bridgewater, Watford, Herts. Improvements in railway chairs, and in the means of securing bridge and flanged rails to their sleepers.

2600 R. Spear, New Haven, Connecticut, U.S.A. Transmitting power for operating marine signals, and for other purposes, by means of air or fluid.

2601 A. Ogg, Kynaston-street, Lambeth, Surrey. Improvements in printing machines.

2602 W. H. Burnett, Great Coram-street, Brunswick-square, Middlesex. Improved modes of signalling on railways by means of sound, and apparatus to effect the same.

2603 G. Henley, Essex-street, Islington, Middlesex. Improvements in dial or needle and alphabetical telegraphs and relays.

Dated September 4, 1869.

2604 J. G. Lynde, Manchester. A diaphragm indicator especially adapted for water and other meters.

2605 J. Webster, Birmingham. A new or improved nozzle for blowing air, steam, water, or other liquids and gases, and blowing, drawing, mixing, and forcing fluids and vapours.

2606 H. Defries, Houndsditch, City. A novel application of glass to decorative or ornamental purposes.

2607 J. Juckes, Wigan, Lancashire, and E. Wood, Bolton, Lancashire. Improvements in the construction of furnaces.

2608 P. Spence, Newton Heath, Manchester. Improvements in the separation of copper from ores.

2609 W. Ambler and B. Jowett, Bradford, Yorkshire. A new or improved method of advertising, and the application of automatic means or apparatus to be employed for that purpose.

2610 J. Hargreaves, Fylde-road, Preston, Lancashire. Improvements in extracting phosphoric acid and phosphorus from the tap cinder of puddling furnaces and iron refineries, and from other compounds of iron and phosphorus.

2611 W. H. Reade, Great Sutton-street, Clerkenwell, Middlesex. Improvements in machinery for clipping and cleansing the hair of animals.

2612 J. Porteous, Edinburgh, and H. Gibson, Musselburgh, Midlothian. Improvements in the manufacture of tobacco, and in the machinery or apparatus employed therefor.

2613 W. Wright, Mostyn, Flintshire. Improvements in the treatment of burnt cupreous pyrites for the extraction of the metals contained therein.

2614 F. H. W. Heuer, South-place, Finsbury, Middlesex. Improvements in velocipedes.

2615 W. S. Clark, Street, Somersetshire. Improvements in the manufacture of boots and shoes, and in machinery and apparatus employed therein.

Dated September 6, 1869.

2616 C. F. Claus, Middleborough-on-Tees. Improvements in the manufacture of carbonate of soda, and in the recovery of waste products resulting therefrom, and in the construction of apparatus to be employed for such purposes.

2617 T. S. Webb, Norton Ironworks, near Stockton-on-Tees. Improvements in the manufacture of iron and steel.

2618 J. Edwards, Richmond-road, Hackney, Middlesex. Improvements in railway carriages, and in means for communicating from one to another of the same.

2619 C. D. Escoffier, Finsbury-circus, Middlesex. Improvements in the construction of castors or rollers for furniture, and applicable where castors or rollers are or may be employed.

2620 E. T. Hughes, Chancery-lane. Improvements in the construction of doors and similar articles.

2621 T. H. Blamires, Huddersfield. Improvements in rubbers for condensing and piecing machines.

2622 W. E. Newton, Chancery-lane. Improvements in reaping and mowing machines.

2623 F. Wicke, Bockenheim, Prussia, J. Bronner, T. Petersen, and J. G. Zehfuss, Frankfort-on-the-Maine, Prussia. Certain improvements in the treatment of human excrements, whereby they are converted into an inodorous, dry, and easily portable manure.

2624 W. E. Gedge, Wellington-street, Strand. Improvements in apparatus for rectifying alcohols.

2625 S. F. and A. B. Ibbotson, Sheffield. Improvements in joints for uniting and securing the ends of railway rails.

2626 W. R. Lake, Southampton-buildings, Chancery-lane. Improvements in velocipedes.

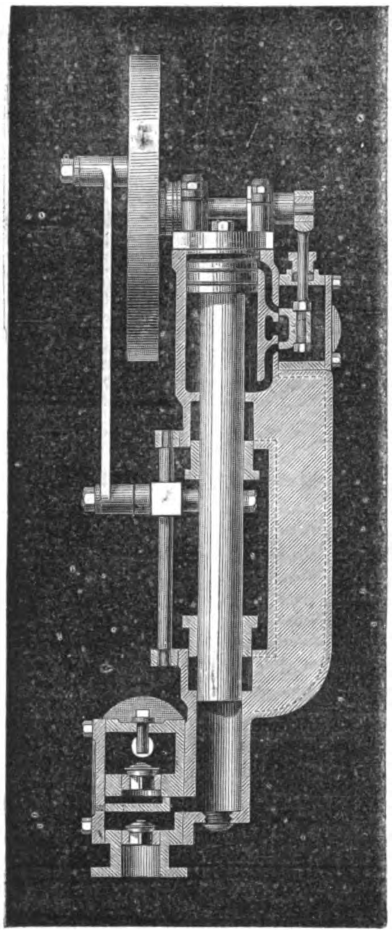
NOTICE.—Having received communications from persons residing in the country to the effect that difficulties are occasionally experienced by them in obtaining copies of printed specification from the Patent Office, in consequence of the varying nature of the postage thereon, our readers are informed that upon receipt from them of particulars of the specifications they require, together with a remittance for the cost and approximate postage thereof, we shall be happy to procure and forward such specifications free of all further charge. Sums under Five Shillings may be remitted in postage stamps, for sums above that amount a Post Office Money Order should be sent, payable to ROBERTSON, BROOMAN, and Co., Patent Department, 166, Fleet-street, London, E.C., to whom all communications upon the subject should be addressed.



ALEXR. WILSON & CO.,

ENGINEERS,

VAUXHALL IRON WORKS,

NINE ELMS, LONDON, S.W.,

MANUFACTURERS OF

IMPROVED DONKEY PUMPS, INJECTORS, SAFETY VALVES, STOP VALVES, AND BOILER MOUNTINGS OF EVERY DESCRIPTION.

PRIZE MEDAL, HAVRE MARITIME EXHIBITION.

The attention of Engineers is particularly called to the "Vauxhall" Improved Donkey Pumps and Injectors, which are now used by all engineers. They are the best Boiler Feeders ever brought before the users of steam power, and for boilers supplying steam to apparatus, other than the steam engine, they are indispensable, while they are rapidly supplanting the feed pump on the engine itself, as they dispense with the necessity of running a large engine merely to get a little water into the boiler. They are at work on board ships and steamers, in breweries, distilleries, gas works, tanneries, chemical works, and in every situation where single, double, and three-throw pumps have hitherto been used.

N.B—They are proportioned to draw 15ft. and force into the boiler supplying steam to them; when they draw more than 15ft. the rams have to be made smaller. In pumping water they will throw it 2ft. high for every pound pressure of steam in the boiler.

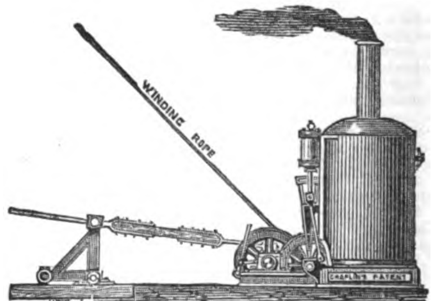
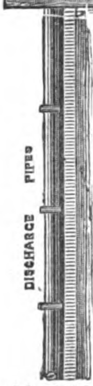
CHAPLIN'S

PATENT PORTABLE

STEAM ENGINES,

FOR PUMPING AND WINDING.





SPECIALLY ADAPTED FOR PITS, QUARRIES, &c.; SIMPLE AND STRONG; REQUIRE NO FOUNDATION OR CHIMNEY STALK, AND ARE EASILY ERECTED OR REMOVED.

Sizes, from 2 to 30-horse power.

Stationary Engines, 1 to 30-horse power, with or without gearing.
Steam Cranes, 30 cwt. to 20 tons, for Wharf or Rail.
Hoisting Engines, 2 to 30-horse power, with or without jib.
Contractors' Locomotives, 6 to 27-horse power.
Traction Engines, 6 to 27-horse power.
Ships' Engines, for Winding, Cooking, and Distilling, passed by H.M. Government for half-water.
Steam Winches. Engines and Boilers for Light Screw and Paddle Steamers.

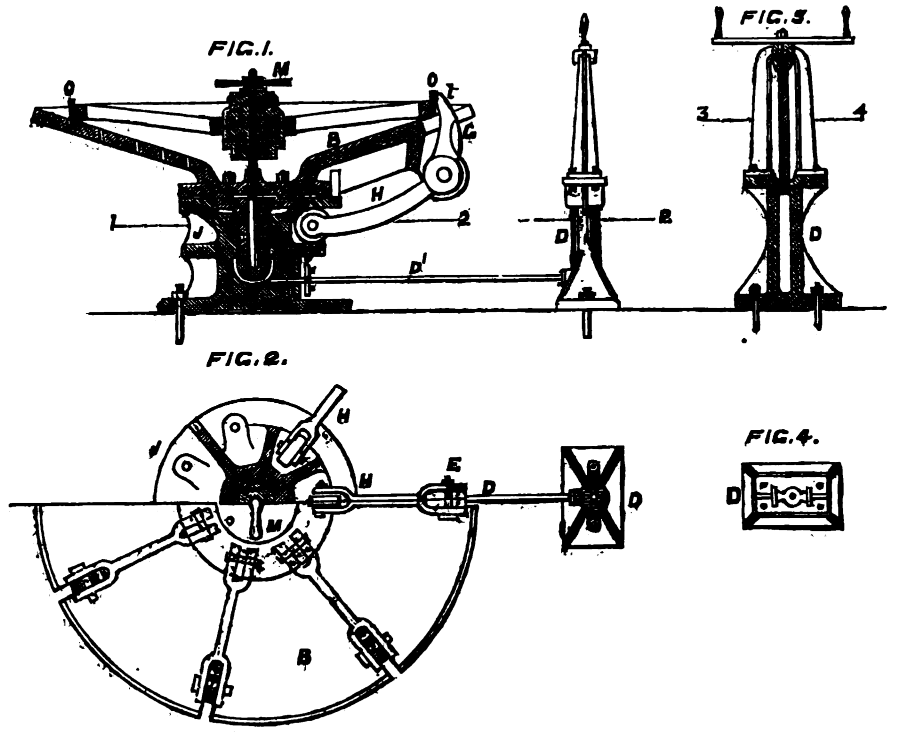
LONDON: FRIDAY, SEPTEMBER 17, 1869.

MACHINE FOR COMPRESSING WHEELS.

OUR readers are familiar with the ordinary method of attaching a tyre to a wheel, in which the object is effected by heating the metallic rim and permitting it to compress the wheel after cooling. Recently a patent has been taken out by M. A. Colas which reverses these conditions, and also materially facilitates the putting together of the various parts of the wheel. The two principal advantages claimed by the inventor are, that by attaching the tyre when cold, all chance of burning the felloes is obviated, which frequently takes place with the hot tyres, and that there is no danger of injuring the elasticity and homogeneity of the metal by a violent and sudden alteration of temperature. According to the new principle, the metallic tyre is made and applied in its normal dimensions and conditions, but the wheel itself is maintained in a state of strong compression throughout the whole of its circumference while the operation of fixing the tyre is accomplished. So soon as this is completed, the artificial force of compression is removed, and the wheel recovers the elasticity of which it had been temporarily deprived. It is evident that the whole operation designed by M. Colas is exactly the inverse of that in ordinary practice among wheelwrights and manufacturers. In addition to the difference in the two systems the means of carrying into practical execution the one under consideration are sufficiently novel and ingenious to deserve a detailed description.

The present apparatus employed by the inventor, which has had many improvements added to it suggested by experience and the deficiencies of its predecessors, is illustrated in the accompanying cuts. A vertical section is represented in fig. 1, a plan with two views in fig. 2, and the two remaining figs. show a vertical and horizontal section of the pump which injects water into the machine. The wheel A is placed upon the frame B, which has its external surface of a conical shape and is capable of being raised by the piston C, attached to the hydraulic pump D. The tube D' conducts the water under the piston. When the frame B is raised, it carries with it the axes E. Upon these latter are placed the compressing levers G and the connecting rods H, which turn freely upon the pivots I attached to the frame J. It results from the upward motion of the platform B that the levers G bear against the small arms *t*, and press them against the felloe of the wheel A. In consequence of this compression, the diameter of the wheel is reduced, and it descends, or settles down a little lower in the conically shaped frame B, under the action of the hand screw M, which passes through the centre of the frame. The manner in which the introduction of the tyre is accomplished now remains to be described. In its present stage the wheel is compressed by the arms *t*, and also held firmly in its place by the screw M and the conical shape of the platform B, so that the pressure of the levers G may be relaxed, and the tyre inserted in its place. Directly this is effected the operation is finished. The pressure of the screw M is removed, and the wheel, restored to its normal condition of elasticity, presses against the tyre with sufficient force to become firmly fixed to it without the aid of heat, but by a simple and rapid mechanical operation. Within certain limits there would not appear to be any difficulty in adapting the machine to wheels of different diameters, as the levers of compression G have a certain amount of play, and the conical form of the platform B could receive circumferences of different size. Obviously it would never do for a manufacturer to purchase a machine for every sized wheel that he might be called upon to supply. As a rule, there are certain sizes usually recognised for the different descriptions of vehicles, so that it must not be imagined that their manufacture is altogether a matter of chance. The simplicity of the method proposed by M. Colas needs no comment. So far as the motive power is concerned, any other suitable means might be employed instead of hydraulic agency wherever the latter was not available.

MACHINERY FOR COMPRESSING WHEELS.



CONCRETE STONE IN INDIA.

ALL who are acquainted with Bombay are well aware how badly it is off for good building stone. The materials in ordinary use are trap and Porebunder stone, the former of which gives a heavy ponderous appearance to the buildings, whilst the latter is of a very perishable nature. The Coorla stone is much more durable, but it is so hard as to be almost unworkable. The stone from Hemnuggur answers well, but the cost of transit is so great as to preclude its use in all but very special cases. Hence the want of a good and cheap building material has been long and seriously felt in Bombay. That want, we are glad to find, is now supplied by the introduction of Mr. Ransome's siliceous stone. The value of this invention having become known to the Secretary of State, the manufacture of the Ransome stone was forthwith directed to be carried out at the Government works in Bombay. An establishment was organized by Mr. A. Pye-Smith, a gentleman from the inventor's works at East Greenwich, and is now in full work, producing stone on Mr. Ransome's beautiful principle. The new stone appears to afford much satisfaction, and the prospect of a material at once pleasant in colour, enduring in texture and moderate in price, is especially cheering where such serious drawbacks as those to which we have referred exist. The introduction of the stone, too, is singularly opportune, inasmuch as the Government is just commencing a series of large buildings, which it was wished to make as permanent as possible. The Ransome stone—as our readers are for the most part aware—is produced by dissolving flints in caustic soda and mixing the resulting silicate of soda with dry siliceous sand and limestone powder. The paste thus formed is moulded to any desired shape, and then hardened by immersion in a solution of chloride of calcium. A shower bath of cold water drives off the chloride of sodium, and the stone, after being dried, is ready for use.

Our readers will doubtless remember, from our description of the Ransome's Stone Works at East Greenwich, that the process of saturation with the solution of chloride of calcium is accomplished by hose playing on the blocks, as well as by immersion. Mr. Ransome has, however, improved this part of the process, and in connection with his son, Mr. Ernest Ransome, and the well-known Mr. Bessemer, has recently obtained another patent, in which is claimed the "saturating, washing, and drying blocks or moulded pieces of artificial stone by means of a vacuum or pressure, or by both vacuum and pressure combined." And the works have now been fitted up with air pumps and other apparatus for this purpose with the most satisfactory result. In the Government Works at Bombay Mr. Pye-Smith has introduced another very ingenious arrangement for carrying out this part of this process, consisting of an airtight iron chest, into the upper side of which a pipe is carried from a tank placed at a considerable height above the building. The chest has a movable bottom, which is lowered by a winch and placed on a traveller. When the plate has been loaded with moulded material—the pieces being placed over vents made in the movable bottom—it is placed beneath the saturator, which somewhat resembles a diving bell. It is then screwed up in its place and well packed, the cock of the down pipe is then opened, and the chloride of calcium admitted under the pressure of a good head. It rapidly permeates the soft masses exposed to its action and converts them into durable stone, after which they are treated with water in the usual way. The only drawback the manufacture at first experienced was the difficulty of obtaining sand of the proper quality. There is no siliceous sand in or near

Bombay, but, after several journeys, Mr. Smith found a supply at Kutch Mandive. The limestone powder is readily obtained by pounding Porebunder stone to a sufficient degree of fineness. The natural materials being thus formed the manufactured ingredients, such as the silicate of soda and chloride of calcium, are readily obtainable, and thus enable this important manufacture to be developed where it will prove of the greatest value. It supplies a want created by the absence of natural stone of the proper quality for building purposes, and bears striking testimony to the special merit of Mr. Ransome's invention.

MANUFACTURE OF CAPS AND CARTRIDGES.

No. X.

It has been already stated that the brass ends or sockets into which the cartridge case fits are manufactured and annealed at the premises in the "Rue Notre Dame des Victoires," and in this condition are forwarded to the branch of the establishment situated at Moulineaux. As a preliminary preparation for the future modifications they are destined to undergo they are cleaned and polished by the united action of an acid, sawdust, and the revolving barrel, from the last of which they emerge "bright." The other component parts, namely the case, the "piece" with the chamber, and the "renfort," have been brought to a similar advanced stage, and they are all despatched together to the workshop, where the operation of uniting them is effected. This is accomplished altogether by women, and is one of the most interesting and curious of the many processes connected with the manufacture. Hand labour is ingeniously aided and supplementalised by the employment of mechanical agency. The workwoman stands in front of an iron table, which supports upon her left a small frame carrying a mandrel moving horizontally from front to back. Opposite to it is placed an anvil separated from the extremity of its stroke by a distance about equal to the length of a cartridge. In the centre of the table is an opening or slit, in which is fixed a copper wheel revolving in a small reservoir containing paste, while in an oblique direction to the same aperture is situated a bracket furnished with a groove which serves as a guide for the introduction of the cartridge. On the right of the workwoman the various component parts of the cartridge are arranged, and she holds ready in her hand a short mandrel, a trifle longer than the cartridge itself. Taking the case in her right hand, she inserts the "piece," passes the mandrel inside the case, and presses the end of it against the anvil on her left, and upon which descends the punch having a conical section. The slight pressure bestowed upon the end of the case depresses it a little and enables it better to receive the brass end piece. Previous, however, to the case undergoing this pressure, it is brought for a moment into contact with the small copper wheel already alluded to, which gives it a thin coating of paste, and causes the brass end to adhere firmly to it. The operation is terminated by presenting the end of the cartridge to the flat part of the anvil and permitting the punch to descend upon the mandrel inside the case. The pressure drives the "piece" well down and fixes it in its place. So quickly is the whole process performed that without close attention, the unpractised eye can scarcely follow the various motions. Some of the best hands can turn out as many as six thousand of these cases in one day's work.

Similarly to their warlike brethren, the sporting cartridges have to be "struck," but a rather gentler and more delicate kind of machine is employed in their case. The motion moreover is vertical instead of horizontal, and the apparatus strongly resembles a rivet-head making machine, as will be at once perceived by the description. In front of the workwoman is placed a disc carrying at the circumference twenty hollow sockets, into which the cartridge cases are inserted with the brass ends uppermost. Exactly as in the rivet machine, the rotation of the disc brings each case in turn under a punch, which drives the brass end up to its proper place, and also compresses the "piece" into half its original thickness. At the same time the chamber is enlarged, and one of its sides bevelled off so that the priming may be easily introduced, and the passage prepared for the needle. By the same stroke the number indicating the gauge of the cartridge is stamped upon the metallic end, together with the trade mark of the establishment, and the rim, serving to retain the case in the gun, also formed. The next step is to prime the cases, which is a twofold operation, the first part consisting in the boring of the hole through which the needle passes, and the second in the introduction and fixing of the needle and priming. A drill worked by a lathe at a very high velocity effects the piercing of the necessary aperture. The priming is placed in a little kind of stirrup and introduced into the cartridge, while a horizontal rod holds the needle, which is inserted to the proper depth by means of a small lever. There are some objections to this description of priming. According to the degree of acuteness of the drill, the diameter of the hole is subject to variation, which is a very undesirable result. At the moment of firing, the metallic end undergoes a considerable dilatation, due to the pressure produced by the gas, and the aperture for the needle permits of the passage of gas in a high state of inflammability, carrying with it particles of metal and paper. Moreover, the aperture itself being enlarged, the needle is liable to be blown out by the pressure. In fig. 1 is shown a longitudinal section of a

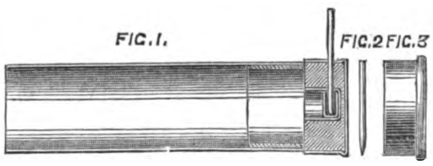


FIG. I. FIG. 2 FIG. 3

cartridge after being primed and the needle inserted. Figs. 2 and 3 show respectively the needle and the metallic end piece.

To remedy the serious defect in the method of priming already described, M. Gevelot has substituted for the action of the drill that of a steel punch. This latter acts like a nail when driven into a piece of wood, and penetrates through the breech of the cartridge, at the same time that it compresses together all the material in the neighbourhood of the aperture, which is thus rendered exactly equal in diameter to that of the needle intended to fill it. At the moment of expansion of the gases by the firing of the arm, their action forces the ring of compressed metal and paper resulting from the pressure of the steel punch closely all round the needle in a manner similar to that in which the leather collar acts in a hydraulic press, and effectually prevents all escape of gas. A very simple machine suffices to perform this operation. The priming is introduced into the cartridge as in the former method, and a frame is employed, working backwards and forwards between two guides, and carrying a wheel furnished with two piercers of unequal length and the needle. Three blows are imparted by means of a lever. At the first, a slight depression is made in the metal and the upper layers of the paper in immediate proximity to it; at the second, the other piercer follows in the path of its predecessor, but penetrates deeper, as far as the chamber. The third blow brings the needle itself in front of the aperture into which it is inserted, driving before it in its passage the loosened and broken particles of paper and metal. This system of priming, by its great simplicity and facility of execution, has considerably increased the manufacture of cartridges for breechloaders. The cartridges have yet to be filled and charged, and they are then ready for exportation.

PHOTOGRAPHY.

THE PHOTOGRAPHING OF MACHINERY—REMOVAL OF NITRATE OF SILVER STAINS—THE PHOTOGRAPHING OF SPIRITS—A NEW POLARISING PRISM—ALKALINE WET PLATES.

A NOTICE has appeared in the "Scientific American" to the effect that M. Bourbouze has succeeded in representing by photography machinery in motion. The statement is that he constructs his photographs in movable parts as transparencies upon glass; each movable organ is photographed on a separate glass, and the fixed parts upon another glass plate. The fixed parts and the movable glasses are arranged in a frame, and motion is given to the latter glasses by means of a winch so as to represent the actual motion of the machinery. The whole is then in all probability illuminated by the lime light and projected on a screen, but the published notice is so brief as to give too little information. A plan by which moving figures have been successfully represented is to take several small transparencies of the moving object in its different positions, and to arrange these pictures in a circle near the rim of a large flat wooden disc. This disc is made to spin round in front of a magic lantern, so that all the pictures are brought in succession into the focus of the object glass, and thereby thrown upon the screen one after the other. By the law of the retention of vision, the object then appears to be in motion, supposing the wheel to be driven at the proper speed, and each picture to be rendered stationary for the instant that, by suitable appliances, it is flashed upon the screen.

In order to remove the dark stains of nitrate of silver from linen without destroying the fabric, Herr Grimm recommends that the stain be first treated with chloride of copper, to produce chloride ot silver by double decomposition, and that then the spot be treated with hyposulphite of soda. When the silver has been thereby dissolved, the linen should be well washed. Another plan is to treat the stain with a weak solution of permanganate of potash to which some hydrochloric acid has been added, and then to finish with hyposulphite of soda and washing, as before. A solution of iodine in iodide of potassium also answers the purpose for the first washing.

A very great deal has been published in all the photographic journals for many weeks past about the Mumler spirit photographs. It will be remembered from the notices which appeared in the newspapers, that a photographer named Mumler has been for many years taking photographs in New York wherein shadowy human forms accompany the sitters, which forms have usually been alleged by the sitters to represent deceased relatives of their own. Nothing is easier than to produce good ghost pictures with the connivance of the sitter, but nothing of this kind took place in producing the Mumler photographs. Mumler was prosecuted as an impostor by the photographers of New York, but many respectable witnesses came forward and swore that the pictures produced in their presence were actually those of their deceased relatives, and one of these witnesses was Mr. Livermore, the New York banker. The result of the trial was that Mumler was acquitted, as imposture was not proved against him. Faint ghost-like pictures may be produced upon imperfectly cleaned glass plates treated in a peculiar way known to scientific photographers, so a favourite explanation of the case in the photographic

journals when the trial was over was that ghost-like smudges were thus produced, and imagined to be likenesses of departed friends by weak-minded purchasers. But when the photographs themselves reached England, it was seen that the phantom faces were well-defined absolute likenesses, presenting marked features. To still further complicate the matter, some witnesses testified that these pictures came out in Mumler's presence in the operating rooms of other photographers where Mumler was not allowed to touch the glasses, chemicals, or sitters. Up to this point the case was puzzling enough, but very recently the "British Journal of Photography" published a part of a letter from Mr. S. C. Hall, F.S.A., Barrister-at-Law, which had been written about the Mumler case to Judge Edmonds, an eminent man who defended Mumler and believed in his innocence. In this letter Mr. Hall said that he and eight witnesses all at the same time saw the spirit of his sister at a circle, Mr. Daniel D. Home being the medium. Among the eight witnesses was the Hon. Mr. Lindsay. The spirit, he said, was visible for about two minutes, and stood out palpably and distinctly enough to be photographed had any photographer been present with his apparatus. So stands the evidence at the present time respecting the Mumler case, whilst that remarkable photographer himself is now at large producing his spirit pictures and loudly offering to submit to any reasonable investigation of his powers. Can he not come to England?

M. Jamin, of Paris, has invented a new polarising prism, but no specimen, so far as we know, has as yet reached England. It consists of a glass box filled with bisulphide of carbon, and a slice of Iceland spar is placed diagonally in the centre of the box.

After reading the correspondence called forth by the publication of Mr. Sutton's new process, it seems to us that a new principle in photographic science has been discovered, without any of the writers having noticed the fact. Major Russell says that Mr. Sutton's prepared plates contain a large amount of soluble bromide. Now with any ordinary preservative this bromide would have to be for the most part removed, or the plates would be very insensitive. But Mr. Sutton does not so completely remove it, yet on pouring a weak alkaline solution containing traces of organic matter over the plate, great sensitiveness of the film is said to be the result. If so, we have the new discovery that alkalinity of the organifier will give sensitiveness to a film containing a large amount of soluble bromide. As yet no evidence has been published supporting Mr. Sutton's opinion that his new process is far more sensitive than the wet one, and upon this point all its value depends. It is to be hoped he will soon send to London pictures of street scenes, giving abundance of half-tone and sharpness in moving figures. When practical photographers see that he can produce much better instantaneous pictures than they themselves can by the wet process, Mr. Sutton's fame will be established.

NOTICES OF BOOKS.

THE proceedings of the British Association have occupied so much of our attention and space for the last few weeks as to prevent our noticing some very useful books which have come to hand since our last notice. They have therefore accumulated to the number of a round dozen, and are now about to receive the attention they demand. We will first notice a valuable addition to engineering literature, which has been made by Professor Rankine. This is a manual of machinery and millwork,* and which forms the fifth of a series of practical manuals on civil engineering and mechanics by the same author. The volume before us is divided into three main sections, the first of which treats of the geometry of machinery. In this section are given elementary rules in descriptive geometry, after which the motions of the primary moving parts of machines are described. The motions of secondary moving pieces are then considered, and the elementary and aggregate combinations in mechanism are fully and lucidly explained. The second part of the work is devoted to the dynamics of machinery, and includes a notice of the performances of work by machines, dynamometers, regulating apparatus, &c., being here considered. The third division is occupied by particulars relating to the materials used in machinery—general tables of strength of materials being given—to the construction of machinery, and to the principles relating to strength and stiffness of machines, the principle of the action of cutting tools being also explained. The author solves several problems in mechanism by methods which have not hitherto been published, but which are notable for ease and accuracy. We may specially refer to the drawing of rolling curves and of some kinds of cams, the construction of the figures of teeth of skew bevel wheels and of threads of gearing screws by the help of the normal section. There are also some improvements in the details of processes for designing intermittent gear, link motions and parallel motions. The text is interspersed with numerous diagrams, and the whole forms a volume in no way behind those of the series which have preceded it. It fully sustains the reputation of its talented author, and will take its place as a high class text book of mechanics.

* "A Manual of Machinery and Millwork." By WILLIAM JOHN MACQUORN RANKINE, C.E., LL.D., F.R.S., &c., &c. London: CHARLES GRIFFIN and Co., Stationers' Hall-court. 1869.

We next come to a new edition of Mr. Bourne's recent improvements in the steam engine,* which was first issued as a supplement to the Catechism of the Steam Engine, by the same author. This useful book gives a clear and concise idea of the various improvements which have been made of late in the steam engine in its various applications to mines, mills, ocean navigation, railways and agriculture. In the present edition several examples which appeared in former editions have been omitted, and they have been judiciously replaced by many new examples. Amongst these will be found some of the most remarkable engines collected in Paris at the Exhibition of 1867. The volume has been much enlarged upon its predecessors, and contains descriptions and illustrations of every class of engine, as well as some useful remarks upon superheated steam, boilers, furnaces, the injector, slide valves, pumps, &c. A variety of examples of locomotive engines are given, but we miss one which we think ought to have found a place in such a work as the present. This is Mr. Fairlie's system, which, as is well known to our readers, has been brought to a practical issue by the inventor. But if this has been overlooked, our author has taken care to supply examples of the most recent practice in steam fire engines, as well as in hot air engines. This renders the book very complete, and will make it most useful for reference for some time to come—that is, until the changes brought about by the rapid progress of mechanical engineering render another edition necessary.

A work which will find favour with students, and will prove very useful to general readers, has just been given to the public by Dr. Nuttall.† It is a dictionary of scientific terms, and it makes its appearance at a very opportune moment, when the question of technical education is taking such a practical turn. The language of practical science is here elucidated and rendered familiar to the general student. By the aid of this useful volume, both he and the general reader may readily ascertain the derivation, meaning, and general application of the numerous words which are being brought into daily use by the progress of scientific knowledge.

* "Recent Improvements in the Steam Engine." By JOHN BOURNE, C.E., new edition. London: LONGMANS, GREEN, and Co. 1869.

† Dictionary of Scientific Terms. By P. AUSTIN NUTTALL, LL.D. STRACHAN and Co., 56, Ludgate-hill. 1869.

The recent proposition to abolish the Patent Laws called forth observations and indignant protests from many quarters. Amongst others, Mr. Henry Dircks has addressed a letter to Lord Stanley, and which has been published in pamphlet form by Messrs. E. and F. N. Spon, 48, Charing Cross. In this letter, Mr. Dircks ably shows up the fallacies of Mr. Macfie's statements in the House of Commons. Mr. Dircks very properly contends that the whole question in dispute affecting the abolition of the Patent Laws concerns only manufacturers, and not the nation at large—the public, the million. The people, says Mr. Dircks, never will move in it, simply because they are the gainers, even although some few manufacturers, with old works conducted on old systems, may happen to suffer ever so much during some great reform; such as, for example, the substituting of steam engines for atmospheric machines, doing away with spinning jennies, introducing steam propulsion on land and water, or whatever interferes with supposed vested rights. And, after all, when thus limited to manufacturers, how few are ever affected to their serious injury, and how many owe their elevation to their early enterprise in the encouragement they have given to some patented novelty. Those who argue against Patent Law never keep to one argument, never prove anything. They assert abundantly that it is a national calamity by which trade is hampered and the progress of manufactures impeded. These are their public grounds of groundless complaint. Then they shift to the poor inventor: he has only an idea, he can have "no property in ideas," his law expenses are enormous, patents ruin him, the true inventor gets no benefit, and so forth, to prove that patenting of inventions is a delusion and a snare! Then come their comparisons. Mr. Macfie stated that "an invention differed altogether from the literary work of an author, which he would continue to protect." So that, logically stated—a book not being an idea, a man may legally claim a property in his book! Such, says Mr. Dircks, is the miserable reasoning of the opponents of equal protective right in works of genius and talent.

Another tunnel scheme for crossing the Channel, and thus placing England and France in direct communication, has been worked out by Mr. E. W. Young, C.E. (Messrs. Spon). Mr. Young proposes to construct between Dover and Cape Gris Nez a wrought-iron tunnel, in short sections of (say) 200ft. to 300ft. in length. These are to be floated into position and lowered into place at a certain depth below the surface of the water, where, the joints being made good by divers, they would form one continuous tube across the Channel. The tube being buoyant, would be held down to the required depth by mooring cables of iron, attached to blocks of bêton of sufficient weight. The tube would be fixed at such a depth below the surface as to be practically unaffected by the waves. It could not be raised vertically without lifting the anchors or breaking the mooring cables, nor depressed without overcoming its buoyancy. It could not mov laterally without breaking away from the inclined mooring cables, and, therefore, it would be stable under all circumstances Ventilation would be secured by means o lighthouses placed half a mile apart along the tube. These lighthouses would be supported from the bottom of the sea by piers formed of clusters of cylinders filled with concrete. Mr. Young gives drawings and details of his proposition in the pamphlet before us.

Four useful little volumes are to hand from Messrs. Cassell, Petter, and Galpin, of La

Belle Sauvage-yard, London. The first is Tyndall's Natural Philosophy, which has been brought down to the level of the most ordinary understanding, and is produced in the form of easy lessons. These lessons will be found an acquisition to schools as well as to the student who is setting out on the path of scientific inquiry and research. The second volume is an elementary treatise on building construction, by Mr. Ellis A. Davidson, and forms the third of the series of Messrs. Cassell's technical manuals. This book gives a general knowledge of the principles of building construction, and at the same time affords elementary practice in architectural drawing. It is illustrated by 133 wood engravings, and, as an elementary work, will be found exceedingly useful. The two remaining books received from this enterprising firm are "Æsop's Fables" and "Evenings at Home." They are both reading books for beginners, and have been written in words of one syllable—the "Fables" by Mary Godolphin, and the "Evenings" by Uncle John.

Some interesting "Notes on the Geology of North Shropshire," by Charlotte Eyton, have been published by Mr. Hardwicke, 192, Piccadilly. The authoress puts forth her "Notes" with much modesty, but she may rest assured that they will be appreciated by all who take a geological interest in the district, as well as by beginners in the study of geology. The book is simply a collection of notes of geological work in the neighbourhood of the Wrekin and part of the plain of North Shropshire. Each chapter interests whilst it teaches, and this little *brochure* will afford pleasant reading to all who feel sufficiently interested in geology to give it a perusal.

Those who think will find much good food for thought in "Lacon," which was addressed to them some years since by the Rev. C. C. Colton, M.A. A new edition of this work has been published by Mr. Trounce, of 9, Cursitor-street, Chancery-lane. This book deals with a variety of subjects of a moral and religious character, but hitherto it has had one drawback to its utility. This was the absence of a means of ready reference to any particular anecdote, maxim, or position, an abundance of all of which it contains. In the present edition, however, this defect has been remedied, the editor having prepared a brief, but expressive, title for each article, which is prefixed to it. An index also has been added, which is a further great improvement in a volume containing about a thousand distinct subjects. Thus the most popular of the rev. author's works has been made increasingly useful to those who can snatch half an hour now and then from busy life for thought and reflection.

A fellow of the Meteorological Society has written a pamphlet on the aneroid barometer, with instructions for its purchase and use (Houlston and Wright, 65, Paternoster-row. 1869). It describes the construction of the aneroid, and points out its usefulness. The author gives the new altitude tables by the Astronomer Royal, and illustrates his subject by engravings of aneroids of various kinds and suitable for various purposes. The pamphlet, of course, is written in a popular style, and will be found useful for its intended purpose.

Messrs. Longmans and Co. have issued a second edition of their "Monarchs of England since the Conquest." It is arranged in a compact tabular form, about 11in. square, and shows at a glance many particulars relating to each sovereign. Advantage is taken of the principle of association of ideas to enable the main facts to be retained in the memory for any length of time.

ELECTRICITY AND TELEGRAPHY.

PROFESSOR FLEEMING JENKIN has recently patented some improvements in obtaining electric light. His invention is especially applicable to beacons and buoys, which by its use may be lighted by a voltaic battery placed on shore and communicating with the beacon by a submarine cable. The light is produced by a rapid succession of sparks due to successive charges and discharges of a condenser charged directly from a voltaic battery without the intervention of any induction coil. When the system is used for this purpose, the condenser is on the beacon, and the battery on shore is connected with a terminal on the beacon by a submarine cable or aerial wire. The condenser is charged and discharged by a tongue or contact maker moving backwards and forwards between the battery terminal and an earth terminal. A somewhat similar plan has been adopted with a Rhumkorff induction coil, but the new apparatus dispensing with the induction coil is less likely to get out of order, and converts a considerably larger proportion of the energy of the battery into light. The motion of the tongue is produced by clockwork driven by a spring, which, says the Professor, may be wound up in some cases by the motion of the buoy or beacon, as self-winding watches are wound. The motion of the tongue may also be produced by currents sent from shore through a second wire, which would move the tongue by an electro-magnet, as the tongue of a relay is moved in the usual Morse instruments. The tongue might also be moved by the motion of the buoy in some cases; it might also be worked in a manner analogous to the trembleur of the ordinary bells. To prevent the contacts where the sparks pass from wearing away too rapidly, the contact pieces are made to revolve slowly, so as to distribute the action over a large surface.

In the prospectus of the proposed "Land and Sea Telegraph Construction Company (Limited)," it is stated that "Mr. Rowett is the patentee of the only deep sea hemp-covered cables now in use, the Atlantic cables being made on his principle," and that "Mr. Rowett has agreed to grant to the new company an exclusive licence for manufacturing cables according to his patent on moderate terms." These observations, which, it will be remembered, formed the subject of discussion in the MECHANICS' MAGAZINE a few months since, have called forth the following remarks from the solicitors for the Telegraph Construction and Maintenance Company (Limited), who manufactured and laid the three existing Atlantic cables. They protest against the first of these statements. With the second they say they have no concern further than to state, for the information of the public, the following facts respecting the alleged invention:—Mr. Rowett's patent is dated April 10, 1858, and his specification lodged on that day states that the invention principally consists in a method of regulating the specific gravity of electric telegraph cables, so that they shall possess a semifloating quality, and that this is to be effected by making the cables of Indian grass fibre, New Zealand and Manilla hemp cotton or cotton fibre, &c., and not theretofore employed in the construction of electric cables, and to pass the yarn or strands of the cable through a solution of turpentine, tar, &c., and in the centre of the cable thus made the necessary insulated wire is to be placed. In 1852 (six years before Mr. Rowett's patent) a light hempen cable, saturated with a solution of some of the materials described by him, and covering two insulated metal telegraph wires, was laid between Port Patrick and Donaghadee. In 1855 and 1856, at least six different specimens of telegraph cable, having an outer covering of hemp and iron on precisely the same principle as the three Atlantic lines, were made by the Gutta-percha Company, and publicly tested in September, 1856, at Messrs. Brown, Lennox, and Co.'s works, for the scientific committee appointed to decide the best form of cable for the Atlantic Telegraph Company. The committee chose the former, which was actually adopted, and which has proved so signally successful, but which, nevertheless, Mr. Rowett has on many occasions declared to be altogether wrong in principle. A piece of the hempen cable of 1852, and several of the specimens of 1855-6, are now in our possession. Mr. Rowett has frequently been informed of these facts. It is of importance to the Telegraph Construction and Maintenance Company that their shareholders and the public should understand that this company can still make and lay cables of the Atlantic pattern, notwithstanding the "exclusive licence" granted by Mr. Rowett to their new rivals.

The telegraph cable between Caithness and Orkney was successfully laid in the Pentland Firth on Monday last. The distance across the Firth is eight miles, and the time occupied was only two hours and a half.

The number of messages which passed over the French Atlantic cable for the week ending September 11 was 478, the cable charge on the messages amounting to £1,068.

NOTES ON RECENT DISCOVERIES IN SCIENCE AND THEIR PRACTICAL APPLICATIONS.

A MERCURIAL DYE—A NEW WAY OF WATERPROOFING FABRICS—TO MAKE INDIARUBBER TUBING IMPERMEABLE TO GAS—GAS FROM SEWAGE—AN EXTRACT OF VEGETABLES.

M. BRETONNIERE has brought into use a new grey dye, in one particular a novelty. In this country we have employed a solution of a salt of lead to saturate a fabric or yarns, and havethen either exposed the material to an atmosphere of sulphuretted hydrogen or immersed it in a solution of a sulphuret, and so obtained a solid lustrous grey. The colour, however, was never a favourite. M. Bretonniere, in place of a salt of lead, uses a salt of mercury, the nitrate, for example, and so will obtain just about the same colour. The dye is not so expensive as might be thought, for very dilute solutions may be used unless deep shades are required. It might be thought dangerous to go about with a dress saturated with a compound of mercury, but we are told that no evil effects have been known to follow. We would not recommend the dye for stockings, for, although sulphide of mercury is insoluble, by long contact with the skin soluble compounds may be formed, and the effects of mercurial poisoning might be produced.

M. Neuman has discovered a new way of waterproofing—or rather of making fabrics impermeable to water. The operation is simple, but it must be carried on with care, or the fabric will be ruined. It consists in submitting the tissue it is wished to make impermeable to the action of moderately strong sulphuric acid (57deg. Beaume) for a space of time varying from a second or two to two minutes according to the nature of the fabric. By the action of the acid the fibres, whether of wool or cotton, are superficially decomposed into a glutinous material. As soon as this has happened (the time required must be found by experiment) the fabric is passed rapidly through water, and well rinsed and finally dried, first in the air and then over cylinders. The glutinous matter will of course fill up all spaces between the threads, and no doubt the fabric will be made impermeable. Another way of effecting the same object is to completely dissolve cotton or linen in sulphuric acid and spread the solution over the fabric either by means of cylinders or a brush. Calendering seems to be advisable in both cases.

Indiarubber tubing is slightly permeable to gas. As a fact, the amount which escapes through the walls of the tube is very small, but there are places in which it may be advisable to render any escape impossible. This can be done by giving the tubing a thin coating of a varnish made by dissolving one part and a half of treacle and two parts of gum arabic in seven parts of white wine and three and a half parts of strong alcohol. That is the receipt of M. Jouanne, but we have no doubt that beer may be substituted for white wine without harm. The treacle and gum must first be dissolved in the beer or wine, and the alcohol must be added very slowly, constantly stirring the mixture, or the gum will be thrown down.

It is not a recent discovery in science that gas can be obtained from sewage, but the fact has lately been published as a novelty just discovered in India. The wonderful news comes too that it is proposed to light some of the larger Indian cities with gas from this source. As a matter of course, it is suggested that we should do the same, and the sewage difficulty is solved. What was darkness is now light. Waste is turned into profit. It is too bad, as we have said before, to delude the unfortunate metropolitan ratepayer in this way. Everybody who knows anything about sewage is well aware of the fact that it undergoes a sort of fer-

mentation, during which a good deal of marsh gas is given off. By precise experiments, it has indeed been determined that four cubic feet of ordinary sewage will, every twenty-four hours for about a week, give off a cubic foot of gas, more than three-fourths of which will be marsh gas. It is mixed with nitrogen, carbonic acid, and sulphuretted hydrogen. The mixture will burn, but it is unnecessary to say with a very faint light. For illuminating purposes, such gas would be worthless; but it is simply the discovery of this gas, we imagine, that has excited the bright dreams of a sanguine writer in the "Pall Mall Gazette." As regards the extent and nature of the works which would be required, we need only say that to furnish London with gas sufficient for one night's consumption it would be necessary to store in close vessels a week's sewage, estimated at 28 millions of tons.

That an extract of vegetables should follow an extract of meat is very natural, but we are somewhat astonished at the form in which we are told it is obtained. It is said to be a limpid colourless liquid, which contains the flavour and aroma of all the more commonly used vegetables. The process by which the extract is made is not yet made public.

PROCEEDINGS OF THE BRITISH ASSOCIATION.

SECTION B.—CHEMICAL SCIENCE.

ON A SPECIMEN OF OBSIDIAN FROM JAVA, WITH A MICROSCOPICAL EXAMINATION.

BY MR. W. C. ROBERTS.

MICROSCOPISTS have lately urged the necessity and importance of examining rock sections with the microscope. Little, however, appears to have been done in the accurate identification of the constituent minerals of the rock mass. The present paper was a statement of the result of the examination of a substance that, from the indefinite character of its composition, partakes of the nature of a rock rather than that of a mineral. It consists of a specimen of obsidian from Java, originally in the cabinet of Bernard Woodward, Esq., but the label does not give the exact locality. It appears to differ much from that, also from Java, now in the British Museum. The specific gravity of the specimen now produced is 2·35; in thin sections it is perfectly transparent. The lecturer gave a complete analysis of its composition, which he said may be easily cut into thin sections, and by the aid of a low power, say 200 diameters, at least three distinct minerals (beautifully crystallised) may be distinguished, diagrams of which were produced with the specimen. These, with the optical properties, were admirably described, some doubt being expressed as to the nature of the second mineral; but the third was undoubtedly composed of magnetic iron.

ON THE ACTION OF HYDRIC-SULPHATE ON PHOSPHORIC-CHLORIDE.

BY MR. STEPHEN WILLIAMS.

THE action of hydric-sulphate on phosphoric-chloride holds an important place in the history of chemical theory since Professor Williamson, by interpreting it aright, fully established the debasic character of hydric-sulphate. About fourteen years ago, Professor Williamson discovered that the first product of the action of phosphoric-chloride on hydric-sulphate was a body which he termed chlor-hydrated sulphuric acid, and that the second step of the reaction was the formation of chlorosulphuric acid. Gerhardt had performed this same experiment, but had misinterpreted the results. Having obtained a fuming liquid, he seems to have concluded that it could only be sulphuric acid, and he explained the reaction as though the first step was the removal of the elements of water from the hydric-sulphate by the phosphoric-chloride, and then the decomposition of the sulphuric acid. It was afterwards attempted by diffusion to separate the hydric-chloride and sulphuric acid, and many forms of apparatus were used, but unsuccessfully. One reaction of this chlor-hydrate is worthy of notice. It was found that when added to hydric-sulphate, it breaks up hydric-chloride, being expelled with great violence. From this we see that the attraction between hydric-sulphate and sulphuric acid is greater than that between the hydric-chloride and sulphuric acid in the chlor-hydrate.

SECTION C.—GEOLOGY.

ON SCHEELITE.

BY MR. C. LE NEVE FOSTER.

THIS was a paper on the occurrence of the mineral *Scheelite* (tungstate of lime) at Val Toppa Gold Mine, near Domodossola, Piedmont. In this paper the author stated that *Scheelite*, or tungstate of lime, is now occurring at the Val Toppa gold mine. It is associated with quartz, iron pyrites, zinc blende, calcspar, brown spar, and native gold; whilst wolfram, tinstone, molybdenite, fluor-spar, apatite, topaz, and tourmaline, which usually accompany *Scheelite*, are entirely absent. The *Scheelite* is called "marmor rosso" by the Piedmontese miners, and is looked upon as a good indication for gold. Professor Warrington Smyth said this rare mineral might be found in the neighbourhood of Tavistock, in Devonshire.

ON CERTAIN PHENOMENA IN THE DRIFT, NEAR NORWICH.

BY MR. J. E. TAYLOR.

IN this communication, Mr. Taylor said that, although there was the finest series of the Drift beds in Norfolk to be found in Great Britain, still in the Upper Boulder clay certain anomalies occur which frequently puzzle the geologist. The paper was an attempt to explain these by referring them to the agency of icebergs. Sometimes there were found beds of Upper Boulder clay lying at lower levels than the Middle Drift beds. In fact, such phenomena occurred through icebergs having ploughed up the sands and deposited beds of clay in the furrows. This accounted for the out-of-the-way character of what had been termed "Third, or Valley Boulder clay." The sand beds on each side these linear extensions of clay were frequently dragged out of their place and contorted. The chalk also was disturbed and the flint bands thrown into almost perpendicular positions in the neighbourhood of such phenomena. Mr. Taylor also mentioned the exceeding narrow track of these abnormal beds of clay, and concluded by showing that their occurrence only the more fully bore out the glacial hypothesis.

The President, Professor Harkness, said Mr. Taylor distinguished himself by working on the Cray and Drift beds of Norfolk, and that his paper was very valuable and interesting. He then traced the general relationship of the Lower and Upper Boulder clays, and of the Middle Drift beds. The first and last, he said, always showed strong evidences of ice action and arctic climature, the Middle Drift sands being marked by having numbers of non-arctic shells and flint pebbles. Professor Harkness reviewed the various localities where this was the case, both in England, Ireland, and Scotland.

Mr. S. Pattison, F.G.S., said similar phenomena to those mentioned by Mr. Taylor could be seen in the neighbourhood of Whitby. He had no doubt they were due to iceberg groovings.

FRESH-WATER DEPOSITS OF THE VALLEY OF THE RIVER LEA, IN ESSEX.

BY MR. HENRY WOODWARD, F.G.S.

CERTAIN excavations made by the East London Waterworks Company had revealed the presence of shell marl on the Walthamstow Marshes. The marl was accompanied by vegetable remains and bog iron ore. All the shells are recent, and the most notable fact connected with the bed was the presence of bronze spear-heads, arrow-heads, knives, &c. These were accompanied by bones of man, wolf, fox, beaver, wild boar, red deer, roebuck, fallow deer, reindeer, &c., as well as of the sea eagle, and fishes. As late as the year 1700, the entire tract was forest land. In 1154, the same country is described as abounding in wolves, wild boar, wild bulls, &c. Mr. Woodward thought that the maintenance of a Royal Forest had been the means of preserving this bed. In the deep cutting of the bed, remains of the mammoth were met with. The author thought much of the deposit might fairly be ascribed to the beaver working and making dams in the old valley of the Lea.

Mr. Pattison said the implements were found in the upper or historical portions of the beds mentioned.

Mr. Woodward, in reply, said the discovery of the beaver, red deer, and reindeer within seven miles of London was something astonishing.

THE SOURCE OF THE QUARTZOSE CONGLOMERATES OF THE NEW RED SANDSTONE OF CENTRAL ENGLAND.

BY MR. EDWARD HULL, F.G.S.

THE author referred to a supposed statement of Dr. Buckland that the quartzite pebbles of the New Red Sandstone had come from the rocks of the Lickey, in Worcestershire. That geologist, however, only said they were very similar to them. Mr. Hull then proceeded to trace the probable origin of these pebbles. In South Lancashire and Cheshire, these conglomerates attained a thickness of 600ft. and 700ft. They were thicker as we proceeded northerly, and the author therefore thought we ought to look in the latter direction for their source. He produced pebbles from various counties, all of them liver-coloured quartzites. One peculiarity about them was their well-rounded, water-worn form, never sub-angular. The author thought that these pebbles had gone through at least two periods of trituration, and he had some time ago come to the conclusion that all were originally derived from the Old Red Sandstone formation. This idea was verified when he went to study the old red conglomerates near Loch Lomond; and he thought the question of the origin of the new red conglomerates of Central England might now be regarded as settled.

Mr. Maw, Mr. Pengelly, Mr. Godwin-Austen, and Professor Huxley then continued the discussion of the subject, Mr. Austen objecting to the idea that a great amount of time is required to produce well-rounded shingle.

Professor Huxley objected to the idea that a shingle bed could thicken seawards.

NOTES ON THE BRACHIOPODA, HITHERTO OBTAINED FROM THE "PEBBLE-BED" OF BUDLEIGH SALTERTON.

BY MR. T. DAVIDSON, F.G.S.

THE author had examined the specimens forwarded to him by Mr. Vicary and others. None of the rocks known to occur in England presented such a fauna, although in Normandy we have a bed of Silurian rock extant containing the same. Mr. Davidson could not account for the extraordinary mixture of Devonian and Silurian forms, except by supposing that some old land had been broken up. There were ten Silurian, ten Devonian, and fifteen undescribed species of brachiopoda.

Mr. Winwood, Mr. Vicary, and Mr. Godwin-Austen afterwards spoke on the subject, the latter gentleman entering into a popular detail of the occurrence of these fossils.

Mr. Salter was of opinion that when these "pebble-beds" were formed there was no break between England and Normandy. The fossils were derived from rocks which occur nowhere else than in Normandy.

Mr. Davidson thought that at least one half of the fossils found in the pebbles had been derived from local sources.

Mr. Austen said that Lower Silurian fossils were found on the south coast of Cornwall.

Mr. Pattison thought that the remarks which had been made only bore out the theory of Mr. Godwin-Austen, that a reef of palæozoic rocks had formerly stretched across what is now the English Channel.

Mr. Etheridge pointed out that the Budleigh pebble-bed lay on the triassa of Teignmouth, and thought that the pebbles had come from Normandy.

SECOND REPORT ON BRITISH FOSSIL CORALS.

BY DR. P. M. DUNCAN.

AFTER describing many new species, and noticing the 140 kinds already published, the author stated that 251 species of corals had been found in British Secondary and Tertiary strata. The presence of certain kinds of corals in strata was shown to indicate peculiar conditions of sea water. The report concluded with a statement concerning the periods when the area of England was occupied by an ocean with coral reefs, or by moderately deep seas and shallows. The condition of this area was then compared with that of the continent during the Secondary and Tertiary periods, and it was shown that coral reefs fringed the old coast line.

REPORT OF COMMITTEE ON PHOTOGRAPHS OF CORALS.

BY MR. J. THOMSON.

THE author of the above paper has devoted considerable time to cutting very thin sections of fossil corals, and afterwards photographing them. This method has afforded palæontologists a natural means of studying the structure of these interesting fossils. When mounted on glass these sections can be magnified to any extent by the oxy-hydrogen lantern, and thus these old world forms, which are of great beauty, can be made to illustrate their own history.

THE GRANITE OF THE NORTHERNLY AND EASTERNLY SIDES OF DARTMOOR.

BY MR. G. W. ORMEROD, F.G.S.

THIS short paper was intended to serve as a guide

to geologists visiting Dartmoor. Scheel and tourmaline are of frequent occurrence in the granites. South of Torquay are rock basins of various shapes and sizes. Throughout the whole of Dartmoor the granite is much jointed, and sudden changes in the joints and stratification frequently occur. On the north of Dartmoor, near Belston, the granite bends under schistose rocks, and the present contour of the country may be attributed to this phenomenon. It was an uncertain point whether the Dartmoor granite was all of one age, but the "elvans," or veins crossing the mass, were of undoubtedly later age. A vein of fine porphyry may be seen on the road from Okehampton to Exeter.

Mr. Ormerod said geologists visiting Dartmoor could not help asking what had become of the overlying rock masses, and what had been the agents which had cut it down to its present form. Mr. Pengelly had stated that some of the beds in the Isle of Wight had been formed out of the wear and tear of the granites of Dartmoor. The author had not found any glacial scratchings, but last year Professor Otto Jorell had visited with him the gravels near Hunt's Tor, and that geologist had declared it as his firm opinion that these were remains of *moraines*.

THE DEVONIAN GROUP CONSIDERED GEOLOGICALLY AND GEOGRAPHICALLY.

BY MR. GODWIN-AUSTEN.

THIS paper dealt with the probable distri bution of land and water during the Devonian period, its fossil zoology and botany, and the physical changes which have taken place subsequently.

Mr. Austen briefly and popularly sketched the order of successive sea-beds, and showed that these represented geological time. Of these the Devonian group were amongst the earlier. Our rocks, sandstone, or otherwise were simply sea bottoms, and the geologist only referred them to their original condition in order that he might deduce their physical and zoological history. The Devonian rocks had a wide geographical extent, in Europe, Asia, and America. In the latter country there was a broad band of old Silurian rocks, which existed as dry land during the Devonian epoch. In Great Britain the Devonian rocks had a general direction from north-east to south-west. From the nature of the fossil fishes of these rocks, Mr. Austen came to the conclusion that the Old Red Sandstone was of fresh water origin, as of all the existing fishes, only six genera were related to the Ganoid family, and all of these were of essentially fresh water habits. The dry land was covered with a series of great fresh water lakes, like those of North America. Besides the strata deposited along the bottoms of these lakes, there was a series of vast marine deposits, which are termed Devonian. The Old Red Sandstone group was a very perplexing one, and passed down into the Silurians at its base, and into the carboniferous towards its upper portion. The most northern portion of this county, where rocks containing true Devonian fossils came up, was Linton. The author then traced the easterly direction of the Devonian group, showing how they cropped up beyond the chalk of Boulogne, and thence across Belgium and Prussia, into Bohemia and Russia.

Professor Phillips said the division of Old Red Sandstone as fresh water, and Devonian as marine, made by Mr. Godwin-Austen, was very distinct. The former extended towards the north, and the latter towards the south. He expressed himself, however, as opposed to the fresh water origin of red sandstones, simply because few fossils were found in them.

Mr. Pengelly said he had found 300 specimens of Pteraspidian fishes in the Devonian rocks, as well as cephalopoda.

Mr. Edward Hull, F.R.S., expressed his hope that geologists would withhold their decision on Mr. Godwin-Austen's separation of the Old Red Sandstone and Devonian, and pointed out the three sub-divisions of these formations in various places. He thought the evidence of fossil fish was not sufficient to establish the fresh water origin of Old Red Sandstone.

SECTION D.—BIOLOGY.

DEEP SEA DREDGING.

BY PROFESSOR WYVILLE THOMPSON.

THIS was a communication from the learned Professor which was read by the Rev. A. M. Norman, F.L.S., on the successful dredging of H.M.S. "Porcupine," in from 2,435 fathoms. The Rev. A. M. Norman prefaced the letter by a statement of what had been done recently in deep-sea dredging, observing that the work of prosecuting deep-sea researches must be carried on by Government on a very large vessel and the highest skill in navigation on the part of the officers and very costly apparatus. The late Government had taken up the matter, and dredging expeditions were organised in the Atlantic Ocean, which had been attended with the most important results. The remarkable extension of knowledge in this direction had removed the idea which, started by the late Professor Forbes, had prevailed till very recently, that marine life did not exist at depths beyond 300 fathoms. That was a most remarkable illustration of the necessity for caution in coming to conclusions. If Professor Forbes, the greatest marine zoologist of his time, could fall into such an error, how careful need everyone be in coming to conclusions. Some interesting results had been obtained by Professor Percival Wright off the coast of Spain; and at the instance of the Royal Society, H.M.S. "Lightning" had been sent out to dredge in the sea between the Hebrides and the Faroe Islands, and one result was to find that there were two distinct sets of temperatures and two sets of fauna within 50 miles; that difference of temperature was probably caused by the return of the waters of the Gulf Stream after being cooled at the Pole. The investigations of the "Lightning" had only been carried to the depth of 650 fathoms, and found no life at that depth. Professor Thomson had, however, dredged in the Bay of Biscay to the depth of 2,800 fathoms, and the letter gave an interesting account of the casting of the dredge at such depth. About 1½cwt. to 2cwt. of ooze was the general result of a cast of the dredge, and the thermometric instruments employed showed the temperature to be about 36·4, and life was distributed over the whole area which had been examined before the specimens were of a dwarfed character, owing, probably, to the low temperature.

In the course of the discussion which ensued, Professor Huxley said he hoped it would not be at once assumed that naturalists had assumed Professor Forbes's inference as to the depth at which life might be expected to exist. No revolution had taken place in science on account of the recent dredgings. Men of science, and even Professor Forbes himself, were too well aware of the unsatisfactory nature of the merely negative evidence, of which they were always distrustful. The fact was, that such statements as that referred to by Mr. Freeman concerning Professor Forbes's theory got into the text-books of science, and were spoken of as scientific conclusions, when, in fact, nine-tenths of the writers of text-books were a sort of chiffoniers who picked up any kind of rag which they found lying about. They had often called that the conclusion of men of science when men of science had not, perhaps, ever thought of adopting it. He had recently had the opportunity of examining a quantity of soundings sent him by the Admiralty, which had been dredged in all parts of the world; and it appeared from these that there was a gigantic band of life encircling the globe at the bottom of the sea. It was, too, extremely interesting to reflect that the sea bottom in which these creatures were found was of the same geological formation as that which was millions of years old, and the forms of life found there also resembled those found in the geological formations, called the Cretacean period. It was almost impossible to realise their wonderful antiquity of origin. If the land of Prester John could be found and a colony of ancient Egyptians, identical in race, dress, and manners, as those whose pictures were to be found on the Pyramids, that colony would not be one-tenth as wonderful in point of antiquity as were the forms of life found at these great depths of the sea.

Dr. Hooker also pointed out that Professor Forbes's theory had never been accepted as deductions, and alluded to the dredgings of Sir James Ross in 1842-3 at 400 fathoms deep.

The Rev. A. M. Norman, in reply, disclaimed all intention of putting forward the supposition of Professor Forbes as a scientific deduction, and called the attention of the associate members at least to the necessity for observing the distinction between soundings and dredgings, as it was the latter which had been of the greatest importance, as they had furnished the materials which had illustrated so many interesting facts of modern science.

THE PRIMITIVE CONDITION OF MAN.

BY SIR JOHN LUBBOCK.

THIS was a long and interesting paper, which, the author observed, was in reply to certain remarks made by the Duke of Argyll upon a paper read by him (Sir John Lubbock) at the Dundee Meeting of the Association, on the civilisation of the primitive condition of man. The hon. baronet said that the Duke of Argyll, whose speculations on the primitive condition of man first appeared in "Good Words," and were afterwards republished, had also attacked Professor Huxley for proposing to place man and the quadrumana in one order of mammalia, considering that, though this course would be justified if we considered the merely anatomical characters, it is precluded by the immense difference in intellectual power. This was, however, a dangerous argument, since, if man is to form an order by himself on account of his mental superiority, it will be impossible any longer to maintain the unity of the human species, since we must allow a proportionate weight to the immense differences existing between different races of men. The Duke of Argyll, although maintaining Whately's theory as to the primitive condition of man, abandoned the arguments by which, in the opinion of that eminent theologian, that theory mainly rested. Sir John defended himself from the criticism of the Duke of Argyll as to his looking upon all brutal customs as primeval, and showed that his grace had misunderstood his meaning and argument, which was, that a definite sequence of habits and ideas might be traced, and that certain customs still lingering in civilised communities were attributable to a state of former barbarism, rather, however, on account of their simplicity than of their brutality. The theory of the Duke of Argyll, that savages are "mere outcasts" of the human race, was then examined by the hon. baronet at considerable length, and the principal argument adduced against it was, the immense area which was till lately occupied by tribes in a state of barbarism, and it was shown that the Brazilians, occupying a rich fertile country, were lower than the Esquimaux tribes on the shores of the icy sea. In old times, the settlers of new countries, were not, in Sir John's opinion, "mere outcasts," but men of energy and enterprise. The Duke of Argyll had maintained that the Tasmanians, who had no boats when discovered, must have originally possessed them, because they could not have walked over the sea. But the same argument would apply to the kangaroo, the echidna, and other animals, which inhabit both Australia and Tasmania, and whose presence proves a former land connection between these two countries. The Duke of Argyll had maintained that the character of the religion of the lower races of man offered no support to Sir John Lubbock's views, but the latter in his paper traced the course of religious thought, and showed that as man rises in civilisation he acquires a higher and truer conception of the Deity. Sir John also pointed to the remarkable similarity between savages and children. The history of the individual was the history of the race, and we might trace the gradual progress of civilisation in our homes. A clearer perception of this truth might have saved many a national misfortune, from the death of Captain Cook down to the Abyssinian war. In Sir John Lubbock's opinion this similarity between savages and children has so important a bearing on the question of man's primitive condition as to be almost conclusive. Sir John's illustrations were many of them very interesting, especially in regard to the comparison of the habits of children with those of savages, the savage's fetish taking a place between the baby and the child's doll, and the childish custom of tossing halfpence being found in existence amongst some of the primitive tribes in use as oracles.

SO-CALLED "PETRIFIED HUMAN EYES" FROM PERU.

BY THE REV. DR. A. HUME.

DR. SPENCER COBBOLD, for the author, read a paper on the discovery of what had been supposed to be petrified human eyes at Arica, in Peru. The region is exceedingly arid, and animal remains are not decayed, but dried, when put into the earth; and the communication stated that the corpses of Indians who had been buried before the Spaniards had landed were frequently to be found. In one part of Arica, near to where large numbers of people were known to be buried, a large number of eyes had been found. Some of these had been found near the corpses, and some, it was said, in the eye-holes of the skulls. A belief had prevailed that they were human eyes petrified; but on a collection of them being sent to Professor Owen, he pronounced them to be eyes of cuttle-fishes. Several were exhibited by Dr. Cobbold, and examined with much interest by those in the room.

SECTION F.—ECONOMIC SCIENCE AND STATISTICS.

RAILWAYS AND THE PUBLIC.

BY MR. RAPHAEL BRANDON.

MR. BRANDON in his paper contended that railway companies would prosper better than they do if they studied more the real wants and convenience of the public. The whole railways of the country ought to be under one general management, and railway facilities should be given as far as possible to any place requiring the accommodation. At the present moment the railways of the kingdom might be purchased at a large discount upon the capital expended upon them, showing that as an investment the railway speculation had been a failure. More than half the capital paid less than 5 per cent., and a considerable proportion paid nothing. Had the public obtained such advantage as to compensate for this great loss to the shareholders? He referred to the disadvantages arising out of competition and rivalry between companies, to the bad accommodation afforded to second-class passengers, and the studied annoyance and inconvenience placed in the way of third-class traffic, while statistics proved that the total receipts from third-class passengers were nearly as much as those from second and first class passengers together. He advocated the taking up of the railways by the Government. Then came the leading point in his scheme. He would charge three fixed sums, first, second, and third, for a journey, irrespective of the length of the journey, just as a letter is carried for a penny to the next village or to the most remote station. For example, a first-class passenger should pay 1s., second-class 6d., third-class 3d., for any journey. Mr. Brandon estimated that travelling would, in a short time, be increased to six times the present extent by such a change, and he entered elaborately into figures to show that his scheme would pay. He would allow certain fast trains—trains without third-class carriages, and trains making few stoppages—for those willing to make an extra payment for the privilege, and he would make an extra charge for luggage requiring the assistance of a porter and a separate carriage in a van. In enlarging upon the advantages that would accrue from his scheme, he made a great point of the fact that such increased facilities for travelling would regulate the supply and demand of labour, and immensely diminish pauperism by sending people out of employment to the localities where there was work to do.

Captain Galton said there was a fallacy in the calculations. As an example, if a train from London to Edinburgh carried 20 passengers at 3d., that would be a rather large number, and yet the 20 three-pences would nothing like pay the cost of the journey.

Sir John Bowring was an advocate of the proposal for placing the railways of the country under the management of the Government, and he not only went the whole way with Mr. Brandon, but he even thought it possible that the minimum fare might ultimately be less than that mentioned by Mr. Brandon.

Mr. F. Purdy expressed strong objections to the suggestion for placing railways under the management of the Government. As a rule Government work was done neither well nor economically. As a statistician, however, he thought Mr. Brandon's figures were correct, and not fallacious, as Captain Galton supposed.

Mr. James Brewin spoke in support of Mr. Brandon's scheme, and especially defended his statistics. Taking all the journeys made in Great Britain in a year the average distance of a journey was 21 miles, and the average fare 11½d.

Dr. Farr (who occupied the chair in the President's absence) thanked Mr. Brandon for his paper, which commended itself to his (Dr. Farr's) mind as a proposal likely to be of vast benefit to the nation, and at the same time it appeared to him to be practical. It was an important matter, demanding much consideration.

PROFESSOR GRAHAM, F.R.S., Master of the Mint, is, we are sorry to say, lying dangerously ill at his town residence in Gordon-square. The unfortunate gentleman was, about a fortnight since, attacked with inflammation of the lungs. This, however, was overcome by the remedial measures of his medical attendants, and exhaustion constitutes the dangerous element in his case at present. The answer to inquiries yesterday was to the effect that Mr. Graham was rapidly "sinking."

DAMP WALLS.

OUR attention has of late been called to the question of rendering the walls of buildings impervious to moisture. We have received letters upon the subject from correspondents who ask us to point out a remedy for the evil. We, therefore, gladly take the opportunity of making known to our readers that there is a remedy, at once simple and efficacious. This is a process invented by Mr. Frederick Ransome, and which is being successfully carried out in practice by the Patent Stone Company, East Greenwich. It consists in the employment of colourless mineral solutions which possess the property of forming an insoluble and indestructible mineral precipitate when applied to buildings. The deposit takes place not only on the surface of the material to which it is applied, but enters the body of the substance. The application of the solution in no way alters the colour of the material, a perfectly natural appearance being preserved in the building. The effect is permanent, neither atmospheric nor saline influences in the least degree affecting the indurating material. It not only renders the building waterproof, but it further most effectually indurates and preserves from decay the stone or bricks treated with it. This process has recently been applied to several buildings which are stated to have been untenantable, previously to the application, on account of exposure to a wind-driven rain. Paper now hangs well on the walls from which it formerly drooped in festoons and tatters, whilst dryness and a cleanly appearance have taken the place of dampness and mildew. This process of rendering buildings impervious to wet is comparatively inexpensive, therefore no one need longer to suffer from that source of discomfort and danger to health—damp walls.

WHITWORTH SCHOLARSHIPS.

THE following is a list of the successful candidates, with their ages, occupations, and the number of marks they obtained, who have been reported to the Science and Art Department as entitled to the ten Whitworth Scholarships of £100 a year each:—William H. Greenwood, aged 23, engineer student at the Mechanics' Institution, Manchester, 143 marks; Thomas A. Hearson, aged 23, engineer student, Royal School of Naval Architecture, 137 marks; John, B.Sc., Hopkinson, aged 19, student at Cambridge University, 134 marks; Thomas S. Elgood, aged 24, mechanical engineer, Leicester, and Owen's College, Manchester, 127 marks; George A. Greenhill, aged 21, student at Christ's Hospital School and Cambridge University, 116 marks; John R. Brittle, aged 23, engineer student at Sir Walter St. John's School, Battersea, 113 marks; Thomas W. Phillips, aged 23, student at British School, Millwall, and Royal College of Science, Dublin, 100 marks; Richard Sennett, aged 21, engineer student at the Royal School of Naval Architecture, 98 marks; Robert B. Buckley, aged 21, engineer student at Merchant Taylor's School, 97 marks; Charles E. Leeds, aged 23, B.A., (Oxon), student at Oxford University, 96 marks.

PRODUCING COLOURS FROM NAPHTHALINE.

SOME improvements in the production of colour from naphthaline have been made by Drs. Darmstadter and Wichelhan, of Berlin. The invention, which has been patented in England, consists in acting upon naphthaline with concentrated sulphuric acid, so as to obtain sulpho-naphthalic acid. Sulpho-naphthalic acid or salts of the same is then to be subjected to the action of an alkali, such as caustic soda or potash, at a high temperature, and from the resulting product, by the addition of an acid, such as sulphuric acid, naphthylic alcohol is obtained. The naphthylic alcohol obtained either by this or by other methods is submitted to the action of sulphuric and nitric acids, so as to transform it into dinitro-naphthylic alcohol, which product may be employed for the purposes of dyeing and printing.

About one part by weight of naphthaline is taken, and about one part by weight of concentrated sulphuric acid, and they are heated together at a temperature of about 100deg. Centigrade, until the greater proportion of the naphthaline has been converted into sulpho-naphthalic acid. This product is then to be dissolved in water, and the solution saturated with an alkali. The salts of sulpho-naphthalic acid thus obtained are evaporated to dryness, and are fused with an alkali, such as caustic potash or soda, or with mixtures of the same, so as to obtain compounds of naphthalic alcohol, which upon the addition of dilute acid to the aqueous solution the naphthylic alcohol or naphthol is precipitated and may be obtained in a crystalline form. The before-mentioned naphthylic alcohol or naphthol so prepared, or obtained from any other source, is to be dissolved in about an equal weight of strong sulphuric acid, and the solution is then gradually added to nitric acid diluted with water, the temperature of which mixture has been previously slightly elevated. The solution passes through different tints, but finally assumes a yellow colour, and the yellow colouring matter crystallises out of the solution on cooling. This substance has been called dinitro-naphthylic alcohol or dinitro-naphthol. The colouring matter thus obtained is to be freed from any adhering solution, and is then ready for use. Should it be necessary to subject the colouring matter to a process of purification it may be purified by solution in an alkali, ammonia for example, and be precipitated therefrom by means of muriate of ammonia or otherwise. When this colouring matter is to be employed for the purposes of dyeing or printing it may first be dissolved in a solvent, such as alcohol, or it may be dissolved in an alkaline solution. The pure substance, or its soluble salts, may either be employed alone or in conjunction with other colouring matters for the purposes of dyeing and printing.

PURIFYING AND BLEACHING OILS.

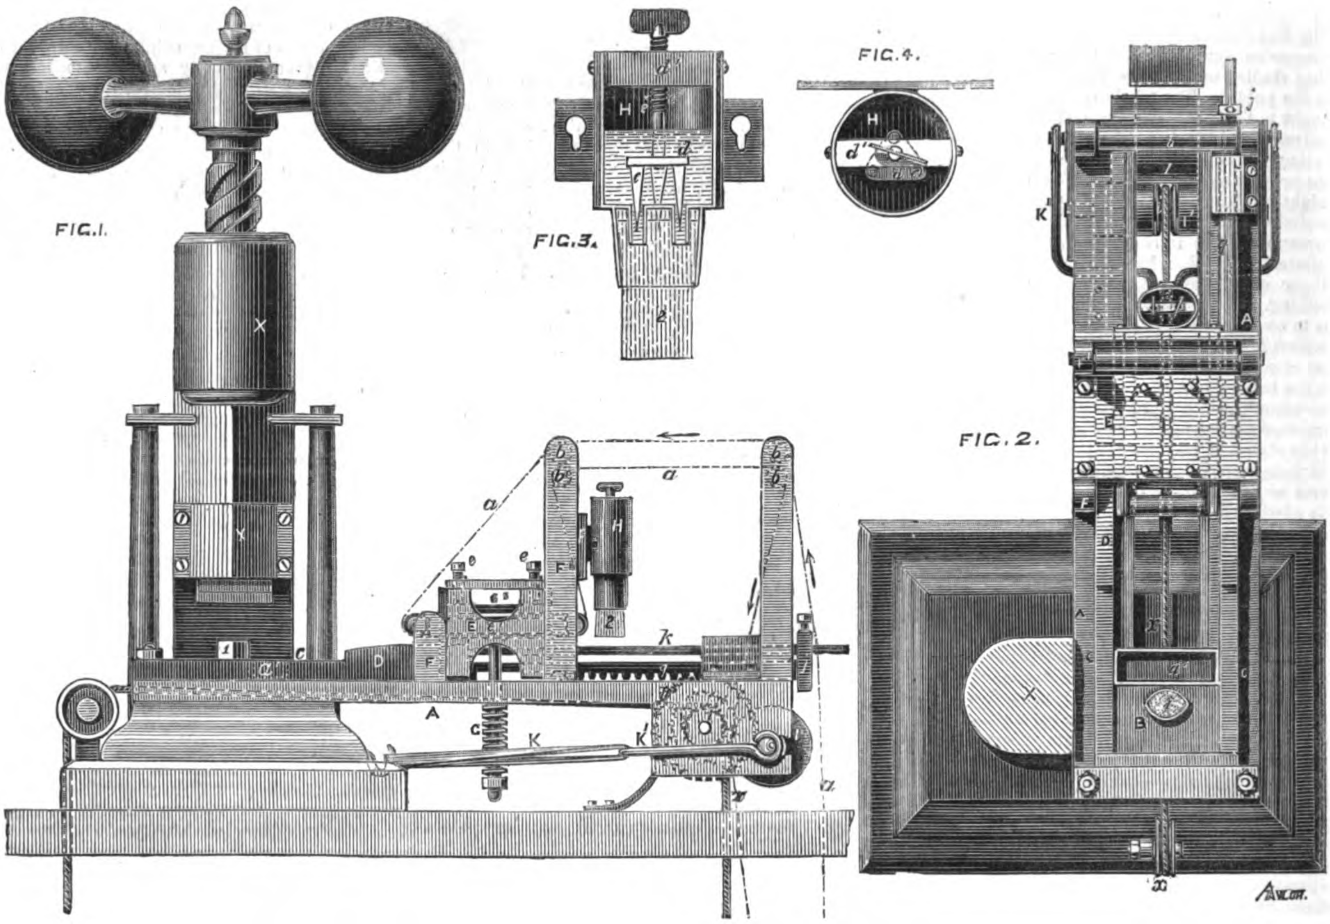
AN invention has been patented by Mr. W. Prosser, of Lancaster, Lecturer on Chemistry, and which consists in the purification, bleaching and saturation of animal and vegetable oils, also of gums and resins, as well as of such liquids as oi of turpentine, spirits of turpentine, and methylated spirits, by means of ozone, whereby much time is saved and greater purity obtained than by the methods at present in use. The substance to be acted upon, if liquid, as in the case of oils and spirits in their usual state, as well as the gums and resins in the melted state, is placed in a suitable vessel, and streams of ozonized atmospheric air or ozonized oxygen are forced through the substance. It is advisable to keep the liquid in motion so as to bring its particles in contact with the ozonized air or ozonized oxygen and thus expedite the process of ozonization, or the liquid substance may flow through a vessel possessing a large superficial area, and into which ozonized air or ozonized oxygen is passed. The great extent of surface permits the ozonized air to act readily upon the liquid and ozonize it. Or animal or vegetable charcoal in fine powder is saturated with ozonized air or ozonized oxygen, and the oils are exposed to the action of the ozonized charcoal. In the case of the gums or resins in their usual solid or unmelted state, Mr. Prosser exposes them in fine powder to the action of ozonized air or ozonized oxygen. By the continued action of ozonized air upon oil or spirits of turpentine, the latter becomes so saturated with ozone as to become vehicles for the conveyance of ozone to other substances. By ozonized air or ozonized oxygen is meant atmospheric air or oxygen ozonized by any artificial means.

VAULTS OF THE HOLBORN VIADUCT.

THE first occupation of vaults under the Holborn Viaduct has been made by Messrs. Fearon and Son, wine merchants, who have an extensive run of cellarage, as well as a large new building, adjoining their old premises in Holborn. The vaults open out of Shoe-lane, and run some 230ft. towards Hatton Garden, and are to have a tramway laid along them. They afford unusual facilities for loading and unloading, a wide passage running along the entrance, and affording sufficient room for waggons to draw up to the edge of each vault and unload without interfering with the ordinary traffic. The new establishment is very extensive and well constructed, with a view of being strong and fire-proof. The floors are supported on heavy girders carried on massive cast-iron columns. These premises are now being fitted up, and when completed, there will be four vats holding 1,100 gallons each, two of 4,000 gallons, about thirty of 800 gallons, and others of smaller holding capacity, to the total number of 140. In the basement will be a steam engine and boiler for pumping purposes and for working a lift, which communicates with every floor from the basement to the top rooms. The details are well carried out, and the arrangements will prove very perfect, every facility being afforded for carrying out the extensive business of this firm.

MACHINE FOR STAMPING AND EMBOSSING.

BY MR. J. PARKINS.



APPARATUS FOR STAMPING, EMBOSSING, OR PRINTING IN COLOURS.

THE object of the invention illustrated in the annexed engraving is to facilitate the operation of stamping, embossing, or printing in colours writing paper or envelopes. It has been patented by Mr. J. Parkins, of Brewer-street, Golden-square. Fig. 1 is an elevation, and fig. 2 a plan view of the machine; fig. 3 is a sectional elevation, and fig. 4 a plan view of the inking or colouring apparatus detached. A is an oblong metal frame fixed at one end to an ordinary stamping machine X and bevelled off on its inner edges so as to form V-guides on which the die bed B slides. This die bed consists of a steel or other metal block having a hole in it for the reception of the die 1. A small trough a^1 is attached to the inner side of the die bed to catch the superfluous ink that will be caused to flow round and down the die by the sharp edge of the die coming in contact with the brush 2 of the inking apparatus. Sliding on this oblong frame A is another and smaller metal frame C that receives a reciprocating or forward and backward motion from the die bed B, which is actuated by means of the cords *x z*, which are acted upon by a treadle and weight. On the sides of this second frame C are formed two vertical wedge-shaped cams D, which, as the frame C and die bed B are moved to the right in order to bring the die 1 under the inking brush 2, will support the cushion or impression frame E out of the way, so that the die 1 may pass forward without touching it. This frame E consists of two side pieces connected together at top by a cross plate, and sliding in upright standards F F^1, and carrying an india-rubber cushion.

The cushion e^1, which is shown by dots in fig. 1, consists of a small block of wood covered with india-rubber and fastened to a metal plate e^2. A band of paper *a* (shown in fig. 1) passes under the cushion, and when the die 1 returns to the press, the cushion presses down the paper *a* on to the die and thereby cleans it from the superfluous ink. The block of wood is formed with a corrugated surface in order that the edges of the die may be properly cleaned. The requisite amount of pressure is given to this cushion frame by means of rods G tapped at their lower ends and projecting from its under side through the oblong frame A, and descending a sufficient depth to allow of a helical spring being adapted to them, the tension of which is regulated by a screw nut. The elastic cushion is made adjustable, so that when a larger or smaller die is used, the cushion may be raised or lowered. This will be done by means of screws *e e* working through the top plate of the cushion frame E, and fastened to the metal plate e^2 of the cushion. The inking apparatus is attached to an adjustable cross piece *f* fixed to the upright guides F^1 of the cushion frame. These uprights F^1 also carry rollers *b* b^1 to facilitate the onward intermittent motion of the die-cleaning paper band *a*.

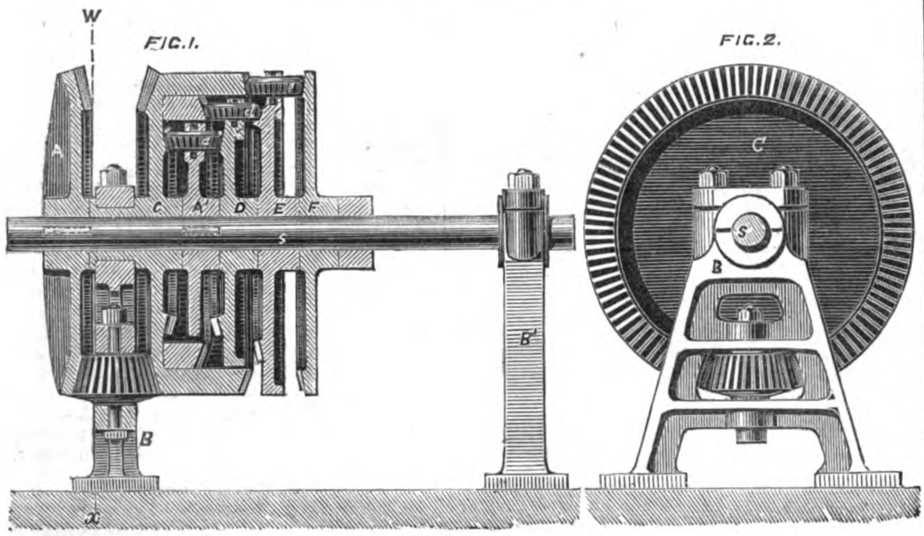
The inking apparatus, which is shown detached and drawn upon an enlarged scale at figs. 3 and 4, consists of a reservoir or cylinder H for holding the ink. To the lower end of this cylinder a brush 2 is attached; in the bottom of this reservoir or cylinder H are holes, the number varying according to the dimensions of the brush. Or a slot may be cut across the bottom of the cylinder or reservoir H, and, by means of short tubes, the ink will flow down into the brush. In order to regulate the flow of ink into the brush, small conical pins or V pieces *c c* fixed to a plate *d* are inserted into the mouth of these holes, and are raised or lowered therein by means of a vertical screw e^* connected to the plate *d*, and working through a cross piece d^1 fitted to the upper end of the reservoir or cylinder, so that by merely turning the screw e^* a larger or smaller quantity of ink may be allowed to pass into the brush as required.

In order to properly actuate the die-cleaning paper band *a*, and impart an intermittent progressive motion thereto, so that the die should not press against it twice in the same place, two nipping rollers I I^1 are employed, between which the band *a* passes in the direction of the arrows. These rollers are covered with vulcanised india-rubber, and are actuated by a rack *g* and pinion *h*, the latter being mounted on the shaft *i* of the nipping roller I^1. A click and ratchet is adapted to the axle or shaft *i*, the whole being actuated by the reciprocating sliding frame C. The length of stroke of this rack and pinion is regulated by means of an adjustable tappet or block *j* on a rod *k* attached to and extending from the sliding frame C. The nipping roller I^1 is composed of two small rollers mounted on the same shaft *i* and working together and having between them a small pulley *l*, fig. 2, running loosely on the shaft to act as a guide for the treadle cord X. In order to keep the nipping rollers I I^1 at proper tension and in position, there is an elastic band K and stretcher K^1 provided with hooked ends, whereby it is attached to the ends of the shaft of the roller I. Scrapers or doctors are adapted to some of the rollers to keep them clean and prevent the inked paper from sticking to them. In order to prevent the nipping rollers from rotating in the wrong direction, there are on the shaft *i*, and at the opposite end of the roller I^1, a ratchet wheel and spring.

The mode of operating the machine is as follows:—Upon pressure being applied from the treadle to the cord *x*, the bed plate B is drawn forward or to the right until it strikes against the rear end of the sliding frame C; it then continues its forward motion with the sliding frame C until it is clear of the inking or colour brush 2. At the same time that the die passes under the cushion frame E, the elastic cushion e^1 will be held up by the wedge-shaped cams D, but as the frame C will be moved forward with the die bed B it will be evident that as soon as the die 1 arrives under the brush 2, the cushion frame e^1 will fall. On the pressure being removed from the treadle cord *x*, the die bed B will be drawn back, that is, to the left, to the front end of the frame C by the weighted cord *z*, to and will thus pass under the elastic cushion e^1 to the stamping press. But as the elastic cushion e^1 will not then be held up by the cams D, the die 1 will press against the paper band *a*, and the superfluous ink will be thereby wiped off therefrom. The sliding frame C will continue to be drawn back by the die bed B until the cams D again come into operation and raise the cushion frame E out of the way of the die ready for the next inking operation. The paper band *a* (which is wound on a drum fixed under the table) passes over the rollers *b* in the direction of the arrows and under the elastic cushion E, as shown in dotted lines, and from thence over the rollers b^1 to the nipping rollers I I^1. The clean die with its proper supply of ink having been brought under the stamping press, the paper is placed thereon and the impression given in the ordinary way.

MULTIPLYING GEARING.

BY MR. L. S. FITHIAN.



GEARING FOR MULTIPLYING MOTION ON A SINGLE SHAFT.

THE invention we are about to describe relates to a new and useful combination and arrangement of cog wheels on a single horizontal shaft, whereby motion may be increased, and thereby greatly simplifying the methods in common use for that purpose. It is the invention of Mr. L. S. Fithian of Brooklyn, U.S. In our engraving fig. 1 is a longitudinal vertical section of the arrangement; fig. 2 is a sectional elevation taken in the line W X, fig. 1. The shaft S S is supported on the standards B B [1], and carries the bevel wheel or disc A, which is keyed thereto. The standard B has a slot to receive the pinion *b* to connect the wheels A and C. The wheel or disc C is cogged on both sides and revolves loosely on the shaft. A lever or disc A [1] is made fast on the shaft S and carries a pinion *a*, which gears into the wheel C and also into a similar wheel D, which also drives two similar wheels E and F. All these wheels or discs are provided with slotted lugs to receive pinions for transmitting motion from one to the other. The wheels E and F are allowed to revolve on the shaft S S.

The manner of working this arrangement of parts is as follows:—The revolution of the wheel A will, through the pinion *b*, act upon the wheel C, giving the latter a corresponding motion in the reverse direction, and the bevel wheel A being fast on the shaft will at the same time revolve the shaft and the lever A [1] with it, and by means of the pinion *a* will receive motion from the wheel C and transmit the motion to the wheel D, which, also carrying a pinion *d*, acts on the wheel or disc E, which thus receives motion from C. The wheel or disc E carries a pinion *e*, which also receives motion from the wheel or disc C and transmits it to F, and so on indefinitely as wheels are added. The number of revolutions each wheel will make will be as follows:—The wheel D three, the wheel E seven, and the wheel F fifteen revolutions in the same time that the wheel A makes one. If it be desired to multiply the reverse motion it may be done by means of multiplying wheels in the slot B, or the inertia motion may be increased by multiplying wheels in the slots in the wheels A [1] D E. In place of the wheel C an increased series of bevelled cogs, or the section of a sphere with a series of cogs upon it, or a cylinder or shaft cogged upon the outer side, may be employed with corresponding levers and discs taking motion from the bevels, spheres, or cylinder shaft, and continue the same motion or increasing leverage and decreasing motion as communication is made with pinions placed horizontally to the shaft, or with an increasing angle up to the vertical and thus passing on to a longer lever instead of a shorter.

PROFESSOR AGASSIZ says that fish is a kind of food which refreshes the system, especially after intellectual fatigue. There is no other article that supplies the waste of the head so thoroughly as fish diet. Fish contains phosphorus to a large extent—a chemical element which the brain requires for growth and health.

METEOROLOGICAL EXPERIMENTS IN THE CAPTIVE BALLOON.*

BY MR. J. GLAISHER.

THE report of the results of the meteorological experiments made with the Captive balloon by Mr. Glaisher is a most important contribution to science, helping to fill, as it does, a long-felt hiatus in his most valuable and instructive series of meteorological observations. The main points of his report may be thus stated:—The necessity which existed in all his previous balloon ascents of leaving the earth with a great ascending power to avoid striking adjacent buildings, caused the first few hundred feet to be passed through too quickly to determine satisfactorily the states of temperature and humidity of the air at the low elevations; at the higher they could be repeated at will, descending by opening the valve, and ascending by the discharge of gas; but this could not be done near the surface of the earth, and, consequently, a certain amount of doubt has rested upon all the observations thus taken, and our knowledge of the distribution of heat and humidity up to 1,000ft. high has, therefore, been very limited indeed. The theory of a decline of 1deg. of temperature in the increase of every 300 of elevation was evidently erroneous, such not being confirmed in a single experiment. In some of the ascents, a decline as large as 2¼deg. was observed in the first 100ft., and there is every probability that, if on these days the balloon could have been kept stationary for some time so as to have made certain that the true temperature at the 100ft. had been attained, it would have been as large as 3deg., while, on other occasions, no change of temperature has been experienced while passing through several hundred feet of elevation. Thus, on some occasions, at 1,000ft. high, a temperature 10deg. less than on the ground has been recorded, whilst, in others, no difference was found within the distance of 1,000ft. from the earth. Thus, the observations near the earth made by means of a free balloon proved that the decline of temperature with increase of elevation varied greatly. It was distinctly found to be different, depending on the clear or cloudy state of the sky, but there were indications that it was different at the different times of the day. This indication was partly confirmed by an accidental descending of the balloon at about sunset, when scarcely any change of temperature was experienced within half a mile of the earth, and, consequently, it seemed possible that, if balloon ascents could be made at night, then the temperature might increase and not decrease from the earth to some distance from the earth, and this inference was proved to be correct so far as ascertained by the only two night ascents made by Mr. Glaisher, for, in both of them, a higher temperature was met with on leaving the earth. Thus, the results of the several balloon ascents were to unsettle our previous views and to cause a suspicion to rest on the laws of refraction, but the appointments were too few in number, and particularly at night, to speak with any confidence.

The great Captive balloon, with its powerful and beautiful machinery, recently located at Ashburnham Park, was well adapted to settle all these points, and Mr. Giffard, its proprietor, placed it at Mr. Glaisher's disposal for any series of experiments to which he could apply it. This balloon could ascend on a calm day to the height of 2,000ft., and he had made about thirty sets of experiments. Each set consisted of readings of Fahrenheit for the determining of the temperature and humidity of the atmosphere at every 100ft. of elevation, with full power of being stationary at any point. Usually, the ascent and descent were slow and regular, remaining always at the extreme point a sufficient length of time to ensure the true states at the elevation, and then the descent was made, slowly and regularly as the ascent; the mean of the readings at the different elevations, ascending and descending, and the mean, on the ground before and after the ascent, have been considered.

Without entering into many details, Mr. Glaisher briefly stated the general results, which are—that with a clear sky, the decline of temperature with elevation is the greatest during the mid-day hours, amounting to 5·10deg. in the 1,000ft., and becomes less and less as the day advances till, at about the time of sunset, there is little or no difference, and that the decline is greatest nearest to the earth, amounting in the first 100ft. to more than 1deg., and from 900ft. to 1,000ft. to about half a degree less. In the cloudy state of the sky, the decline in the day hours is a little smaller than with a clear sky, the larger decrease being nearer, but, as the day advances, the decrease at or about the time of sunset is about 0·5deg. for every 100ft. up to 1,000ft. high. These results prove that the rate of decrease of temperature with elevation varies with the time of the day, confirming that which the free balloon ascents indicated, and giving to them an increased value.

It is to be regretted that, both for the want of time and arrangements, he had made no ascent after sunset, which is now the most important inquiry we have, to determine, if possible, the laws appertaining to the night hours, and bearing directly upon the law of refraction, during the period when the greatest number of astronomical observations were made; and he hoped, if this great balloon were used again, it would be in a more convenient locality, and that each set of observations would not exact so much time. As examples of the variations of temperature at the lower levels, we may give the following, taken under a clear sky:—At three o'clock, temperature at ground, 76·2deg.; at seven o'clock, 70·9deg. At 1,000ft., at three o'clock, 68·9deg.; at seven o'clock, 67·9deg. Thus, while there was a decrease of temperature on the earth of 5·3deg. from three to seven o'clock on the ground, the decrease at the height of 1,000ft. was 0·9deg. only; and, at half-past seven, the following variations were observed:—At the ground, 70·9deg.; at 100ft., 70·9deg.; at 200ft., 70·8deg.; at 300ft., 70·5deg.; at 100ft., 70·2deg.; and at 400ft., 69·8deg.

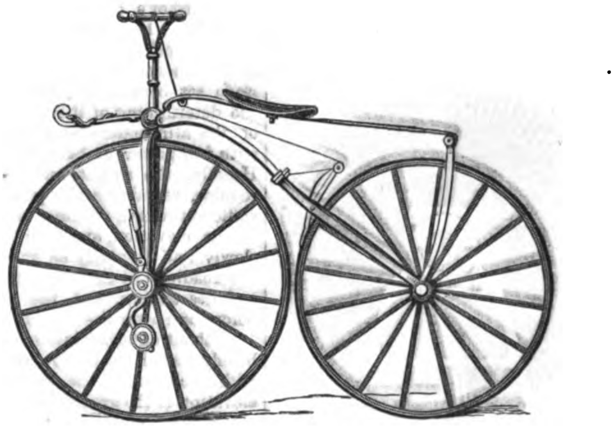
A NEW VELOCIPEDE ACTION.

WHEN it is considered that one-fourth only of the revolution of a crank is available for exercising useful pressure for producing rotation, it is somewhat surprising that velocipedes have until now, been constructed so as to cause a great waste of power to the rider. The feet have to travel completely round the axle in following the cranks; hence an enormous sacrifice of time and useful power. With the object of saving this great waste, and providing an efficient substitute for the ordinary cranks, the invention we illustrate has been designed and patented by Mr. J. G. Wilson, engineer, of Market-place, Manchester. It was exhibited for the first time in public at the recent meeting of the Royal Agricultural Show at Manchester, where it excited the interest of all who were puzzled to know how a revolving motion could be produced by simpfy oscillating the feet and without the assistance ol toothed or ratchet wheel-work. The principal feature of difference between this arrangement and the crank is that when the necessary speed is attained the feet may rest upon the treadles without working or even moving a muscle, whereas with the crank they must either be removed altogether or go round the axle.

Our engraving represents the motion applied to an ordinary bicycle, and the details are illustrated on an enlarged scale in figs. 1 and 2, the former showing a front view, and the latter a side view of the new driving mechanism. A is the axle or driving-shaft of the velocipede, upon which

* British Association.

A NEW VELOCIPEDE ACTION.



is keyed a disc-wheel B, which has a perfectly smooth periphery. Two radial arms or links C C work upon the axle A, on either side of the disc-wheel B, one of such arms or links being extended downwards, and there having a counterbalancing weight D affixed. E is the actuating lever mounted upon a pin between the upper extremities of the radial arms or links C C, the shorter arm of which lever impinges upon the periphery of the disc-wheel B immediately upon pressure being applied to the foot-plate F, which is situated at the extremity of its longer arm.

The action of this driving mechanism may be thus described:—When the actuating lever E is in a vertical position, the foot is placed upon the foot-plate F, and pressure being applied to it, the short arm of the actuating lever E binds upon the disc-wheel B, and as it cannot pass the axle A is thereby caused to turn in its bearings in the same direction as the pressure is applied. The foot having advanced through a quarter of a circle or revolution, viz., from a vertical to a horizontal position, is now drawn back again to the starting point, assisted by the action of the weight D, leaving the axle meanwhile free to revolve, when by re-applying pressure in the same direction another grip of the disc-wheel may be taken whilst it is still revolving, and thus, by oscillating the actuating lever E backwards and forwards a continuous

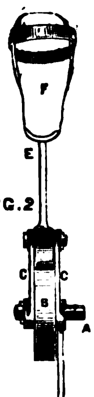


FIG.2

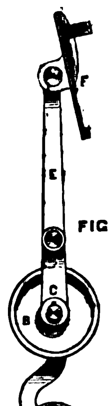

FIG.1

revolving motion may be communicated to the driving wheel in the same manner as drilling with a ratchet brace, with this difference, that in this arrangement there are no teeth nor serrations formed on the disc-wheel, and, instead of being intermittent, the motion is continuous, and any desired speed may be attained.

With Mr. Wilson's invention it becomes practicable for a rider of ordinary stature to use any size of driving wheels, an advantage which cannot be over estimated when viewed in the light of competing in velocipede contests. The same speed can be obtained by this driving mechanism as with the ordinary cranks, whilst at the same time the motion is considerably easier and less fatiguing in consequence of the actuating foot levers or treadles being much longer than any crank that could be applied to the purpose. For rough roads or for hilly country this motion is peculiarly applicable, as the power which can be brought continuously to bear is sufficient to overcome any impediment, or to ascend any gradient.

FETTLING OR LINING PUDDLING FURNACES.

In the ordinary method of fettling or lining the beds and sides of puddling furnaces oxide of iron or a compound consisting mainly of oxide of iron is employed for that purpose. An invention patented by Mr. W. M. Williams, of Sheffield, consists in lining puddling furnaces with crude or prepared oxide of manganese or manganese ore either as the chief ingredient of the fettling or as an addition to the oxide of iron or other material, which is employed. In using crude or native oxide of manganese or manganese ore without admixture with other solid, an ore is used which when pulverised and moistened will form a plastic or pasty mass, and which when heated will harden and adhere firmly to the sides and bottom of the puddling furnace. For this purpose the cheap oxides containing a considerable proportion of iron are best suited, provided they do not also contain other impurities, such as sulphur and phosphorus, which would injure the iron in the furnace. When an ore or prepared oxide is used which does not harden sufficiently, after being rendered plastic by water alone, it is mixed with a sufficient quantity of finely powdered and moistened hæmatite or other suitable material to give it the property of hardening and adhering when heated in the furnace.

The proportions in which oxide of manganese and oxide of iron should be mixed in order to make the fettling according to this invention vary with the nature of the cast or pig iron to be puddled. With pig iron of ordinary quality about half a hundredweight of oxide of manganese mixed with the requisite quantity of oxide of iron for the fettling of the furnace is sufficient for a charge of four to five hundredweight of pig iron. When the pig iron itself is rich in manganese a less proportion is necessary in the fettling. When the pig iron contains a large quantity of silicon and little manganese more oxid of manganese is required in the fettling than is required with pig iron containing much oxide of manganese and little silicon. Where practicable the inventor prefers to introduce the pig iron into the puddling furnace in a melted state; when this is done and the fettling containing oxide of manganese is laid on the bottom and lower part of the sides of the furnace the charge gets the full benefit of the evolution of oxygen, which takes place when the oxide of manganese is heated. By the use of oxide of manganese, as described, the puddling process is expedited, and the quality of the iron or steel produced is improved. The heated iron or steel during the puddling process decomposes the oxide of manganese, causing an evolution of oxygen, which rising through the molten iron or steel rapidly oxidizes the oxidizable materials contained in the metal. A portion of the reduced manganese enters into alloy with the iron or steel and effects the improvement in the quality of the metal which is well known to result from the use of manganese in the manufacture of iron or steel.

When oxide of manganese is mixed directly with the charge for fluxing, as has been proposed, a portion is liable to become mechanically distributed through the mass of iron or steel in the state of an infusible powder, consisting of manganese in a low state of oxidation, and injures the mechanical properties of the metal. But when oxide of manganese is used in the fettling of the puddling furnace according to this invention it is gradually decomposed as the carbon and silicon of the pig iron or steel are presented to it by the stirring of the puddler, and the manganese enters the charge in a fused state either as reduced metal or as silicate.

Very little of the manganese which enters the iron or steel during the puddling process remains in the finished metal, most of the manganese separating during the finishing of the metal in the form of silicate of manganese, carrying with it other impurities, such as phosphorus and sulphur. The silicate of manganese separates from the metal more readily than silicate of iron, and is found in considerable quantity in the cinder and hammer slag. The cinder and hammer slag are therefore more valuable than ordinary cinder or hammer slag for the making of cinder iron in consequence of their richness in manganese. Although the fluxing property of oxide of manganese, either alone or mixed with oxide of iron, renders the addition of any other material to the fettling unnecessary when pig iron or steel of the ordinary qualities are puddled, yet when pig iron or steel of such quality as renders the use of alkaline fluxes desirable is about to be puddled, common salt or carbonate or nitrate of soda may be added to the oxide of manganese. A quantity of the soda salt equal to about one-fourth the weight of the oxide of manganese is generally sufficient.

OVERHEATING OF FURNACE CROWNS AND OTHER BOILER PLATES WHEN COVERED WITH WATER.

By Mr. L. E. Fletcher.

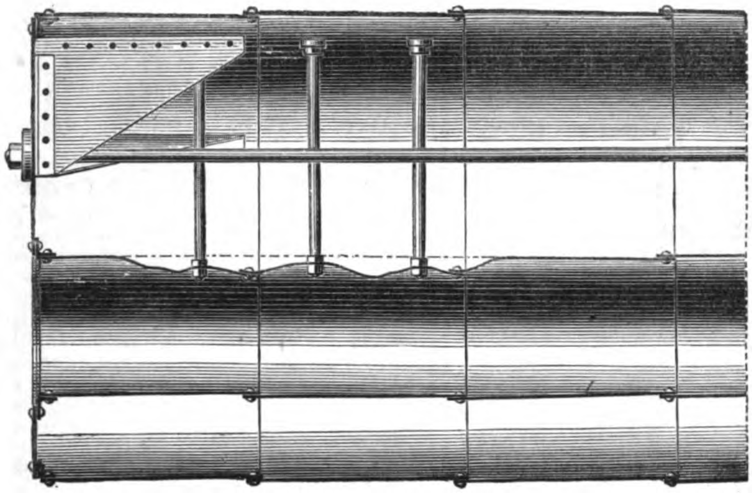
Everyone at all conversant with the working of boilers is aware that when they are allowed to run short of water the furnace crowns are apt to become overheated, the plates to be bulged downwards or otherwise distorted by the pressure of the steam, and in many cases to be rent, from which cause explosions frequently arise. This is admitted on all hands, and the rationale is so simple that the whole must be at once apparent. It is not however by any means so generally known that furnace crowns may be overheated and bulged out of shape—sufficiently so in some cases to cause an explosion—even when they are covered with an ample supply of water. Such, however, is unquestionably the fact, and I wish specially to call attention to this subject on the present occasion.

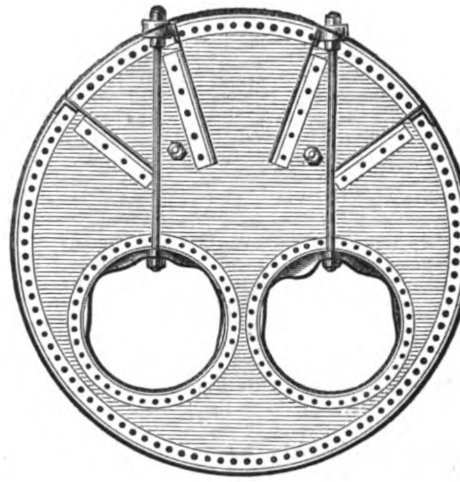
Overheating of boiler plates when covered with water has been found to arise from two causes, one, the too local action of an intense fire, the other the character of the feed water. Injury from intense firing sometimes occurs to boilers heated by the flames passing off from separate furnaces constructed of firebrick, as in the case of puddling furnaces at ironworks, when the flames are too frequently allowed to impinge directly upon the boiler, in consequence of which steam is generated so rapidly that the water is driven off from the plates, and overheating ensues. This is more especially the case where the heating surface is a vertical one, so that the steam on rising forms a separating film between it and the water. Two explosions resulting from this cause may be referred to. One of these occurred at an ironworks on February 9, 1865, to an externally-fired boiler, of the upright furnace class, heated by the flames passing off from two puddling furnaces, as well as from a large firegrate. Another explosion of a similar character occurred on February 7, 1866, to a plain cylindrical egg-ended boiler, heated by the flames passing off from a mill furnace at a works employed in the manufacture of angle iron.

It is desired, however, on the present occasion to call attention more especially to those cases in which overheating of the plates, whether in externally or internally-fired boilers, has occurred simply through the character of the feed water, and not from any peculiarity in the mode of firing. The feed water, which is found to be more particularly productive of overheating, is highly impregnated with carbonate of lime. It forms but little scale, and that seldom thicker than an egg shell, though perhaps in some cases it may be nearly equal to one-eighth of an inch. It deposits, however, a good deal of fine flour or dust, which is generally of a lightish colour. As this dust is quite loose, a good deal of it is floated away with the water when the boiler is emptied, while the remainder is readily washed out, so that on account of the ease with which it is removed, and the light character of the scale, it frequently escapes attention. If grease be introduced into boilers in which this deposit is formed, the furnace crowns are found to give way, the plates to bulge downwards, and leakage to take place at the seams of rivets. The distortion of the furnace plates, however, does not, as a rule, take place suddenly; on the contrary, the crowns come down very gradually, progressing little by little day after day, though hard firing in many cases has an immediate influence. Grease is introduced into boilers in various ways. The feed water is frequently heated by blowing the exhaust steam from the engines upon it, so that the grease in the cylinders is carried with

OVERHEATING OF FURNACE CROWNS AND BOILER PLATES.

BY. MR. L. E. FLETCHER.





the feed water into the boiler, while in addition, the discharge taps from the cylinders sometimes blow into the cistern from which the feed pump draws, so that the boiler gets all the engine sewage. Blowing the exhaust steam upon the feed water has another effect beside the introduction of grease. It is sometimes lost sight of how much of the deposit formed within boilers is lifted out of the water by the steam and carried through to the engines, and thus disposed of either through the exhaust pipe in high-pressure engines or in the hot well in low-pressure ones. When therefore the exhaust is blown upon the feed water this deposit is returned to the boilers, and a constant accumulation takes place, more especially if blowing out be neglected. That the steam lifts the deposit and carries it along with it is clear from the fact that it is frequently manifested at the glands and other parts of the engines, and also is heaped up in the steam dome when there is a shelf on which it can accumulate. These shelves are formed when the shell plate at the base of the dome is not cut away to its full size. This forms an eddy in the current of the steam, and leads to the deposit being dropped on the shelf plate as just stated.

With regard to the manner in which this floury deposit affects the plates over the fire, and leads to their injury, it does not appear to be necessary to suppose that this deposit becomes heaped upon the plates in order to lead to their overheating. It is doubtful whether it settles at all as long as the boiler remains in active work; while, were it to do so, it would settle where the ebullition was the least violent, and thus not on the furnace crowns of internally-fired boilers. Possibly, this fine floury deposit, by thickening the water, interferes with the due escape of the globules of steam, so that they are kept longer in contact with the plates over the fire than they should be, and thus the intimate contact of the water with the plates becomes interrupted and overheating is produced. This may, perhaps, be illustrated in the following way:—Clear water placed in a clean saucepan may be briskly boiled over a fire without foaming over, but if a little meal be dropped into it, or the water exchanged for milk, the globules of steam are no longer able to escape freely, and in their struggle they upheave the whole mass, and vomit a portion of it into the fire. Such is thought to be somewhat the action that takes place within a boiler charged with this fine floury deposit. The globules of steam, imprisoned in the water, lift it from the plates in their struggle to escape, and thus gradual overheating takes place in proportion to the character of the water and the intensity of the fire.

I am not desirous, however, of entering too minutely upon the precise manner in which this floury deposit leads to the overheating of the plates: suffice it to say, that the results are indisputable, that numbers of boilers have been injured by it, and whatever may be the precise *modus operandi*, it appears to have the power of preventing that intimate contact of the water with the plates which is essential for carrying off the heat with sufficient rapidity, so that, although they may not be made red hot, yet they become sufficiently overheated to lose a portion of their tenacity, when bulging under pressure ensues. Numerous instances of this have come before my notice, the particulars of some of which may now be given.

The first of the cases that may be referred to was met with about the close of 1862, and occurred to a boiler fed from a well sunk near the river Mersey, in the neighbourhood of Birkenhead. The boiler was of the ordinary Lancashire class, having two furnace tubes in which the fires were placed, while its length was about 20ft., its diameter 6ft. 6in. in the shell, 1ft. 10½in. in the furnace tubes, and the load upon the safety-valve 40lb. per square inch. This boiler had been found to give way again and again at the furnace crowns, the plates bulging down out of shape, and repeated repairs had taken place in consequence. The plates over the fires had been taken out and renewed with those of Low Moor iron, which had every appearance of being of first-rate quality. Also each of the furnace crowns had been lashed to the top of the shell by three vertical stay rods, but the plates persisted in bulging downwards notwithstanding, and came down between, and all round, the points of support, as will be seen on consulting the accompanying cuts.

Under these circumstances I was requested to examine the boiler and advise the owners as to what had better be done. Immediately on drawing off a little water from the glass water gauge I attributed the injury that had occurred to the furnace crowns to the fine deposit contained in the feed water, and recommended a scum trough for blowing out from the surface of the water, in order to rid the boiler of this deposit. In answer to inquiries the owners did not think they were admitting any grease to the boiler, and had such confidence in the feed water, which appeared so clear before it was pumped into the boiler, that I was unable to persuade them to adopt the simple expedient of a surface blow-out apparatus. One cause after another was assigned for the injury, and it was supposed that, as the boiler was worked night and day, the water supply had been allowed to run short at night time, and that the deflection of the plates was due to a series of minor neglects of this character. On one occasion the owners felt sure they had at last detected the source of the mischief. They discovered that the fireman, anxious to get away quickly on the Saturday evening, had started to blow off his boiler before he raked out the fires, in consequence of which the furnace crowns were laid bare with the fires still in, and thus became overheated. In confirmation of this it was stated that it had been frequently observed on setting to work on Monday mornings that these deflections had been increased, so that the chain of evidence was supposed to be complete. It was soon found, however, that the bulging was too persistent to be accounted for in this way, and the owners, rather than adopt the simple expedient of putting in a scum trough for blowing out the deposit, which there is little doubt would have remedied the evil, resolved on condemning the boiler altogether and on putting in a new one.

The new boiler was of larger dimensions than the old one, the diameter being 7ft. in the shell, instead of 6ft. 6in., and 2ft. 7½in. in the furnace tubes, instead of 1ft. 10½in., while the tubes were strengthened at the ring seams of rivets with encircling hoops, which had not been the case in the old boiler. With this new boiler, though not fitted with a surface blow-out apparatus, the same difficulty was not experienced as with the old one, which arose from the fact that the superior size of the new boiler enabled it to do its work more easily than the others, and thus with more gentle firing. As long, however, as the feed is of the same character as it was in the other boiler, the same tendency remains, and it will only be necessary to make the new boiler do as much work for its size as the old one did to lead to the furnace crowns being again disturbed, though doubtless they would derive considerable assistance from the encircling hoops, so that but little bulging of the plates might take place, though leakage would occur at the seams of rivets. In this case the water was not analysed, as it was on subsequent occasions, but it may be stated that it left a fine floury deposit of a very similar character to other cases mentioned, and which were found to consist of from 70 to 80 per cent. of carbonate of lime.

(To be continued.)

Correspondence.

THE ROYAL AGRICULTURAL SHOW AND THE PLOUGH: ITS HISTORY AND ACTION UPON THE SOIL BOTH IN ANCIENT AND MODERN TIMES, AND THE MODIFICATIONS IT HAS UNDERGONE.

LETTER No. I.

TO THE EDITOR OF THE "MECHANICS' MAGAZINE."

SIR,—Some of our most useful agricultural implements are lost to the farmer by the want of a better mechanical education among our farm labourers, and we hail with satisfaction the interest and large space devoted to the Royal Agricultural Show in a high-class scientific paper like the MECHANICS' MAGAZINE. It is almost the only means which can mould the minds of the farmer and his men to the ready and willing adoption of those changes which from time to time must come if the British farmer is to hold his own against the rapidly-increasing foreign competition under free trade. Indeed, a greater interchange of ideas must take place between the minds of scientific men and our artisans and labourers if England is to maintain its high position among nations.

Civilisation advances in proportion to the rapid and constant communication one section of society holds with another. In the early history of England, the dwellers on the sea coast, from this cause, were more intelligent than those living in the interior; but now this difference no longer exists, for, whilst the seashore boasts of its shipping, our inlands are justly proud of their hives of intelligent industry, which, together with railways, penny post, and newspapers sent to the most remote hamlets, give the dwellers of the country as broad a path for the attainment of high-class knowledge as the denizens of the city. And in this state it might be supposed man could be left. But the pioneers of human progress think otherwise, and wish for the nations of the earth to bring to one centre their handiworks, that men might compare the works of genius of other lands by the side of their own. And how completely has this been borne out by the late Royal Agricultural Show at Manchester, which has drawn thousands of people together daily for fourteen days to inspect the grand array of the mechanical sciences: and who could go there and not come away a wiser and a better person? The proud and haughty would see that there were greater souls than their own in existence. To the doubting and sorrowful, there was something hopeful.

It is not with the general mass of things which were exhibited at the Royal Show that we are about to treat, but with one article only, and that article is the plough. The word is not very imposing, nor is it very winning in its appearance, yet

this little implement plays one of the most important parts in the political economy of nations. Mankind at large are not aware of the silent yet all-important part that agriculture plays in this modern world of £ s. d. We read of the great manufacturing interests, of our mighty shipping interests, of the £30,000,000 worth of cotton that annually comes from America, of the iron, mine, and coal interests; and we forget, or we do not know, what comes every year from our green pastures and the rich valleys teeming with fat oxen, and the yellow patches and the long lines of red which tell of the rich and golden harvest we are now reaping for our winter's store—a store of which the wheat alone is worth upwards of £60,000,000 sterling. And then add to this the value of the beans, oats, barley, turnips, and we shall have a sum total that far exceeds any other interest in the world; and, when we consider that all this value is produced by the plough, we shall see at once the importance of the implement.

The plough was never shown to more advantage or greater contrast at any previous Royal Show. The steam plough is one of the grand epochs in modern civilisation. It is to find more food for man. It is to give man the land—the broad acres that are now wanted to feed the horses that are required in farming. A more noble idea could not be started; yet it is, like many others of its class, a long way off its completion. But this difficulty will give way to more useful and better implements in steam tillage. Up to this time, steam has done no more than bring the old horse implements, made larger, to bear upon the soil, and worked, not by the force of any new intelligence, but by the more than brute strength of the steam boiler. The steam plough ought to do for the land what the spinning jenny has done for cotton. The number of operations now required for high-class cultivation by the implements in use make farming expensive and tedious. The implement that cultivates the soil, whether by horse or steam, should, upon all clean land, make a good seed bed at one operation, and then we might say that we have an intelligence as great on the farm as makes the arts and the sciences.

The first labour imposed upon man was to till ground. Thus, agriculture is the first institution on the face of the earth, and it must last when all others have passed away, for it is the only means of sustaining existence. The whole animal and vegetable creation die, rocks moulder away, and seas may be swallowed up, but the fertility of the soil is as perfect now as it was when man was first sent forth to till it.

What the first implement was that man tilled the ground with we may never know, but the first implement we find in his hand is the hoe, and that almost in the same form as the one now in use, and from this hoe the plough springs. But many hundreds of years may have rolled on before this change took place. The Egyptians were the first great fathers of agriculture, and their plough had the same form in its cutting edge as the one now in use, except that the share was on the left side, which is not to be found on any other plough in the world. So much did the Pharaohs reverence the plough above all other things that it was the only ornament in the crown of the "mighty Pharaohs," kings of Egypt, and the Egyptians in those days held the granaries of the known world. Rude as the Pharaoh plough was, it was the first grand attempt at that implement, and it was capable of breaking up every part of a field as perfectly as any of our best ploughs with the turn-furrow off. All other ploughs of this period, and for centuries after, acted equally on each side of the beam, which would prevent them from breaking up a field regularly and with facility. As the side broken up would be softer than the land not acted upon, the plough would be forced from the hard soil to the soft, and miss the land.

It is wonderful how little we have altered the share of our ploughs and cultivators for many thousands of years. It is the body and handles of the implement that have undergone the greatest change, and not the cutting line of the share. It is an old saying that there is nothing new under the sun, for the supposed model Woolstontine is just in the form of the earliest ploughs, a chisel-shaped edge about 4in. broad, with a long and gentle incline rising up to the frame. If the chisel-shaped share be objected to, the Chinese, many thousand years ago, had a duck's foot or diamond-shaped share to their plough, and a long incline for the earth to rise up after it is cut that it might be well broken before it left the plough. The present Kent turn-rise plough is just in the form of the old Chinese plough if the turn-furrow was taken off. All who visited the Royal Show at Canterbury must have been struck with the truly antediluvian appearance of the turn-rise plough. Old as this implement is—for it dates from the earliest period,—the "men of Kent" will not give it up; yet it takes a horse more draught than the fashionable iron plough, for there is a raging fashion in ploughs as well as in ladies' bonnets from time to time, which has long stood in the way of real progress. The Kent plough leaves no hollow in the furrow, and breaks the slice up much more than the solid cut of the common plough.

The ancient Romans worked one of the most awkward-looking ploughs, the handle perpendicular to the cutting edge, and the draught beam forming the hypothenuse line. The ancient Greeks are supposed to be the first to have used a share all solid iron. Russia was the first to use iron coulters, but they were round, and evidently used for rising and falling, the cutting edge of the share being attached to it, as they were the first to alter the pitch of the share. This was a great stride. The Circassians or Georgians were the first to use iron coulters detached from the share, which, strange to say, is in the most approved form of those in use at the present day. Switzerland comes next with not quite so perfect a plough. In all the ploughs of the ancients there were no turn-furrows, but the next period following that there were some attempts. The rudest attempt at the turn-furrow is by the Spaniards, consisting of two short bits of wood at right angles at the back of the plough. The Chinese plough, which is the best of all the ancients'—except the Pharaoh,—had two bits of wood placed at an angle of 45 to the cut, which, as a matter of course, must move the earth more or less at one side, but acted on each side alike. Austria, France, and Italy had the same sort of bars on each side, but their ploughs were not such useful implements. The Normans had two iron wings, one on each side, but their ends were bent completely forward, which would act more as breakers than turners. Yet it is the first use of iron for the turn-furrow. Then follows France with an iron wing on each side of the plough that bears some remote resemblance to a modern turn-furrow, which very soon after this period became somewhat perfect. Germany followed close in the wake of France, and by some writers has been supposed foremost in maturing the iron turn-furrow. They certainly were the first to use the skin coulter in front of the plough.

It is a race between England, France, and Germany for the authorship of wheels to ploughs, but to England is due the honour of using them to greater perfection, and also for making the whole of the agricultural implements lighter and handier, and freeing them from the whole of those barbarous lines which mark them in their early production, and which still cling to the French and German ploughs.

Thus, bit by bit, the plough has attained its present perfection, but we use the word perfection in reference only to cutting a solid even furrow, for we believe that this solid slice is one of the disadvantageous features of the modern plough, and it does much more harm than good. Hence arises the dispute between so many of the great agriculturists of the day between the solid and the broken furrow.

We purpose pursuing this subject further in another communication, in which we shall institute a comparison between English and foreign ploughs.—We are, Sir, yours, &c.,

F. and C. HANCOCK, Engineers.

Plough and Screw Propeller Works, Dudley, August 28.

ELECTRIC SEA CABLES AND LAND WIRES.

SIR,—I wish to point out to your readers the superior conductivity of aluminium wire over copper, and, therefore, its efficiency for telegraphs. It does not, I believe, solder; but the joinings of the copper wires do not appear to be made by solder, but by splicing closely sealed. As to the endurance of aluminium under electric action I cannot speak, and I do not think it has ever been tested; but it, of course, can be easily subjected to continuous powerful currents so as to test its durability and point of fusion and the effect produced on coatings by gutta-percha.—I am, Sir, yours, &c.,

VERITAS.

Ayr, September 11.

WINDOWS OF CHURCHES AND CATHEDRALS.

SIR,—There has of late years been a considerable advance in ornamental architecture by introducing tinted and painted glass windows into churches and cathedrals. It has struck me that effects singularly beautiful and grand would be obtained by filling special windows with crystal. Windows with a southern aspect would perhaps suit best, particularly the Gothic rose and Pointed arch windows. No kind of painting could exceed in beauty and effect a window throwing prismatic colours; and although it would necessarily be somewhat expensive, it would be less so than painting or enamelling, and would have the quality of rare effect and uniqueness.—I am, Sir, yours, &c.,

VERITAS.

Ayr, September 11.

EFFECT OF STEAM ON GASES.

SIR,—I wish to draw the attention of your readers to the power of steam in absorbing gases. This property might be used as a means of purification, and also of freeing mines from fire and choke-damp. It is easily generated, easily applied, and very diffusible. The action naturally takes place in the atmosphere, the vapour in which absorbs carbonic acid, ammonia, and other gases, and sends them down in solution in rains. Rain water collected pure (as in the midst of sand-hills) is frequently distinctly acid in taste from the presence of carbonic acid. In confined places, where carbonic acid has been generated, steam immediately relieves its effects. This property seems to arise from the vesicles of the vapour or steam getting filled with the gas and retaining it until condensation takes place, after which a solution is formed. Water itself has a powerful effect in absorbing and retaining gas; and I think the application of the property of steam to mines, cellars, vats, ships' holds, and all places where foul gases exist makes the discovery one of considerable moment.—I am, Sir, yours, &c.,

VERITAS.

Ayr, September 11.

THE ATOMIC THEORY.

SIR,—I have observed that at the meeting of the British Association at Exeter, the President of the Department of Chemical Science declared the return of modern science to the atomic theory of the ancients. After a lapse of twenty centuries, with our superior knowledge and scientific acquirements, we accept in an indirect manner the ideas of those great minds that propounded so important a theory with the imperfect knowledge they possessed. To establish the above we require a knowledge superior to that of the laboratory. The recent solar observations have opened to us a wide field for philosophic inquiry. It is, then, not in the partial decomposition of an element that we must seek the establishment of a theory so ancient and so philosophical. The question of heat has always been the stumbling block of science, and until the nature of both cold and heat have been scientifically explained we may seek in vain to extricate ourselves from the difficulties in which we are involved. It was in the solution of this question that the actual condition of our central body (since verified by recent discoveries) was foretold in the columns of the MECHANICS' MAGAZINE. The iteration of that which has been published would be useless. But in that hypothesis, briefly and imperfectly explained, will be found the real basis of the most philosophical theory of antiquity.—I am, Sir, yours, &c.,

H. SALOWAY.

13, Standard-street, Dover-road, Sept. 12.

HYDROSTATIC STEERING APPARATUS.

SIR,—In your issue of the 27th ult., is a notice of a hydrostatic steering apparatus invented by Admiral Inglefield, who uses the weight of the ship to steer it, and your notice says, "we understand it is cheaper than any other mechanical apparatus yet tried"—"the power it utilises costs nothing," &c. Both these assertions are mistakes, as can be shown. It requires twenty-five men to steer the ship by the ordinary method; now, let us assume each man's work equals 25 foot pounds, the twenty-five men's work would slightly exceed 1,000 tons lifted 1ft. high per hour. Keeping this in mind, let us ask what becomes of the sea water after doing its work in the large cylinder? It cannot flow back to the sea, otherwise we should have something more than perpetual motion. It has to be pumped out of the ship, and the amount to be pumped out will be equivalent to 1,000 tons lifted 1ft., *plus* the amount required to overcome the friction of the extra apparatus. If this work is done by manual labour, fifty men instead of twenty-five would be the number required to keep the ship clear of this water. We may assume, however, this work to be done by the ship's engines, thus necessitating distinct pump machinery for the

purpose, the weight of which, in addition to the weight of cylinder with its piston, rod, barrel, &c., will amount to a good round weight, to be constantly carried about whether in use or not. It is a fallacy to state that "the power is always ready at hand for use." Steam will always be required when the apparatus is in use. Therefore, since it is a question of fuel, we have only to consider which is the cheapest in the long run—the Admiral's gigantic low-pressure apparatus, or special steam hydraulic machinery. My belief is the latter would not be half so expensive to the country as the former, and as an economist I join you in hoping the Admiralty will have its eyes opened to the value of the Admiral's system.—I am, Sir, yours, &c., ROBERT SHENTON.

9, Victoria-place, Millwall, August 28.

PROPOSED ABOLITION OF PATENTS.

SIR,—The MECHANICS' MAGAZINE of August 27 copies an article from the "Engineer," in which "The Abolition of Patents for Inventions" is severely handled:—"The hon. member must needs insult our gracious Sovereign by writing her down as of the neuter gender." "'The Sovereign voluntarily puts itself,' writes Mr. Macfie at p. 74." If you will be good enough to turn up the passage, you will find that the charge made against me is baseless. Allow me to present the *ipsissima verba*:—"The purchase is a compulsory one, with this peculiarity, that whereas the inventor may or may not offer to sell—for he is left at perfect liberty, as in a free country he ought to be, whether to patent and reveal (sell) or not—yet, if he do offer, it is the State, the maker of the law, which, through the Sovereign, voluntarily puts itself under compulsion to accept the offer."—I am, Sir, yours, &c., R. A. MACFIE.

Ashfield Hall, Neston, August 30.

[The delay in the insertion of the above letter has been accidental.—ED. M.M.]

TO CORRESPONDENTS.

THE MECHANICS' MAGAZINE is sent post-free to subscribers of £1 1s. 8d. yearly, or 10s. 10d. half-yearly payable in advance.

All literary communications should be addressed to the Editor of the MECHANICS' MAGAZINE. Letters relating to the advertising and publishing departments should be addressed to the publisher, Mr. R. Smiles, MECHANICS' MAGAZINE Office, 166, Fleet-street, London.

To insure insertion in the following number, advertisements should reach the office not later than 5 o'clock on Thursday evening.

We must absolutely decline attending to any communications unaccompanied by the name and address of the writer, not necessarily for insertion, but as a proof of good faith. ED. M. M.

Advertisements are inserted in the MECHANICS' MAGAZINE, at the rate of 6d. per line, or 5d. per line for 13 insertions, or 4d. per line for 26 insertions. Each line consists of about 10 words. Woodcuts are charged at the same rate as type. Special arrangements made for large advertisements.

MR. R. W. ROW, of High-street, Alton, writes us complaining that we should state, in our notice of his specification, No. 383, at page 180 of our issue for the 3rd inst., that the patent was abandoned, which he says is an error We have inquired into the matter, and find that our notice is correct. The patent was abandoned, and this in consequence of the agent having made the mistake of supposing that he had six months from the date of sealing the patent for filing his final specification. Instead of this—as every agent ought to know—the time is six months from the date of lodging the Provisional Specification. This is one of the results of employing incompetent agents, and is the second case of the kind that has come under our notice within the last few months.

IN our last issue it was stated in the Abstracts of Specifications, that the patent No. 404, J. H. Johnson, had been abandoned. This on inquiry, we find to be an error; the patent having been sealed July 20, and the final specification filed August 7 last.

RECEIVED.—C.R.—J. S. W.—S. and Co.—G. E. P.—H. S.—J. H.—T. W.—E. E.—J. K.—S. E.—C. G. L.—R. M.—H. R. D.—J. H. and Co.—R. S.—J. W. and Co.—R. A. M.—S. G.—R. S.—T. L.—C. W. R.—J. H.—F. P. and Co.—J. H.—J. B. and Co.—H. T.—F. R.—H. J.—T. and B.

Naval, Military, and Gunnery Items

A LETTER dated from the Admiralty, September 13, signed Vernon Lushington, states that the Lords Commissioners of the Admiralty had come to no decision as to the abolition of Sheerness as a naval establishment, and that they, in fact, had never considered the question.

LONDON is at last to have a direct line of steamers from Colon and the West Indies, the West India and Pacific Steamship Company (Limited) having arranged for a monthly line homewards to commence in January next. By the new route, produce will be brought from ports in Central America, California, and on the South Pacific, *via* the Isthmus of Panama, to London.

THE Coastguard service is in future to be one of a more active character than it has hitherto been. We understand that all the captains have received notice from Whitehall that they must be prepared to man their ships and to go to sea for the purpose of exercising and drilling their men every three months.

THE flagship "Formidable," 78 guns, which has been granted by the Government as a training ship for destitute boys of Bristol, has arrived from Sheerness, and is stationed off Portishead. Commander Edward Poulden, R.N., has been appointed Captain Superintendent. The "Formidable" left Sheerness on Monday week, and was towed round by a Liverpool steam tug-boat. She encountered a rough passage, and did not reach Portishead till Saturday afternoon.

THE mitrailleur gun, of which Major Fosberry, V.C., of the Bengal Staff Corps, has had charge, and upon which he has made some alterations, is now placed under the direction of a committee, of which Colonel Wray, C.B., R.A., is president, and will be reported upon to the Secretary of State for War after being put through various trials at the Select Committee Range at Woolwich.

EARLY on Friday morning the new floating and tidal docks at Belfast were flooded by a high tide breaking in a portion of the embankment. It is stated, however, that no injury to the docks has been sustained, as every precaution had been taken to guard against such a contingency. The works are in an advanced state, and the embankment itself was about to be cut away in a few days in order to allow the water to flow into the basin.

THE San Francisco "Bulletin," of September 14, publishes a letter, which it declares to be authentic, stating that documents have been found, near San Buenaventura, giving a detailed account of the desertion of the ships "Erebus" and "Terror," of Sir John Franklin's expedition. According to these documents, the party wintered in 1846 to 1847 at Beechy Island. Sir John Franklin died on June 11, 1847. The papers had evidently been thrown overboard about lat. 59½, long. 98.

DURING the recent cruise of H.M.S. "Blanche," when under full steam at full speed, the sudden alarm of "a man overboard" called everyone to his station. A boy had fallen from the rigging. The life buoy was promptly let go, engines stopped and reversed, life boat lowered, the first lieutenant, boatswain, and the boy picked up, boat hoisted up, and ship going ahead at full speed again in nineteen minutes five seconds. This we may call smart work. Lieutenant Markham and the boatswain had both jumped overboard to save the life of the youngster.

ON Wednesday, August 18, about 40ft. of Buffalo Arsenal fell, carrying with it 30,000 rounds of ammunition. The keeper of the Arsenal, who had been in that portion of the building only a few moments before, had a narrow escape of instant death. And had the accident occurred the evening previous, a large loss of life would have been occasioned, as the 65th U.S. Regiment assembled therein on that evening for drill. Measures will be immediately taken to have the building made more secure.

THE Austro-Hungarian delegations have decided to vote funds for the establishment of a flotilla of monitors on the Danube. These monitors are only to draw 1½ft. of water; each of them will be armed with a gun of the heaviest calibre, and their sides will be protected by plates from 3in. to 8in. thick, made of the best Styrian steel, and provided with joints of teak. As they will have to carry a heavy weight, and at the same time draw very little water, they will be very broad and flat-bottomed.

Miscellanea.

THE imports of iron minerals into France in the first six months of this year have been officially returned at 278,786 tons; of this total 108,228 tons came from Algeria.

MR. TITUS SALT, of Saltaire and Crow Nest, Yorkshire, has received the offer of a baronetcy, which he has accepted. This honour is regarded with unmixed satisfaction by all classes in Bradford.

AN order for 6,000 tons of iron has come to hand in Belgium in connection with a bridge to be constructed at Hamburg; another order for 1,500 tons for Lisbon is also noted.

THE number of visitors to the Patent Office Museum, South Kensington, for the week ending September 11 was 5,296. Total number since the opening of the Museum, free daily (May 12, 1858), 1,641,793.

AT a meeting of the Inverness Town Council held on Monday, and specially called for the purpose, a proposal was submitted by Bailie Simpson for conferring the freedom of the burgh on Sir Roderick Murchison, LL.D. The proposal was unanimously agreed to, and the town clerk was instructed to ascertain from the hon. baronet when it would be convenient for him to accept the honour. Sir Roderick is a native of the neighbouring burgh of Dingwall.

THE Humboldt centenary will be celebrated in London at the great hall of the German Turn Verein, where M. Karl Blind has been invited to deliver the festive speech.

THE last of the Mamelukes, Sidi-Ferdouck by name, has just expired at Balana, a small village on the Mediterranean coast. The defunct Sidi was a friend of the Emperor's celebrated Roustan, and served in the Consular Guard, his turbaned squadron creating no small effect in the Carrousel. Sidi fought in Italy, Germany, Spain, and Russia, and altogether must have had a hard time of it in his youth.

A CENSUS of Oude, taken last February, shows that the population is so much as 11,220,747, instead of 8,000,000, as was always estimated. Of these only 1,195,879 are Mahomedans, 6,431 Christians, and 10,002,731 Hindoos. This raises the population of India, without the Feudatory States, to 156,000,000, and of all India to 205,000,000, estimating Bengal at only 38,500,000.

AUSTRALIAN papers state that a number of fine pearls discovered at the fisheries carried on in the vicinity of Nicol Bay, Western Australia, have been exhibited in Melbourne. They are of great size and beauty, the most valuable among them resembling in shape and dimensions the eyeball of a large fish. This is said to be worth upwards of £200.

THE Minister of Public Instruction in France, some time since, founded a museum of anthropology, and confided its direction to M. Quatrefages, member of the Institute. This museum has just been enriched by a collection of types, life-size, of the natives of the Valley of the Nile, painted by M. Georges Lefebure, who has returned from a mission to the East.

THE number of visitors to the South Kensington Museum during the week ending September 11, 1869, was—on Monday, Tuesday, and Saturday (free), from 10 a.m. to 10 p.m., 14,747; Meyrick and other galleries, 2,348; on Wednesday, Thursday, and Friday (admission 6d.), from 10 a.m. till 6 p.m., 1,606; Meyrick and other galleries, 148; total, 18,849. Average of corresponding week in former years, 12,064. Total from opening of Museum, 8,792,855.

THE exports of rails from Belgium continue to show an increase, having amounted in the first half of this year to 41,895 tons, against 24,597 tons in the corresponding period of 1868, and 13,930 tons in the corresponding period of 1867. The imports of minerals into Belgium have largely increased this year. The exports of coal from Belgium in the first five months of this year amounted to 1,397,061 tons, against 1,402,629 tons in the corresponding period of 1868, and 1,332,840 tons in the corresponding period of 1867.

WE have tried many pens of various kinds and qualities, but have not had one which we could really say we liked until chance brought us across the "Waverley" pen. This pen, which has been introduced by Messrs. Macniven and Cameron, of Blair-street, Edinburgh, is admirably suited for rapid editorial writing. The secret of its smooth action lies in the fact that the points are slightly turned back, and until the metal is corroded the pen never becomes "scratchy." The "Pickwick" pen makes a somewhat finer line, but we commend the "Waverley" to all knights of the pen.

ATTENTION has been lately drawn by the "Journal of Franklin Institute" to a curious observation which stands, as yet, as a fact without a sufficient reason. In one case, where hard coal is used in large quantities for purposes of mere evaporation, it appears that some which has been kept on hand in open piles for five or six months is less effective by from 13 to 15 per cent. than that freshly mined. A similar result, corresponding even in the percentage of deterioration, appears in another report from a smelting furnace. The deterioration from decrepitation, caused by absorption of water, is of course well known, but does not seem to apply to these cases.

THE Society of Arts programme of examination is materially altered. Many subjects are omitted, and some are introduced to give a more practical character. A memorandum from the treasurer, Mr. Hyde Clarke, explains a system of *viva voce* examinations in modern languages, more particularly intended to encourage working men to make themselves useful as foremen and directors of labour in India and in foreign countries. It is proposed that the candidates may obtain a certificate for ordinary conversation alone, and with particular reference to the technical terms of his trade. The system is used in the vernacular examinations for the Indian services.

IT having been reported to the Queen that the annual prize of twenty-five guineas, given for the last eight years in the name of the late Prince Consort through the Society of Arts, had been three times obtained by the City of London College for Young Men, and, for the last two years, by the Polytechnic Evening Classes, Her Majesty has been graciously pleased to present copies of the "Early Years of H.R.H. the late Prince Consort," and "Leaves from the Journal of Our Life in the Highlands," to each of those societies.

THE chimney of a flour mill, at Fairfield, Iowa, recently fell, causing the destruction of the entire mill. The catastrophe was caused by turning the escape steam into the brick flue near its base, and at this point the bricks could be crushed between the fingers, while the balance of the chimney was perfectly solid. It is strange that such errors can be committed by thinking men as to let such a subtle agent as steam in upon such an absorbent material as brick. With the exception of oil, there is no more searching power than that possessed by steam, and when we consider how liberally brick admits water into its pores, we cannot be surprised to see what the effect of the injection of steam must be on it.

M. LIEBREICH has presented a memoir to the Academy of Sciences, which contains some interesting details concerning a new anæsthetic he has just discovered. An important difference between this new chemical compound, which he calls chloral, and all other substances used for the purpose of producing insensibility, is that it is administered by absorption instead of inhalation, and this enables the dose applied to be measured with greater accuracy. On passing into the system it becomes decomposed into formiate of potassium and chloroform, and produces more perfect insensibility than either ordinary chloroform or ether. Its use is said to be unattended by any danger. In a very painful and difficult operation lately performed on a woman, M. Liebreich applied chloral with perfect success, the patient being kept under its influence for over two hours.

ACCORDING to the American journals, a novelty in railway management is to be introduced by the Erie Company, who propose to illuminate the whole of that road by night by electric lights at the ferries, in the tunnels, on all dangerous curves, and on every engine. Mr. E. C. Morse, who has charge of the matter, states that he has made several important improvements, among others a plan for preserving the carbon points from wasting away, and keeping them for months in a good condition, a self-sustaining battery, and an invention by which the turning of the wheels of the engine shall collect electricity for use in illumination. There will be a light at each end of the ferry, which, it is believed, will make a collision practically impossible on the darkest and foggiest night. Even with the diminution of light caused by the jarring of the locomotive, it is estimated that the head-lights will show the track to the engineer on a straight line for three miles.

A NEW wrought-iron chimney has been recently erected at the Creusot Ironworks. It is 197ft. high, and 6ft. 7in. diameter. At the bottom the diameter is increased to 10ft. by a curved base, which is fastened by vertical bolts to masonry work. The thickness of the sheet iron is 3-32in. at the top, and 7-16in. at the bottom. There is an inside iron ladder. The weight of this chimney is forty tons; it has been riveted horizontally, and lifted afterwards with a crane. Another one, 275ft. high, will be soon erected, but by a different system; it will be riveted vertically, with an inside scaffolding. These chimneys are built for an extension of the Creusot Works, especially intended for steel making. There will be eight Bessemer converters, where the cast iron will be run direct from the blast furnace; there will be also many Martin's furnaces, and an extensive workshop for melting steel in crucibles, where it will be possible to melt together fifty tons of steel.

THE material generally used by watchmakers on the continent for polishing hard and soft steel as well as brass is a white substance called wiener kalk; it polishes much quicker than crocus, and with a beautiful black gloss. The "Horological Journal" states that it is used in the following manner:—The piece to be polished is first put on a piece of cork fastened in the vice, and rubbed with a piece of plate glass, on which is put a little oil and oilstone dust, till it is perfectly flat and all the file marks have disappeared. It is then cleaned with a brush and soap and water, and dipped in spirits of wine; and, after being dried with a clean cloth, put on another clean piece of cork, in the same way as before, and rubbed briskly with a flat polisher, made either of bell metal or block tin, in which is put a little wiener kalk and fine oil, mixed to the consistency of a thick paste. It is necessary to prevent any dust getting in the polishing stuff or on the piece to be polished.

THE American papers, in their comments on the great feat of reporting the result in America by the Atlantic Telegraph within 23 minutes of the race, state that a portion of this time was occupied in taking the despatch to the Mortlake telegraph station by a messenger on horseback. This is a mistake. The despatch was carried to the telegraph-office by a very fast runner in the service of the Electric Telegraph Company, who is employed on all important occasions by the intelligence department on account of his reliability and great speed. His name is Lewington, and he is known in the service as "Electric Jack." On the occasion of the prorogation of Parliament he ran with the copies of the Queen's speech from Westminster to the chief office in Moorgate-street in 14¼ minutes—a very fast performance, considering the crowded state of the streets during the middle of the day.

Patents for Inventions.

ABRIDGED SPECIFICATIONS OF PATENTS.

THE Abridged Specifications of Patents given below are classified, according to the subject to which the respective inventions refer, in the following table. By the system of classification adopted, the numerical and chronological order of the specifications is preserved and combined with all the advantages of a division into classes. It should be understood that these abridgments are prepared exclusively for this Magazine from official copies supplied by the Government, and are, therefore, the property of the Proprietors of this Magazine. Other papers are hereby warned not to produce them without an acknowledgment:—

BOILERS AND FURNACES—510, 513, 537, 569
BUILDINGS AND BUILDING MATERIALS—493, 499, 518, 535, 548, 570, 578
CHEMISTRY AND PHOTOGRAPHY—481, 563, 574
CULTIVATION OF THE SOIL, including agricultural implements and machines—489, 492, 506, 572, 541, 552, 534, 577
ELECTRICAL APPARATUS—501, 531
FIBROUS FABRICS, including machinery for treating fibre pulp, paper, &c.—480, 496, 497, 502, 509, 515, 526, 530, 540, 543, 547, 573, 579
FOOD AND BEVERAGES, including the apparatus for preparing food for men and animals—539
FURNITURE AND APPAREL, including household utensils, time-keepers, jewellery, musical instruments, &c.—482, 483, 491, 504, 508, 555, 562, 582, 583
GENERAL MACHINERY—487, 490, 500, 507, 516, 551, 567
LIGHTING, HEATING, AND VENTILATING—523, 536, 561, 575
METALS, including apparatus for their manufacture—524, 546, 566
MISCELLANEOUS—484, 485, 494, 495, 505, 520, 521, 527, 528, 534, 542, 549, 559, 563, 571, 576
ROADS AND VEHICLES, including railway plant and carriages, saddlery, and harness, &c.—486, 498, 517, 522, 544, 550, 553, 556, 564, 568
SHIPS AND BOATS, including their fittings—503, 538, 545
STEAM ENGINES—481, 519, 525, 529, 560, 572
WARFARE—371

---

480 T. SAGAR and T. RICHMOND, Burnley. *Looms* Dated February 17, 1869.

The warp on leaving the warp-beam is taken, as usual, over the vibrator or other equivalent, then over and under a pair of lease-rods mounted on swivel-links which are made to vibrate by a lappet on the lappet-shaft, or other suitable part of the loom, then under a rod or roller extending across the loom, and then through improved healds or healds of the usual construction. The warp then passes through the reed and thence to the take-up roller, as usual.—Patent abandoned.

481 J., B., and R. WOOD, Sowerby-bridge. *Steam engines.* Dated February 17, 1869.

This consists in the application of a separate small steam cylinder and piston with ordinary slide valve; the piston rod thereof is connected with another rod in communication with and giving motion to the spindle of the cut-off valve. The valve rod is provided with two collars or shoulders, between which are two cams mounted upon a hollow spindle, within which works a sliding rod connected to the governor by a bell crank lever and connecting rod. In the sliding rod are fixed two projecting studs or pins passing through slots cut or formed in the hollow spindle parallel to its axis, and made to enter into oblique slots formed in the cams respectively, so that when the sliding rod is moved in either direction in the hollow spindle, the projecting studs or pins will move the cams thereon, altering their position, and thus giving motion to the piston in the cylinder, and thereby move the spindle of the cut-off valve; and by the varying action of the governor causing the steam to be cut off sooner or later, and the action of the governor being quick, the cut off is quickly effected.—Patent completed.

482 E. T. HUGHES, Chancery-lane. *Washing machines.* (A communication.) Dated February 17, 1869.

The machine is composed of a frame supporting the vessel, in which the process of fulling or washing takes place, and which consists of a case resting on the ribs of the frame. The vessel, at the bottom of which are the heating tubes and the discharge orifice, is lined on the interior with a layer of marble, hard slate, or other stone or porcelain, and the beaters pivoting on the axis are also covered with a layer of such material, so that the linen shall only come in contact with perfectly clean and unchangeable surfaces. The point on which the levers operating the beaters oscillates is placed between the said beaters and the crank or eccentrics working in close proximity to the beaters as usual in the present time. For single-action washing machines, where the crank is placed laterally, this would not be inconvenient, but in double-action washing machines it is necessary that the cranks and the mechanism generally should be arranged in the interior of the casing, which renders access to these parts difficult, so that stains caused either by drops of oil or (in case of insufficiency of lubrication) by particles of rust from the bearings become inevitable.—Patent completed.

483 J. ATKINS, Birmingham. *Metallic furniture.* Dated February 17, 1869.

This consists in improvements in manufacturing the head and foot rails or ends of metallic bedsteads and other articles of metallic furniture. The head and foot rails are usually made of rods joined together by cast or other junctions, or of panels inserted in a framing of tubes. In making the head and foot rails according to the invention, the inventor constructs a framing of a rectangular figure by means of flat bars, which framing may be divided into smaller rectangular divisions by parallel flat bars. The rectangular spaces thus formed are filled by straight strips of sheet metal, arranged either diagonally or parallel with the sides of the framing, or the strips may be interlaced. Where the strips cross each other and where they join the flat bars of the framing he connects them together by plain or ornamental rivets or otherwise. Any required ornaments may be attached either at the crossings of the strips or in the open spaces. The flat bars and strips described may be ornamented with surface or other ornaments.—Patent completed.

484 E. ROUND, Sheffield. *Cooling and warming vessels* Dated February 17, 1869.

This consists in constructing vessels with an inner vessel or receptacle and leaving a space or spaces between them into which ice or a cooling matter or mixture may be introduced for the purposes of cooling, and hot water or a warming matter for the purpose of warming, any fluid or material that may be put in the inner receptacle and be kept distinct therefrom, and in furnishing the outer vessel with a false or double bottom and leaving a space between them. The false or upper bottom is furnished with suitable holes or outlets for inserting the cooling or warming material, and for drawing off the water or liquid from the ice or cooling matter when necessary, and so keeping the ice or cooling matter when applied to the space between the outer vessel and its receptacle or inner vessel free from wet or too much moisture, whereby it and a low temperature is longer preserved.—Patent completed.

485 W. E. NEWTON, Chancery-lane. *Stamps.* (A communication.) Dated February 17, 1869.

This consists chiefly in constructing the stamps with a hole or holes through the body of them, and covering or backing the same with tissue or other thin bibulous paper made to firmly adhere to the body and the rear surface of the stamp with its bibulous paper covering to the hole or holes coated or backed with mucilage or other adhesive substance.—Patent abandoned.

486 F. H. COLLINS, Kensington-gardens. *Permanent ways.* (A communication.) Dated February 17, 1869.

It is well known that railroad rails have sometimes been made double or reversible, so that in the event of the upper or bearing surfaces of the rail becoming worn and unsafe, the rail could be turned over and a new bearing surface brought into use. But such reversible rails have been usually made in the shape of a double T, that is like two ordinary T rails having their bases joined together. The invention consists in a form of rail which, while avoiding all the obvious disadvantages of the double T rail, yet possesses all its valuable properties.—Patent completed.

487 A. RANSOME, King's-road, Chelsea. *Wood-cutting machinery.* Dated February 17, 1869.

This relates to the planing part of the machine, in which the inventor employs two rotary adze blocks provided with cutters. One block is intended to plane the upper surface of the wood, and the other to plane the under surface. The wood rests upon and is drawn or pushed along a table, in which is made an opening for the lower rotary planing tool or cutter to act on the wood. The spindles on which these cutter blocks are fixed or secured are distinct from the saw spindle, and are actuated from the driving shaft by means of separate gearing consisting of bands and pulleys, so that either the planing tools or the saw may be worked or stopped without interfering the one with the other. When required, the rotary planing adze blocks and cutters may be removed from their spindles and tenoning blocks may be substituted for them and secured on the spindles. Cutters may be secured to the planing blocks for cutting single or double mouldings.—Patent completed.

488 W. R. LAKE, Southampton-buildings. *Extracts from coal gas.* (A communication.) Dated February 17, 1869.

This consists in placing coal gas in contact with substances which act as solvents for the benzole and homologues contained therein without, at the same time, causing them to undergo any chemical change, and while it has been found that all known solvents of benzole will effect this purpose, the inventor prefers to place coal gas in contact with certain hydrocarbons such as petroleum, schist, and mineral oils, and the higher boiling varieties of coal tar, naphtha, as these hydrocarbons are easily procurable and interfere little, if at all, with the illuminating power of coal gas, and by mere distillation the benzole and its homologues may be separately obtained from their solution therein and the solvent rendered again fit for renewed application.—Patent completed.

489 H. D. BOWYER, Ripley, and J. L. NORTON, Belle Sauvage-yard, E.C. *Wheaten flour.* Dated February 17, 1869.

This consists in subjecting wheat to the action of steam or moisture to such an extent that it takes up sufficient moisture to permeate the husk or bran, after which the wheat is dried in order to cause a contraction of the grain with the object of loosening the husk or bran so as to cause it to separate more freely from the farina or flour, or the moistening of the grain may be omitted and the wheat simply be passed through a drying machine to dry it. After the wheat has been dried it is then crushed by being passed through rollers of metal, or other material either fluted or plain. The wheat is delivered to the rollers in an even stream or thickness by a shaking screen feed motion, which screens the wheat and frees it from dust and small seeds before it enters or passes into the crushing rollers.—Patent completed.

490 H. ALAND, Surrey. *Rotary blowing fans.* Dated February 18, 1869.

This consists in introducing a vertical partition or partitions with central openings in one fan case, thus forming separate fan chambers with inlet openings into their respective fans.—Patent abandoned.

491 F. J. KNEWSTUB, Westminster. *Writing cases.* Dated February 18, 1869.

The inventor constructs the leaves or partitions separately and distinctly from a despatch box, and he applies them or the case containing them to cases, boxes, drawers, or receptacles of any description; the leaves or the case with the leaves may be made in such a manner that they may be used in an upright position separately, or may be made so as to lie flat upon a table, with or without the alphabet, numerals, symbols, or devices impressed, printed, or fitted thereon so as to be observable from above. In order to facilitate the leaves being moved the inventor arranges them upon wires or bars fitted inside the case or in a frame or tray.—Patent completed.

492 J. DARLINGTON, Moorgate-street-chambers. *Drilling apparatus.* Dated February 18, 1869.

This consists in a peculiar combination and application of certain known mechanical forms and movements towards simplifying and rendering more effective the action and consequent force applied to the drill used for boring rocks or mineral substances. The improvements consist in the use of a screw or of a rod having spiral slots in connection with certain wheel gearing, the whole being so arranged and combined that if rotary motion be given to the screw a simultaneous and similar motion is communicated to the drilling bar.—Patent completed.

493 A. BARTHOLOMEW, Glasgow. *Sliding windows.* Dated February 18, 1869.

The inventor applies a plate or plates, or surface or surfaces to the side or sides of the upper sash with holes tapped to receive a screw with a square or other head adapted to receive a loose key, by which such screw is placed in position, and when in position, by acting on the upper part of the lower sash to prevent the one from being raised and the other from being lowered beyond a suitable distance, which may be varied by the position of the screw in the upper sash.—Patent completed.

494 A. MUNRO, Arbroath, and W. B. ADAMSON, Glasgow. *Masons' tools.* Dated February 18, 1869.

This consists in the construction of conical tubular tools. The tools under the first modification constitute a hollow truncated cone or short conical tube. The tools are fixed in the holders of the machine for cutting stone, slate, marble, rock, or other substances, preferably by means of a bolt, which passes into or through the hollow or tubular part of the tool, on or in the other end of which a nut, spring, or cotter is placed, or the bolt may be made to tightly fill the hole in the socket, in which case the nut, spring, or cotter is dispensed with. The bolt on being tightened draws the tool firmly into the recess formed in the socket or holder to contain it. Under a second modification the tool is made hollow for a certain length, only the after part forming a solid shank or bar, which passes into a correspondingly formed hole in the socket or holder, and by which it is held therein. The tools constructed under the first modification are to be formed of chilled iron, steel, forged or pressed into the requisite shape, or of chilled or forged compounds or alloys of iron or steel. The tools constructed under the second modification are to be made of chilled iron or of chilled compounds, or alloys of iron or steel.—Patent completed.

495 A. GARRISON, Birmingham. *Pendant string holder.* Dated February 18, 1869.

This consists in forming them, by preference, of a spherical form, in two parts, principally from wire gauze raised into the desired shape, each part or half being bound by a tinned or other metal rim and united together in any convenient portable way, such as by a hinge and catch, and on the apex of the one half or semi-sphere a strong ring or collar is applied for the convenience of portable suspension.—Patent abandoned.

496 J. D. NICHOL and J. ECKERSLEY, Edinburgh. *Paper apparatus.* Dated February 18, 1869.

This consists in the combination and arrangement of hollow drums, heated by steam or otherwise, over and under and in contact with which the printed sheets of paper are separately passed, and thence through a pair of pressing rollers, when they pass successively into a suitable box or receptacle.—Patent completed.

497 C. BROOK, L. BARKER, and M. THOMPSON, Halifax. *Looms.* Dated February 18, 1869.

This relates to the take-up motion in looms for weaving, or the means or apparatus to be employed for effecting the regular winding on to a beam or roller of the woven fabric as produced, and so that when occasion requires, either by the breakage of the weft or when it is used up, such taking up may cease at the proper place or the beam turn back to it, and at any time the turning back of the beam or roller may readily be effected. For this purpose the inventors apply a short shaft gearing at one end with either the crank shaft or the tappet shaft, as most convenient, by suitable wheels to produce the required rotary motion, and at the other end gearing by means of worm and wheel with the ordinary taking-up gear wheels, or a new arrangement of similar wheels, and so that this end of the shaft may be readily lifted or removed out of gear. To effect this it is attached to a lever fixed on one end of a rod or shaft extending across the loom under the breast beam and supported in the loom ends, and on the other end is fixed another lever, projecting up through the breast beam, and so set that when the weft fork lever is acted upon it will act upon this lever, and thus lift the shaft out of gear with the taking-up wheels, and an adjustable slip catch is also applied to the ratchet wheel for holding the take-up constructed with a slot, so that it may be set by an adjusting screw to let slip or expand to any desirable extent, and thereby allow the beam to turn back the required distance.—Patent completed.

498 R. PYNE, Wellington-street, Strand. *Carriage steps.* Dated February 18, 1869.

Upon the bottom end of the carriage door is affixed a stirrup or suspender, turning freely with the door. Attached to this is a step of wood or metal, so arranged that when the door is shut it projects underneath the carriage, but when the door is opened it radiates from the stirrups and projects in front of the door in a line with the carriage so as to form the step. A guide bar underneath serves both to guide and support it.—Patent abandoned.

499 J. A. WADE and J. CHERRY, Hornsea. *Brick press.* Dated February 18, 1869.

A suitable frame, mounted on wheels or otherwise, carries the fixed die or mould (for forming the sides of the brick, tile, or other article), to which is hinged the movable upper die or lid. The lower die or loose bottom, which works vertically inside the fixed die or mould, and by which the pressure is given, is supported upon two eccentrics keyed upon a shaft capable of revolving in bearings fixed to the frame, and having a hand lever keyed at one end thereof. The hinged upper die or lid, when closed, is held down by a catch, but when released by a cam on the eccentric shaft or a pin on the lever, is thrown back by means of a spring.—Patent completed.

500 T. H. MARTIN, Swansea. *Piston tightener.* Dated February 18, 1869.

This consists in an improved mode of tightening the piston rings of pistons so as to make them fit more exactly in the cylinders, thereby keeping their places better, and exerting more power than hitherto. This improved method is accomplished by placing a movable valve or valves in the body of the piston, which valves are opened and closed by the working pressure (of whatever kind, whether of air, steam, water, or gas, or of other fluids or liquids) on either side of the piston, thereby causing a continual pressure (equal to the working pressure on either side of the piston) to act against the inner sides of the metallic rings composing the piston, thus continually pressing them against the sides of the cylinders, whilst the engine (to which the piston is attached) is at work.—Patent completed.

501 D. G. FITZGERALD, Battersea. *Telegraph voltaic batteries.* Dated February 18, 1869.

This consists in the insulation of a signalling current, not as hitherto by means of a dielectric or insulating material, properly so termed, but by means of good conductors of electricity (metals and electrolytes), so arranged as to generate an electro-motive force, which opposes the escape of the signalling current when the latter is transmitted in a particular direction. Or, in other words, the inventor prevents the passage or escape to earth of the signalling current by generating an electro-motive force, which is made to oppose such passage or escape of the signalling current, thus allowing it to complete the line circuit. This mode of insulating the signalling current he terms "electrolytic insulation," to distinguish it from the ordinary mode of or from "dielectric" insulation.—Patent completed.

502 J. NEWTON, Leeds. *Spinning flax.* Dated February 18, 1869.

In place of making the supports, which carry the saddles, with projecting pins to enter into slots in the saddles the inventor forms the support with two parallel cheeks, between which the centre portion of the saddle is received. A pin carried by these cheeks, and passing across the space between them, enters a slot in the saddle, and the saddle is thus supported. The saddle is formed with parallel sides, which fit between the two parallel cheeks of the support; consequently, the cheeks may be formed to fit against the sides of the saddle for any desired portion of its length, whilst the central portion of the saddle, in which the slot is made, and which fits between the cheeks, may also be made of sufficient depth to give steadiness. By thus constructing the saddles and their brackets or supports, a large bearing surface is obtained to present any lateral motion of the saddle, and in addition as the sides neither of the saddle nor the brackets have any projections from them they may be fitted by grinding or filing at a very small cost.—Patent completed.

503 W. DAINES, Gravesend. *Anchors.* Dated February 18, 1869.

This consists, chiefly, in constructing the stock with inclined pieces, which extend inward from each end of the stock at an angle of about 55deg. to the shank. The latter is provided with chocks or abutments to receive the ends of the pieces, which are held in place laterally by a small pin, passed through the arms and stock, or by a collar or other suitable fastening.—Patent abandoned.

504 F. W. MALLETT, Newhaven, U.S. *Needle machine.* Dated February 18, 1869.

The wires or blanks being cut to the desired length for two needles, are thrown into a hopper, which has in connection with the same a feeding device. This device conveys one blank at a time to the first set of a series of progressive carrying rollers, which take up the blanks in turn and carry them from one to the other; while being so carried by the rollers the needle blanks are stamped, the eyes punched, and the eyes tested by a feeler, which will detect a blank not properly eyed and will stop the feed mechanism for its removal.—Patent abandoned.

505 M. VARY, Scarborough. *Ornamenting surfaces.* Dated February 18, 1869.

The inventor takes a piece of paper, or other suitable material, and coats or prepares it with size, made in any convenient manner, and allows the same to dry. On the surface so prepared he prints, draws, stencils, paints, or otherwise makes any design, device, or character in or of any colour or colours or material required, or he cuts, stamps, or perforates out any design, device, or character, or he partly paints and partly cuts the design or character required. The cutting, stamping, or perforating may be effected either previously to the sizing or subsequently thereto, or subsequently to the printing.—Patent completed.

506 F. DELBREIL, Versailles. *Utilisation of excrement.* Dated February 18, 1869.

The inventor proposes to make use of a locomotive engine suited to run on common roads for the purpose of conveying any convenient number of waggons to the spot at which they are to be loaded with sewage, or other similar matter, and transporting such matter to appointed depots. These waggons should be so constructed as to suit the special service for which they are intended, an enclosed waggon having a body built in the form, for example, of a barrel, would be well adapted for carrying sewage matter in a liquid state.—Patent abandoned.

507 T. FORSTER and P. B. COW, jun., Streatham. *India-rubber pipes.* Dated February 18, 1869.

In manufacturing suction and other pipes the inventors, substitute for the galvanized iron wire coil used in the manufacture of ordinary suction and other hose, alternate rings or spirals of rubber having two different quantities of sulphur in them, so that after the operation of steam vulcanizing every alternate ring or spiral will be hard, while the intermediate ones will be flexible. In manufacturing india-rubber hose, buckets, bags, and such like vessels, the inventors substitute for the cotton or linen fabric ordinarily used for giving strength a material composed of rubber and fibre.—Patent abandoned.

508 W. M. COCHRANE, Surbiton. *Water vessels.* Dated February 19, 1869.

This consists in the use of a bottle or vessel of glass, glazed pottery, or other suitable material (but by preference of ebonite) protected by a covering of felt, or other non-conducting material, which also serves for maintaining the temperature of water or other liquid contained in the bottle or vessel.—Patent completed.

509 T. TUNSTILL and J. DODGEON. *Looms.* Dated February 19, 1869.

The inventors employ ordinary friction pulleys, and chains, belts, or cords, to each end of the beam, and also an ordinary vibrator or shaft, with a vibratory crank bar, which they invert, that is to say, they place the crank underneath or betwixt the shaft and the warp beam, so that the warp will first pass under the crank bar, and thence over the shaft to the healds. The friction chains or cords are each attached to separate levers, each lever being hinged at one end to one of the loom ends respectively. The other ends of the levers projecting towards each other are connected by a T-formed lever, bar, or by chain, belt, or cord and pulley, attached equidistantly from the fulcrums of the lever to a weighted lever hinged at one end to the cross rail of the loom, the other or weighted end of this lever being connected by a chain, belt, or cord to a pulley or lever fixed on the vibrator shaft, so that the pull or stretch of the warp will always lift the weighted lever and release or remove the pressure from the warp beam, and thereby let off the proper quantity of warp required.—Patent abandoned.

510 E. DORSETT, London-street, E.C. *Furnaces.* Dated February 19, 1869.

This consists in the employment of liquid hydrocarbons for the purpose of producing an intense heat in furnaces, chambers, or kilns used for heating, smelting, or working metals and other substances. In carrying out the invention the inventor first evaporates and distributes in the vaporized state under pressure (as described in a patent granted January 18, 1868, No. 176) the liquid hydrocarbons through a pipe or series of pipes, from which the vapour issues in the form of jets. As this vapour escapes from the holes in the pipe it mixes with the air necessary for its combustion (the air being previously heated if required) and the hydrocarbon vapour thus mixed with air (or in some cases with steam or other gases) enters the chamber or furnace through an opening or openings formed therein wherever it may be found most convenient, such openings being provided with doors or other means of regulating the quantity of air or gas required to feed the flame, or to modify its action upon the metal placed in the furnace to be heated, melted, or converted, as the case may be.—Patent completed.

511 A. HENRY, Edinburgh. *Breech loaders.* Dated February 19, 1869.

This consists, in the first place, in arranging the breech-piece, lock, and extractor in such a manner that, on lowering the breechpiece after the discharge of the firearm, the lock is cocked in readiness for the next discharge, and the spent cartridge case extracted. These actions are effected in the following manner:—In the rear end of the breech cavity, an opening is made through which protrudes one end of a bent lever which is carried upon a centre bearing stud or shaft. The lower end of the lever projects downwards behind the breech cavity, and in an opening in the stock wherein the lock is also contained. On depressing the lever to which the sliding breechpiece is connected, the breech being thereby lowered, its under side comes into contact with the projecting end of the lever before referred to, which is therefore depressed, whilst its outer end is elevated, and in being so elevated it comes into contact with a projection attached to the tumbler, which is therefore also raised until it is thrown into "full cocked" or "half cocked" position, in which it is retained by a pawl falling into notches or catches made in the lower edge of the tumbler piece.—Patent completed.

512 L. G. MOORE, Erith. *Windmill feather sails.* Dated February 19, 1869.

The opposite arms are made extending from the extreme end of one sail to the extreme end of the other and opposite sail, thereby having the two sails opposite to each other. On one arm the two sails are fixed at right angles to each other, and the arm is held in such a manner on the axis that it can partly revolve and the sails move with it, so that when one sail is in position to catch the wind the opposite sail coming against the wind is edge-wise, and offers little resistance. The arms are fixed on the sails at a point a little above the centre of gravity, and stops are provided to prevent the arm turning more than required for feathering the sails, which are under the control of a governor worked by the wind.—Patent abandoned.

513 J. LOADER, Finsbury. *Steam generators.* Dated February 19, 1869.

The inventor leads the steam pipe or tube through the main body of the water in the steam generator or boiler.—Patent completed.

514 S. MYERS, New Bond-street. *Churns.* Dated February 19, 1869.

In a cylindrical or otherwise shaped vessel containing the cream, egg yolks, or other matter to be treated, is an axis or shaft free to revolve when turned by hand or otherwise, and communicating motion to a fan wheel or screw, or a contrivance consisting of blades, vanes, or plates, placed in any desirable position with respect to the shaft. For instance, in one arrangement this wheel or fan may consist of segments, sections, or interrupted portions of discs or circular plates, which, if completed (or the planes of which) would intersect each other at right angles or other angle. Two of the vanes may be in a line with, that is to say longitudinally of, the shaft, and two may be at right angles thereto, or they may be at various angles to the shaft and to each other. They may be straight or curved, plane or helical, and they may form portions, segments, or sections of a screw. They may be perforated or not. Rotary motion on being communicated to this shaft or axis transmits such motion to the blades, vanes, or plates mounted in the vessel, and the necessary action is thereby produced on the cream or other substance to be treated in the vessel.—Patent completed.

515 T. SMITH, Manchester. *Treating woollen cloth.* Dated February 19, 1869.

The inventor spreads over the cloth spermaceti, paraffin, or other such matters, either alone or in combination with wax. The arrangement of apparatus employed for applying the material in a cold state, to be subsequently heated, consists of three cylinders made of wire gauze, or otherwise provided with fine perforations; beyond these are steam cylinders such as are ordinarily used for drying woven fabrics, and there are tension rollers as well as a roller upon which the goods to be thickened are placed, and another roller which receives the goods when so treated. The thickening substance having been reduced to a powder, is placed in the first-named cylinders, and the goods are caused by the tension rollers to pass in contact with the surfaces of the gauze cylinders, and subsequently in contact with the steam or second-named cylinders, after which they are wound upon the roller last named.—Patent completed.

516 J. DAVEY, Wisbeach. *Motive power engines.* Dated February 19, 1869.

The inventor causes what may be considered the cylinder head to travel with the piston until it approaches the initial point. It will then rest, and steam being admitted between it and the piston, the piston will be caused to act in the ordinary manner.—Patent abandoned.

517 A. M. CLARK, Chancery-lane. *Increasing tractive power.* Dated February 19, 1869.

This consists in providing a series of flat independent bearing surfaces, each attached at its centre to the periphery of the traction wheel. These flat bearing surfaces are provided with cheeks embracing the rim of the wheel

in the manner of a skid brake, and form horizontal surfaces bearing in succession upon the road in lieu of the circular surface of an ordinary wheel, to which the flat surfaces are tangential.—Patent completed.

518 E. HEWETT, St. Leonard's-on-Sea. *Chimney cowls.* Dated February 19, 1869.

The inventor forms the cowl of a tube of considerable height, and of about the same diameter as the chimney itself, above which it is mounted so as to turn on a vertical pivot. The top of this tube may either be closed and provided with an aperture at one side for the exit of the smoke, or it may be of curved form like an ordinary cowl, and is in each case provided with a suitable vane. The top of the chimney is closed with the exception of a central opening for a smoke tube of about half the diameter of the cowl mounted on the top of the chimney, and passing about half way up the cowl.—Patent completed.

519 H. T. and T. JENNINGS, Sidney-street, City-road. *Steam engines.* Dated February 19, 1869.

In addition to forming the cylinder with two passages leading one to each of its ends, through which steam is alternately admitted to and allowed to escape from the ends of the cylinder by means of a slide valve worked by an eccentric, as heretofore, the inventor also forms another opening at each end of the cylinder, which opening or passage is only employed for allowing steam to escape from the cylinder. The opening and closing of these passages he effects by means of a slide valve worked, by preference, by cams on the crank shaft or by tappets from the piston of the engine, so that as the piston is moving towards one end of the cylinder not only will the ordinary exhaust passage be open to allow steam to escape from that end of the cylinder, but, in addition, there will be a second outlet for the steam, and this second outlet will be kept open until the piston has all but completed its stroke.—Patent completed.

520 J. BARTON, Birkenhead. *Water heater.* Dated February 19, 1869.

This consists in bringing steam into direct contact with the water to be heated in a closed vessel, when the supply of water to such closed vessel is controlled by mechanism operated automatically from or by the water level in the closed vessel or heater.—Patent completed.

521 W. R. LAKE, Southampton-buildings, W.C. *Ice apparatus.* (A communication.) Dated February 19, 1869.

The inventor first constructs a box or case of wood, of which the first thickness is about 8-10in., more or less, according to the size of the box to be made. The interior of this first thickness is furnished with another 1in. and six-tenths or more of some bad conducting material, such as powdered wood charcoal or tan after it has served in the tannery. This bed or thickness is covered with an envelope of wood of slight thickness, so as not to make the apparatus too heavy. This envelope is fixed to the first in such a manner that the non-conducting material or bed cannot escape or be displaced, the sides of the case having altogether a thickness of about 2½in. The whole is covered internally with sheet metal, well soldered at the corners to prevent any communication with the non-conducting bed.—Patent completed.

522 M. M'LENNAN, Liverpool. *Permanent way.* Dated February 19, 1869.

This consists, first, in making the joint sleepers, on which the rails are fixed, of iron, secured at the joints by "monkey plates," and fastened by bolts and nuts in a similar manner to the fish plates now in general use. The rails and sleepers thus become united as one piece throughout, the sleepers being so formed as to keep the rails in gauge. Second, in making the intermediate sleepers of iron on which the rails are fixed by means of bolts, washers, and nuts, sufficient provision being made for expansion and contraction of the rail, and also in forming the sleepers like the joint so as to keep the rails in gauge. —Patent completed.

523 G. G. HAIRS, Little Distaff-lane, E.C. *Burning combustible liquids.* Dated February 20, 1869.

The inventor places over a gas burner a vessel or generator of a double cup-like form, which he sometimes surrounds by a chimney. Petroleum or the combustible liquid to be vaporised is placed in the inner cup, which is closed airtight. Gas is admitted by a pipe to the upper part of the cup-formed generator, and after passing over the surface of the petroleum or other liquid (which, being heated, gives off vapour freely) it passes away to the burner beneath by a pipe descending through the bottoms of the double-cup generator. Other pipes may also be connected with the double cup generator to lead off the gas or vapour to other burners, as may be required.—Patent abandoned.

524 G. GREEN, Aberystwith. *Buddles for separating ores, &c.* Dated February 20, 1869.

The improved apparatus comprises a stationary conical table, with its centre depressed and its outer circular rim in a horizontal plane. A vertical shaft passes up through a central aperture, and is made to revolve slowly by any convenient motive power. A tubular arm is carried by the revolving shaft, and, receiving the ores in a pulverised condition and mixed with some water by a central duct in connection with the shaft, delivers them from its outer end round near the outer edge and upon the higher part of the conical table. The shaft also carries a water pipe, which is furnished with small perforated branches, each with an adjusting cock, the series of branches being disposed in the form of a spiral, the outer end of which is a little behind the end of the arm that delivers the ore.—Patent abandoned.

525 J. D. GAULDIE and T. A. MARSHALL, Glasgow. *Steam engines and boilers.* Dated February 20, 1869.

It is proposed to use high pressure steam in cylinders of comparatively small size and working at a comparatively quick rate, with valve gear which can be varied or adjusted by means of a governor so as to keep the engine at a nearly uniform rate, notwithstanding considerable variations in the load.—Patent abandoned.

526 J. T. WIBBERLEY, Leicester. *Winding apparatus.* Dated February 20, 1869.

On the ordinary sliding shaft which carries the right and left handed nuts, the inventor places an arm extending to the top of the machine, and fixed to a tube which works loose on the ordinary sliding shaft, carrying at each end the right and left handed nuts; he also employs two stays extending through a fixed plate on the top of the machine head, and connected to a slide working in guides or recesses in the fixed plate. On the top of the stays he fixes a plate which supports another movable plate working in recesses and carrying at each side a slide catch spring and adjustable screw, and near each end of the movable plate there is a pin projecting from underneath and working in a slot in the under plate.—Patent abandoned.

527 J. MASSON, Norwood. *Corkscrew and wax receptacle.* Dated February 20, 1869.

This consists in the employment of a lever for lifting the stem or shank of a corkscrew after the ordinary spiral has been inserted into the cork. This lever is hinged to the top of a barrel passed over the bottle neck; one arm of the lever is a curved loop which embraces the stem, and the other arm forms a handle.—Patent completed.

528 A. JACOB, Bromley. *Sewer ventilating.* Dated February 20, 1869.

This consists in purifying the effluvia in their escape to the surface of the ground, and by facilitating the disposal and removal of charcoal or other material having the property of destroying the injurious effects of sewer gases on health by means of manhole covers.—Patent completed.

529 J. EBERHARD, Tolmer-square, Hampstead-road. *Propelling ships.* Dated February 20, 1869.

At that part of the vessel where the propelling blade or blades protrude, a hole is formed or cut, and each hole thus formed is fitted with a movable filling piece hung vertically on pivots. Each movable filling piece is of the external form of a segment of a circle, so that during the portion of the revolution which it is permitted to make, it exactly fits and fills the hole and makes a watertight joint. Each filling piece is also formed with a longitudinal slot of the size of the propelling blade, so that the blade can pass in and out therethrough.—Patent abandoned.

530 H. W. WHITEHEAD, Holbeck. *Wool combing machinery.* Dated February 20, 1869.

This relates to Noble's combing machine. The object of these improvements is to effect the clearing of the fibre from the noil and other impurities, and this is done by causing the teeth of an inverted circular comb, which may be called a noil-intersecting comb, to work between the inner and smaller circular comb and its drawing-off rollers.—Patent completed.

531 M. GRAY, Highbury-hill. *Electrical conductors.* Dated February 20, 1869.

The conducting copper wire or the strands of fine copper slightly twisted to cause them to hold together are enclosed, first, in pure india-rubber in the ordinary way of insulating conducting wires. This insulated core is overlain with a plastic compound of india-rubber and sulphur of any required thickness, the same being applied by means of the machine shown and described in the specification of the patent granted to the present inventor, F. Hawkins, dated August 11, 1868, or any other suitable machinery may be employed for the purpose. The inventor next laps or coils helically around this coating of india-rubber and sulphur compound (while still in a green or uncured state) a tape or strip of cotton or other suitable fibre measuring (say) 1in. (or more or less) in breadth. This cloth covering he pays over with a solution of the rubber compound, and he prepares the face of a second tape or strip of cloth of similar quality and breadth with the like solution. He then laps this coated cloth or tape (the prepared surface inwards) around the coated wire, laying it, however, in the opposite direction to that of the first cloth covering.—Patent completed.

532 J. H. MOEL, Cambridge. *Hair-cutting machines.* Dated February 20, 1869.

The inventor mounts the drum or axis on which helical knives are fixed in spring bearings, so arranged as to allow those knives which are made rotating to recede slightly from the fixed knife when cutting an unusual thickness of hair.—Patent completed.

533 T. H. SIMMONDS, Great Mitchell-street, St. Luke's, and E. B. MORELAND, Bartholomew-close. *Paper collar finishing compound.* Dated February 20, 1869.

The proportions in this compound are as follows:—Starch in solution, about 25 parts; "satin" in solution, about 25 parts; size in solution, about 12½ parts; glue in solution, about 12½ parts. The ingredients, after being reduced to a liquid condition by the addition of a sufficient amount of hot water, are mixed together, and in this condition applied in any suitable manner on the material to be glazed or finished.—Patent abandoned.

534 B. F. WEST, Rochester, New York. *Double jointed butt hinge.* (A communication.) Dated February 20, 1869.

The improved hinge consists of four plates or leaves, two long plates and two short ones. One of the long plates is secured to the door and the other to the post or jamb. The two long plates are each jointed at the opposite sides of each end to one of the short plates, and when the hinge is close the two long plates lie parallel to each other with the short plates between them. The two short plates are placed end to end, and their opposite edges carry the two joint pins of each end of the hinge, each end of the long plates or leaves of the hinge being connected to the joint at opposite edges of the short plates.—Patent abandoned.

535 F. G. FLEURY, Merrick-square, Southwark, *Water meters.* Dated February 20, 1869.

The casing, which is by preference made in three parts or portions, is constructed so as to form four measuring chambers, two of the chambers with a common axis being smaller than the other two chambers, which likewise have a common axis at right angles, however, to the axis of the two smaller measuring chambers. In meters of large size the two large chambers may be provided with covers. Each measuring chamber is provided with a piston fitting accurately within it. The pistons of the larger measuring chambers are both secured to one flat piston rod, one of the pistons being situated at each end of the rod, the pistons of the two smaller measuring chambers are secured one to each end of a bar (by preference slotted) or to a frame.—Patent completed.

536 J DAGLISH, Seaham Harbour. *Ventilating of mines.* Dated February 20, 1869.

The inventor places the ventilator near the bottom of the upcast shaft, and he arranges it so as to exhaust the air from the workings and force it up the upcast shaft, or he places the ventilator at the bottom of the downcast shaft and arranges it to draw the air down this shaft and force it through the workings and thence up the upcast shaft, thereby causing a constant current of air to move down the one shaft, through the workings, and up the other shaft.—Patent abandoned.

537 R. FOSTER, Buxton, Nottinghamshire. *Boilers.* Dated February 20, 1869.

Upon brickwork is a number of firebars, and upon this brickwork are secured a number of metal bearers upon which stand three separate hollow castings. Two of these castings are placed parallel with the firebars and stand upon the bearers, one of their ends being placed close to the casting or framing to which the furnace door is hung. This frame or casting has a door to close the front of the ashpit below the firebars. The other ends of the two parallel castings lie close to one side of a third casting, which forms the back and has its top side somewhat higher than the tops of the two parallel castings.—Patent abandoned.

538 J. E. LUCAS, Allhallows-chambers, E.C. *Floating velocipede.* (A communication.) Dated February 20, 1869.

This consists in obtaining the requisite buoyancy in a velocipede for navigating the water by means of the propelling wheels and rudder. For this purpose the rudder and wheels are each constructed with one or more airtight chambers or compartments.—Patent completed.

539 J. and W. WEEMS, Johnstone, Renfrewshire. *Malting, heating, and drying apparatus.* Dated February 22, 1869.

This consists in having a series of discs or floors arranged one above the other, and passing through the centre of these floors is an upright revolving shaft with radial arms, on which are fixed directing blades or conveyers. These floors have openings at their centre and periphery for the passage of the grain from floor to floor. The barley or malt being fed on to the top floor at the centre is distributed over it in layers by the directing blades, and descending on to the next floor at the outer openings passes from thence to the centre, and falling through the central opening and so on until by the action of the blades all the floors are covered.—Patent completed.

540 W. IBOTSON, New Inn, Strand, W. W. LADELLE, Wraysbury, and A. G. SOUTHBY, Bulford House, near Amesbury. *Paper manufacture.* Dated February 22, 1869.

The inventors feed the materials, in order to secure regularity, either by hand or by a revolving roller or rollers, or other apparatus into one end of a revolving cylinder, and at the same time feed into the other end water or such chemical solutions as may be desirable (the same being either hot or cold) and make the materials pass through in one direction while the water or other solutions pass through in the other, the two being alternately beaten and rubbed together and squeezed apart during their passage by the action of rollers and strainers, or of either of them.—Patent completed.

541 S. OSBORN, Sheffield. *Reaping and mowing knives.* Dated February 22, 1869.

This consists in making the knife bar in the form of a clip by folding a long strip of malleable iron or steel or other suitable metal along a longitudinal line. If preferred, the clip may be folded along a line more or less on one side of the centre line, so that one edge may project beyond the other. The folding of the strip of metal may be effected in any convenient manner, but it is preferred to first bend or partially fold it between a pair of dies in a suitable press, the upper die being a narrow angular piece, which bears upon the longitudinal centre line of the strip or bar, whilst the lower die is in the form of a groove with inclined sides. The strip or bar being suitably heated is laid upon the grooved die and is forced and bent down into the groove by the descent of the upper die. The partially folded strip is then reheated and is placed between a pair of flat-faced dies, which compress the two edges of the strip together. The faces of the second die are slightly inclined towards each other, and they compress the edges of the strip together, whilst leaving the inner parts of the recess or grooves at a distant apart corresponding to the thickness of knife to be inserted. —Patent completed.

542 J. O. C. PHILLIPS, Birmingham. *Artificial teeth.* Dated February 22, 1869.

This consists in setting each tooth in an elastic socket, by means of which the teeth are connected either directly or indirectly to the artificial gums.—Patent completed.

543 J. W. REID, Bayswater. *Paper pulp apparatus.* Dated February 22, 1869.

This consists chiefly in subjecting the wood or other vegetable fibres to the action of heat and alkali, and at the same time projecting them during the whole process, by keeping them covered by the liquor from the deleterious action of the steam necessarily generated by the heat.—Patent completed.

544 W. R. LAKE, Southampton-buildings. "*Locomotive heating.*" (A communication.) Dated February 22, 1869.

The apparatus consists of a vessel fixed to the fire-box, which serves as a reservoir for the coal. This reservoir is filled from the tender through a tube. The reservoir is closed at the top by a conical cover to prevent the falling in of the ashes from the grate bars; the ashes fall upon the cover, and from the cover pass to the ashpit.—Patent completed.

545 G. A. FALL, Hoboken. *Propelling vessels.* Dated February 22, 1869.

The object is to avoid the friction of a vessel sliding endwise through the water. This is accomplished by making the buoyant power a series of revolving cylindrical floats, arranged in pairs on shafts so as to roll over the water and sustain a platform between four or more such floats, or these floats may be arranged one behind the other.—Patent completed.

546 T. S. BLAIR, Pittsburg, U.S. *Iron and steel.* Dated February 22, 1869.

This relates to a previous patent dated November 23, 1868, No. 3565. The inventor now employs manganese, and takes any of the various oxides of that metal according to economic advantage, and reduces the one chosen to about the same degree of fineness to which the iron or other oxide has been reduced that is to be employed in the manufacture of the conglomerate or "pig bloom" by the process. It may be in the form of powder, but as it is important that it should be well and evenly mixed through the ore, it will be found desirable to have the two materials of about an equal degree of fineness.—Patent abandoned.

547 J. and T. LEACH, and J. GOODYEAR. *Wool winding.* Dated February 22, 1869.

In guides at the upper part of two side frames, the inventors place slides carrying discs forming the flanges of the bobbin, there being a central hole in one of the discs for the bobbin to pass through and a central hole in the other disc for a pin which passes through a hole in the centre of the bobbin. In one of the slides is formed a

seating of the same radius as the bobbin and central with it, and in the other slide there is a central hole corresponding with the hole in the disc for the bearing pin to pass through. Below the slides there is a shaft carrying a toothed wheel or pulley for working the machine. A surface drum for causing the bobbin and lap to revolve, and a pinion for giving motion by means of the gearing to a wheel, are placed at an angle for working the traversing lever. On the shaft is also fixed a ratchet and a loose cam having at one side a catch, and arm, and lappets, the catch gearing with the ratchet wheel when revolving motion is required to be given to the cam and lappets for working a lever and plate used for pushing off the bobbin and lap when the winding on is completed and to prevent the catch gearing with the ratchet wheel. Until required, the arm of the catch is held back by a finger on the front slide.—Patent completed.

548 B. J. B. MILLS, Southampton-buildings. *Artificial stone.* (A communication.) Dated February 22, 1869.

This consists in the production of an artificial stone by combining fragments, chips, or powder of stone or other mineral substance with calcined magnesia and bittern water.—Patent abandoned.

549 J. E. LILLER, Bedford. *Apparatus for printing.* Dated February 22, 1869.

This consists in the employment of a band which is made to travel so as to present to the face of the "form" one of its surfaces and to withdraw it again at required intervals. The sheets of paper or other material are placed on the surface of the band which is so presented and withdrawn, and are thus carried to and from the required position.—Patent completed.

550 J. H. JOHNSON, Lincoln's Inn-fields. *Velocipedes.* (A communication.) Dated February 22, 1869.

A wheel is employed in which is a circular opening concentric with the periphery of the wheel, and in this opening is an annular rib on each side of which a flange of a driving wheel fits snugly, but so as to move freely, the peripheries only of the two flanges of the driving wheel bearing against the inside of the annular opening in the main wheel. The driving wheel is secured to a spindle which passes through and has its bearing in the opposite sides of a seat or saddle at one end of the same, the opposite end of the saddle having a spring carrying a flanged roller adapted to the circular rib of the main wheel.—Patent abandoned.

551 W. E. NEWTON, Chancery-lane. *Screw wrenches.* (A communication.) Dated February 22, 1869.

This consists, first, in constructing the hole through the sliding jaw for the shank to pass through sufficiently large to admit of the jaw being readily disengaged from the screw, or be thrown into gear therewith so that the adjustment of the jaw on or along the shank may be effected either by an independent sliding movement of the jaw along the shank or by or through the intervention of the screw, at the pleasure of the operator, and as circumstances require.—Patent abandoned.

552 J. B. RUSHBROOK, Bury St. Edmunds. *Sheep fold hurdles.* Dated February 22, 1869.

This consists in constructing an iron hurdle with two openings capable of being adjusted wider or narrower at will to suit the size of the lambs and sheep that have to pass through them. Another feature of novelty consists in providing the top and sides of such openings with rollers to prevent injury to the lambs, and also to enable them to pass freely through the said openings. It is proposed to use one of these hurdles at each side of the pen or fold, and to connect wooden hurdles of the ordinary kind with the metal hurdles above mentioned in the construction of the fold.—Patent abandoned.

553 R. MELDRUM, Pittormie, Cupar. *Stopping locomotives.* Dated February 22, 1869.

This consists in making communication from the steam boiler, air, gas, or water chamber, directly to or about that part of the cylinder whence the steam, air, gas, or water escapes after having done its work in the cylinder. —Patent abandoned.

554 J. BLYDE, Sheffield. *Gardeners' scissors.* Dated February 22, 1869.

The inventor affixes a spring to one of the blades of the scissors or apparatus, which spring is secured to a piece or holder situate at the side of that one of the blades above referred to, such piece extending beyond the edge of the same and having a broad part which acts against the other blade of the scissors or apparatus, by which arrangements the desired action of the scissors will be obtained.—Patent abandoned.

555 H. F. FREUTEL, Kingsland-road. *Hats and caps.* Dated January 22, 1869.

The inventor proposes, instead of applying a lining or body of cork, gossamer, hair, or other usual fabric, to employ a body or lining of paper, which is to be caused to adhere to the outer fabric or covering by means of a solution of caoutchouc, gutta percha, shellac, or other suitable adhesive solution or any combination of the same.—Patent abandoned.

556 R. P. WILLIAMS, Great George-street, S.W. *Railway crossings and switches.* Dated February 22, 1869.

In constructing railway crossings where two lines cross each other, the inventor forms one of the crossing lines of a continuous rail and the other crossing line in two parts, one on each side of the continuous rail. Each part where it meets the continuous rail is bent round at an angle to come parallel with this rail, and is securely fixed thereto. The bent round end of the rail which comes up to the inner side of the continuous rail is retained at the requisite distance from it to allow of its bent round end serving as a guard rail. The continuous rail and the bent end of one of the parts of the crossing rail are notched out to the requisite depth, for the rail which forms the guard rail is thus notched, but in the case of an acute crossing, then the bent end of the other rail is notched out.—Patent completed.

557 J. T. GAZE and J. HYMAS, Erith, Kent. *Grate bars.* Dated February 23, 1869.

The inventors cast or form the grate bars together in sections or groups of three, by preference with spaces between for the admission of air, so that they form three ribs connected at intervals by narrow strips.—Patent abandoned.

558 A. JOBSON, Darlington. *Coke ovens.* Dated February 23, 1869.

The coke ovens are built on pillars of firebrick or stone in such a manner as to allow of space beneath them for the application of an improved system of unloading or discharging them, and no door is formed in front of the oven. The bottom, instead of being constructed in the ordinary manner, is formed either wholly or principally of a movable bottom or door, opened and closed and supported when shut by means of toothed arcs or segments. The framework of the door is of iron, which may be cast, but it is preferred that it should be malleable iron, the bottom part being one piece of plate secured to the surrounding angle iron in such a manner as to bind the whole securely together, and to exclude the air as far as practicable. On the plate iron are supported fireclay quarries of suitable thickness, bedded in ground fireclay to protect the iron from the action of the fire, and to maintain the lower part of the coke oven as hot as possible. To still further prevent the radiation of heat a stratum of any non-conducting substance may be interposed between the fireclay quarries and the bottom iron plate.—Patent completed.

559 J. BREEDEN, Birmingham. *Taps and stopcocks.* Dated February 23, 1869.

The body of the tap is made in two halves or parts joined together by flanges, the body having internally the general figure of a hollow cylinder. The entrance pipe opens into the lower half or part, and the exit pipe into the upper half or part of the body. A circular disc of strong and hard leather is inserted and fixed between the flanges of the two parts of the body of the tap, the disc constituting a diaphragm extending across the middle of the said body. This diaphragm has one or more perforations in it through which the liquid or fluid passes, and on the lower side of the diaphragm is fixed a metal strengthening plate having an opening in it coincident with that in the diaphragm. In the upper half of the body is a plug, the lower portion of which is of the same diameter as the body, and works closely but freely therein. The upper end or stem of the plug passes out at the top of the tap, and is provided with a handle or with a lever for giving a rotary motion to the plug. The lower end of the plug bears upon the upper side of the leather diaphragm, and has a hole in it similar in size, shape, and position to that in the diaphragm.—Patent completed.

560 J. JOHNSON and W. GILL, Unstone, Derby. *Rotary engines and pumps.* Dated February 23, 1869.

This consists of a cylinder secured on a foundation, and having a central shaft working in bearings at each end or side of the cylinder. On this shaft is mounted a circular piston revolving eccentrically around and within the cylinder, at the top of which the inlet and exhaust pipes are applied.—Patent completed.

561 B. W. FAREY, Bermondsey. *Gas valve facings.* Dated February 23, 1869.

A groove is formed in one or both of the seatings or faces of the valve, into which groove is introduced, by any suitable means, water, oil, or other fluids, which must be at a pressure exceeding that of the gas for which the valve is employed to regulate or stop the flow. It will be readily understood that should the seatings or faces of the valve not be tight, a leakage of water, oil, or other fluid will take place, thus effectually preventing all escape of gas between the seatings or faces. Any water, or oil, or other fluid so leaking through can be taken off by syphons, one on each side of the diaphragm or slide of the valve, or by any other convenient method.—Patent completed.

562 W. F. C. MOUTRIE, Southampton-row. *Pianofortes.* Dated February 23, 1869.

This consists in the addition of one or more strings to the scale of the ordinary pianoforte now in use, when by means of any convenient mechanical arrangement the player can at will alter the pitch from that in ordinary use to a lower one, or if he should desire it to a higher one.—Patent abandoned.

563 J. NEILSON and J. MARSHALL, Glasgow. *Metallic capsules.* Dated February 23, 1869.

This consists in coating the end or other part of the metallic capsule with varnish or resin, in pressing thereon paper which has had the trade mark, name, or device printed on it on the face or side that is applied to the capsule, in washing away the paper, and in finally protecting the trade mark, name, or device which remains on the capsule with a thin coating of glue or varnish.—Patent completed.

564 A. V. NEWTON, Chancery-lane. *Locomotive fireboxes and ashpans.* (A communication.) Dated February 23, 1869.

This relates, first, to the use in locomotive engines of fireboxes with solid or pan-like bottoms (that is, without grate bars or openings through the bottoms), whereby the live coal will be retained in the firebox until wholly consumed, and any scattering of coals or fire upon the track will be prevented. Second, to the arranging of the draught flues and dampers so that the air will pass over the firepan or ashpan and feed the fire from the four sides of the furnace, and at a convenient distance above the bottom of the pan, which arrangement secures a very effective feed or supply of the air to the fire. Third, to a combination of angle plates with a firebox having a close or solid bottom, whereby the fuel is made to slide down and press together in close contact as it is being consumed.—Patent completed.

565 S. HOLROYD, Newton Heath, Manchester. *Recovery of water from gas purification.* Dated February 23, 1869.

The inventor takes the substance which is commonly employed for abstracting sulphur from the gas (oxide of iron, for instance), and places it within a suitable vessel, to which steam or air is admitted, and the temperature thereof being raised, the sulphur is detached from the iron and may be recovered for the manufacture of sulphuric acid or other ordinary purposes.—Patent abandoned.

566 H. BESSEMER, Queen's-street Place, Cannon-street. *Making cast from pig iron.* Dated February 23, 1869.

The inventor prefers to place two or more converting vessels in such a position with reference to each other that their respective axes are in a straight line with the axes, being at a distance of 3ft. to 4ft. above the general floor level. Beneath each vessel a small pit is formed, and an arched passage passes from one pit to the other in the line of the vessels' axes, and terminating beyond the building, so that, by means of a line of rails laid in the passage, the ashes or other debris of the operation may be readily removed on trucks moving on three rails. An incline or a lift may be employed to raise the trucks up to the general ground level.—Patent completed.

567 W. E. GEDGE, Wellington-street, Strand. *Hand vice.* (A communication.) Dated February 24, 1869.

The horizontal screw of ordinary hand vices is in this invention replaced by a vertical pressure or adjusting screw, which is pierced in its entire length, as is also the handle to facilitate working upon a long rod or spindle, on which it is desired to cut a screw or make a long pin.—Patent completed.

568 J. J. MYERS, Spa-road. *Railway warnings.* Dated February 24, 1869.

Inside and longitudinally with the ceiling of each carriage, the inventor uses a cord, rope, or chain, connected with a screw and nut or hook and eye in each compartment, so as to form a continuous line capable of being disconnected at will in each division of the carriage. One end of this cord, rope, or chain is fastened inside to one end of the carriage, and the other end is connected with a weighted lever (with or without a spring) fixed and working a movable shaft or spindle in suitable bearings on brackets projecting from and fixed to one end of each carriage outside. The shaft or spindle at one of its ends has a projection at a right angle similar to a half crank or fork, with or without a wheel or roller to diminish friction connected thereto; the under side of the cranked part or fork is bevelled sharply off to form a steep incline. —Patent abandoned.

569 J. WHITEHEAD, Oldham. *Furnaces.* Dated February 24, 1869.

This consists, principally, in the application of a perforated block of brickwork or fireclay of any length, which is placed above or in the place of the ordinary bridge at the back end of the firebars. This block of brickwork or fireclay rises from the level of the firebars up to the top of the flue in fluid bodies, and up to the boiler in fireplaces for egg-ended or any other kind of boilers which are fixed underneath.—Patent abandoned.

570 W. A. IVES, New Haven, Connecticut, U.S. *Tenon and mortise machines.* Dated February 24, 1869.

This consists of a table on which is laid the woods to be tenoned and mortised. This table has appropriate machinery for imparting to the wood intermittent reciprocating movements back and forth, as well as laterally, like a planing machine, for the purpose of feeding the wood up to a mortising expansive bit and tenoning hollow expansive auger, which are held in position by a tool holder and holders being sustained in bearings on the stand, and having toothed wheels on their inner ends which engage with a wheel on the driving shaft carrying a pulley and belt through which the combination is operated.—Patent completed.

571 W. WILLIAMS, Liverpool. *Pipe joint.* Dated February 24, 1869.

This joint is designed to avoid the defects found in rigid and flexible joints as at present formed. It consists in the direct contact or union of a cylindrical socketed tube with a spherical butt-ended pipe without the intervention or use of lead or packing.—Patent completed.

572 J. COOKE and C. HIBBERT, Richmond. *Steam jet vacuum power.* Dated February 24, 1869.

In applying this invention to a steam engine the inventors connect the exhaust pipe from the steam cylinder to a vessel into which water flows or is injected, and a jet of steam is caused to act on the water as it is passing to the discharge pipe. The nozzle of the steam pipe is tapered off and fits into an enlarged portion of the discharge pipe, the action of the steam inducing a powerful current which draws the air and water from the steam cylinder and produces the desired vacuum therein.—Patent abandoned.

573 B. HUNT, Serle-street, W.C. *Bobbin friction regulators.* (A communication.) Dated February 24, 1869.

The object of this invention is to remedy this defect by rendering automatic the displacement of the small friction cords above mentioned, which may be effected in the following manner:—First, by making the notched bar over which the cords pass advance longitudinally and thus increase the contact of the cords with the bobbins. In this case the points of attachment of the friction cords to the bobbin rail remain fixed. Secondly, by leaving the notched bar a fixture, and causing a bar which carries all the points of attachment of the friction cords to travel longitudinally.—Patent completed.

574 J. I. VAUGHAN, Keusal Green. *Utilising waste liquors from tin plate works.* Dated February 24, 1869.

A quantity of crude magnesite is broken or pulverised and placed in a receptacle containing a liquor containing copperas or sulphate of iron, which is allowed to filter through it, by which means the free sulphuric acid is neutralised. The filtrate is then heated with a further quantity of pulverised magnesite and subjected to heat, whereby the sulphuric acid of the copperas or sulphate of iron contained in the liquor is expelled therefrom and absorbed by the magnesia, the iron being left in the form of oxide. This process may be varied by treating the filtrate with calcined magnesite or magnesia so as to throw down the iron, the supernatant liquor being cleansed and boiled down and the precipitated oxide of iron treated as may be required by drying or roasting to render it applicable for polishing, the manufacture of colours, and other useful purposes.—Patent completed.

575 R. MORTON, Nine Elms. *Gas apparatus.* Dated February 24, 1869.

This consists in casting the mouthpiece somewhat thicker than usual at its outer extremity so as to form a surface about an inch wide all round. The face of the mouthpiece is then turned, planed, and scraped, or otherwise surfaced. The lid may be made of cast malleable iron or steel or other suitable metal, but it is preferred to make it of wrought-iron plate, stamped, shaped, or fashioned into a concavo-convex form with its edge bent up all round its periphery.—Patent completed.

576 G. REES, Holloway. *Designing on glass, &c.* Dated February 24, 1869.

The object is to produce ornaments or devices by vitrifying pounded glass upon glass and glazed ware or by cementing together fragments of coloured glass or glazed ware arranged in patterns or not by vitrifying a layer of pounded glass on to and amongst such fragments. The glass after it is pounded is sifted through sieves, the meshes of which correspond to the size of the particles of glass intended to be used on the surface of the gloss or glazed ware. By way of example, the inventor takes a sheet of glass, whether polished or not, and prepares the surface by brushing or otherwise applying a gummy or other adhesive liquid thereon. He then sprinkles pounded glass over the gum, which adheres to it. The glass thus pre-

pared is placed in a furnace or under heat in any suitable manner in order to vitrify the pounded glass upon the surface of the sheet glass. The pounded glass may be of one or a mixture of colours, or the sheet glass may be of a white or other colour.—Patent completed.

577 J. T. Griffin, Fleet-street. *Harvesting machines.* Dated February 24, 1869.

The finger beam and cutters are connected to bars or supports which pass through one of the main driving wheels, which is supported upon rollers attached by bars to the main axle. The main axle is rigidly fixed to the frame. The driving wheels are each made with an internal rib or feather, the collars bearing upon or against the rib of one of the wheels. The insides of the rim of the wheels are formed with teeth for pinions to work in which drive or operate the cutters. The bars or supports for the finger beam are jointed to the main frame so that they can be raised and lowered by means of a chain and lever placed within reach of the driver in order to regulate the height of cut, the lever being held in place by a bolt passed into holes in a quadrant. The axle in which the pinions are mounted is furnished with two clutches, the forks of which are connected to one hand lever so that both can be thrown into and out of gear simultaneously.—Patent completed.

578 W. H. Tooth, Greenwich. *Manufacture of bricks.* Dated February 24, 1869.

This relates to an improved composition of which bricks, tiles, and the other articles required in building operations may be made. The base of the composition, as in most concrete masses used for similar purposes, is gravel, broken stone, or other hard material, preferring such materials as contain a proportion of iron. The mass is wetted with a solution of soda or other alkali together with a small quantity of sal ammoniac. The addition of a little sulphur in powder will quicken the setting of the ingredients, as it will act on the iron and will develop heat. When well mixed the ingredients may be moulded and pressed in the machine, which also forms the part of this invention, but which it is impossible to describe here. —Patent abandoned.

579 E. A. V. Leroi, Paris. *Carding engines.* Dated February 25, 1869.

This consists, first, in producing, by means of ordinary cards or carding apparatus, madding pieces and slivers of horse or other hair of a description similar to those produced from cotton. Second, in obtaining on the card or carding apparatus products of various textile materials laid one upon the other.—Patent abandoned.

APPLICATIONS FOR LETTERS PATENT.

Dated September 7, 1869.

2627 R. Martyn, Clinton Villa, Redruth, Cornwall, W. W. Martyn, Pennance Gwennap, Cornwall, and W. C. Trevena and T. H. Harry, South Downs, Redruth, Cornwall. A wheel buddle for dressing tin ores, and ores of all metals and water, with ore in suspension and earthy substances.

2628 W. B. Thompson, Dundee. Improvements in auxiliary screw propellers.

2629 W. H. Richards, Birmingham. Improvements in chair and trunk nails, which nails are employed also for other useful and ornamental purposes.

2630 S. Rawsthorne and J. Metcalf, Preston, Lancashire. Improvements in mules for spinning.

2631 A. M. Clark, Chancery-lane. Improvements in the construction of ships and other vessels.

2632 F. Ellershausen, Southampton-buildings, Chancery-lane. Improvements in the means and apparatus for utilising the force of the waves.

2633 T. King, Manchester. Improvements in pianofortes.

2634 G. Little, Rutherford Park, New Jersey, U.S.A. Improvements in apparatus for composing, transmitting, and receiving telegraphic communications.

2635 A. V. Newton, Chancery-lane. An improved mode of preventing the radiation of heat from steam boilers.

Dated September 8, 1869.

2636 R. E. Hodges, Southampton-row, Middlesex. Improvements in keyhole guides.

2637 R. H. Hill, Parliament-street, Westminster. Improvements in crossings for railways.

2638 H. D. P. Cunningham, Bury, near Gosport, Hants. Improvements in means for lifting up and taking off heavy bodies on and from racks or stands or carriages, and in the construction of such stands or racks.

2639 H. B. Barlow, Manchester. An improved knitting machine.

2640 S. Oddy, Adelphi Iron Works, Salford, Manchester, and R. Nuttall, Bury, Lancashire. Improvements in mules for spinning.

2641 C. P. Stewart and J. Kershaw, Atlas Works, Manchester. Improvements in centre rail locomotives.

2642 K. Kraus, Sidmouth-street, Middlesex. An improved watch protector.

2643 T. Walker, Robert-street, Chelsea, Middlesex. Improvements in electro-telegraphy.

2644 C. H. Murray, Loman-street, Southwark. Improvements in the manufacture of screw propellers.

2645 W. E. Newton, Chancery-lane. Improvements in metallic packing for piston rods and other purposes.

2646 A. M. Clark, Chancery-lane. An improved machine for cutting or dressing millstones.

2647 A. and G. E. Earnshaw, Sheffield, and F. Earnshaw, Harrington-street, Middlesex. A new or improved mode of, and apparatus for, comparing musical keys, and for examining and explaining musical relations and harmonies, chords, and consonances.

2648 J. A. Muller, Chancery-lane. Improvements in apparatus for measuring and registering the flow of water and other liquids, part of which improvements is applicable to measuring and registering the flow of gases.

2649 W. Baines, Railway Plant Works, Soho, Smethwick, Staffordshire. Improvements in apparatus for ensuring safety to railway trains by controlling the signals and switches, and by disconnecting and stopping the carriages when requisite to avoid accident.

Dated September 9, 1869.

2650 W. Palliser, Army and Navy Club, Pall Mall. Improvements in rails for railways.

2651 D. J. Williams, Birmingham. Improvements in movable partitions for the interiors of buildings, and in shutters for such wide openings in the outside walls of buildings as require no glass or like substance.

2652 F. Forder and J. J. Traves, Wolverhampton. Improvements in the bearings of loose axles for velocipedes and other carriages.

2653 J. Gillies, Glasgow. Improvements in bushes or shields for the bungholes of casks or other vessels, and in the means employed for fixing the same therein.

2654 A. H. Gilmore, Edinburgh. Improvements in means for protecting or shielding wounds, cutaneous injuries, and sores.

2655 H. A. Bonneville, Sackville-street, Piccadilly. Improvements in electric batteries.

2656 W. T. Lillicrap, Stonehouse, Devonshire. Certain improvements in carts and other vehicles, and in apparatus connected therewith.

2657 J. A. Jaques and J. A. Fanshawe, Tottenham, Middlesex, and J. T. Oakley, Grange-road, Bermondsey, Surrey. Improvements in machinery for grinding and surfacing rings, plates, discs, and other analogous articles.

2658 D. Colville, Red Lion Court, Fleet-street, City. An improved mode of, and apparatus for, producing printing surfaces.

Dated September 10, 1869.

2659 A. H. Brandon, Rue Gaillon, Paris. Improvements in central-fire cartridges for breech-loading firearms.

2660 P. Hall, Birkenhead, Chester. Improvements in apparatus for transmitting motive power.

2661 W. Morris, Whitechapel, Middlesex. A new and improved method of, and apparatus or appliances for, the manufacture of cigars.

2662 W. N. Nicholson, Newark-upon-Trent, Nottinghamshire, and G. Black, Grantham, Lincolnshire. Improvements in agricultural drills for sowing grain and seeds with or without manure, and also for sowing or distributing manure.

2663 J. H. Johnson, Lincoln's Inn-fields. An improved fastening for metallic hoops or bands.

Dated September 11, 1869.

2664 W. R. Lake, Southampton-buildings, Chancery-lane. Improvements in apparatus for extinguishing fires.

2665 L. Henrion, San Pier d'Arena, Italy. An improved mode of, and arrangements for, promoting combustion in fireplaces and furnaces.

2666 S. Simpson, Preston, Lancashire. Improvements in machinery for drawing fine wire.

2667 B. Kershaw, Warwick-place, Maida Hill, Middlesex. Improvements in the construction of vessels or apparatus for preserving meat and other articles of food.

2668 J. E. Moorhead and W. Dudgeon, Donacloney, Ireland. Certain improvements in jacquard machines.

2669 J. H. Johnson, Lincoln's Inn-fields. Improvements in apparatus for producing sonorous signals and musical sounds.

2670 J. G. Tongue, Southampton-buildings, Chancery-lane. Improvements in machinery or apparatus for moulding articles in ceramic or plastic materials.

2671 W. A. Lyttle, The Grove, Hammersmith, Middlesex. Improvements in telegraph posts.

2672 M. Andrew, Birmingham. Improvements in locks and latches.

2673 J. Betteley, Cavendish House, Bootle, Lancashire. Improvements in constructing and sheathing ships.

2674 S. Fox, Stocksbridge Works, Deepcar, near Sheffield. Improvements in the permanent way of railways.

2675 J. B. Palmer, Palace Works, Old Ford-road, Bow, Middlesex. Improvements in the manufacture of matches and fusees, and of surfaces to be used for igniting matches and fusees.

Dated September 13, 1869.

2676 F. S. Cocker, Kingsland, Middlesex. Improvements in velocipedes.

2677 W. E. Gedge, Wellington-street, Strand. An apparatus termed The Indispensable for preventing liquids in ebullition from boiling over.

2678 A. V. Newton, Chancery-lane. Improved means for extinguishing fires and watering streets.

2679 C. Burke, Upper Distillery, Bandon, Cork. Improvements in the treatment of fatty and oily matters to prepare them for the manufacture of candles and for other purposes, and in apparatus for such treatment.

NOTICES OF INTENTION TO PROCEED WITH PATENTS.

From the "London Gazette," September 14, 1869.

1344 W. B. Robins	1458 P. W. Flower, H. Nash, and R. Heathfield
1346 J. P. Balm and R. Newton	1529 W. Naylor
1353 P. Barry	1549 W. M'Adam
1355 S. H. Hodges	1560 A. A. Rossignol
1357 J. B. Nimmo	1563 M. Jarvis and E. Millward
1359 D. P. Wright and C. Butler	1656 A. Homingwey
1364 C. Topham	1781 H. W. Hammond
1366 T. Cockroft	1883 S. Holmes
1370 W. E. Gedge	1944 J. Lomax
1386 J. E. Phillips	1960 W. Cowan
1389 E. N. Hudson	2259 T. Winter
1402 R. Fennelly	2333 F. C. Colney
1403 D. and A. Posener	2425 J. Lewis
1405 J. Ramsbottom and T. M. Pearce	2443 J. G. Dale and E. Milner
1410 W. Henderson	2457 R. F. Fairlie
1419 H. A. Dufrene	2486 W. R. Lake
1422 R. Blezard	2490 W. Byrne
1425 R. F. Hoppe	2507 T. Whitehead
1440 W. R. Lake	2527 T. Coley
1445 J. B. Payne	2537 W. R. Lake
1454 J. B. Handyside	2544 B. Hunt
1456 H. Robinson	2556 J. Holdsworth
1493 L. A. V. Dubourg	
1511 W. R. Lake	

The full titles of the patents in the above list can be ascertained by referring back to their numbers in the list of provisional protections previously published.

Opposition can be entered to the granting of a patent to any of the parties in the above list, who have given notice of their intention to proceed within twenty-one days from the date of the "Gazette" in which the notice appears, by leaving at the Commissioners' office, particulars in writing of the objection to the application.

PATENTS ON WHICH THE STAMP DUTY OF £50 HAS BEEN PAID.

2374 B. Bayliss	2388 G. T. Bousfield
2375 C. C. Connor	2430 A. V. Newton

PATENTS ON WHICH THE STAMP DUTY OF £100 HAS BEEN PAID.

2481 W. Hirst	2514 J. R. Johnson and J. S. Atkinson
2506 W. Richards	2520 G. Bedson
2509 T. Molluenx	

LIST OF SEALED PATENTS.

Sealed September 10, 1869.

741 J. B. Bernier	805 W. and C. S. Catt
754 H. Ormson	1231 W. Robinson
766 G. Bray	1846 J. Tangye
784 J. Tenwick	2166 J. H. Johnson
795 W. R. Lake	

Sealed September 14, 1869.

798 W. M'Adam and S. Schuman	1032 J. Sterriker

Notice.—Having received communications from persons residing in the country to the effect that difficulties are occasionally experienced by them in obtaining copies of printed specification from the Patent Office, in consequence of the varying nature of the postage thereon, our readers are informed that upon receipt from them of particulars of the specifications they require, together with a remittance for the cost and approximate postage thereof, we shall be happy to procure and forward such specifications free of all further charge. Sums under Five Shillings may be remitted in postage stamps, for sums above that amount a Post Office Money Order should be sent, payable to Robertson, Brooman, and Co., Patent Department, 166, Fleet-street, London, E.C., to whom all communications upon the subject should be addressed.

THE

MECHANICS' MAGAZINE.

LONDON: FRIDAY, SEPTEMBER 24, 1869.

ASPHALTED SURFACES.

A MIXTURE of the ordinary coal gas tar and common gravel constitutes nine-tenths of the so-called asphalte, and it is no wonder, when the spurious article is passed off for the genuine, that the latter suffers in the estimation of the public, and many refuse to believe in the durability and efficiency of an asphalted surface. This is the natural result of the very cheap and very bad footpaths and platforms that have been laid down in numerous localities and composed of the ingredients referred to. A surface thus constructed will, in spite of the imperfect nature of its components, if the formation of it be carefully attended to, exist for a time in a smooth and apparently sound condition. This appearance is, however, deceptive. The influence of wear and tear, combined with the action of wet, speedily produces hollows and irregularities, cracks and crevices extend their ramifications in every direction, and the opposite effects of heat and cold are equally active in the work of disintegration and destruction. The one renders it sticky in summer, and the other brittle in winter; the whole mass soon breaks up and has to be removed, to the loss and disgust of those who laid it down, and who register a vow never to employ "asphalte" again for any purpose whatever. If we now consider the difference between the spurious and genuine articles, it will not be surprising that the former has no claims to the title that belongs properly to the latter. Instead of being the hasty result of a mixture of tar and sand or gravel, the genuine asphalte has a very different composition. Its chief ingredient is derived from a natural production, drawn from foreign quarries, or mines as they are generally termed. At present, there are very few of these mines, of which the best known is probably that of Pyrimont. The raw material arrives in the form of dark-coloured amorphous lumps containing a large proportion of bitumen, which is extracted by the employment of suitable mechanical means. One of the principal components of bitumen, according to the nomenclature of M. Boisingault, is the substance asphaltene. It has a chemical composition represented by the formula $C_{20}H_{16}O_3$, and we recommend it to those whom it may concern as an excellent name whereby to distinguish the genuine from the spurious article. When it is kept in view that, in order to obtain a material fit for manufacturing asphalte as it ought to be made, it is necessary to import the chief ingredient from Italy, it is evident at a glance that there will be a wide difference in the price of the foreign and the home production. As the price, so is the quality. A permanency and durability are obtained by the use of the extracted bitumen which cannot be expected from the wretched stuff prepared from the ingredients to which we have alluded. At the same time, it is equally necessary to ensure good and sound workmanship in the laying down of asphalte as to provide the best materials. There is a company which has portable machinery, especially designed and constructed for this purpose, which allows of a large area being covered in a comparatively short space of time. As we have deprecated the use of bad and inferior asphalte as exceedingly deceptive to the public, and prejudicial to the prospects of the only proper substance, it is but fair to give a few instances where the latter may be seen and its value appreciated. One of these is, in the words of Mr. Hepworth Dixon, "Her Majesty's Tower." Most of the footpaths, and some portions of the roof, have been laid for some years past with Pyrimont asphalte, and yet present no signs of deterioration. The roof of the new prison at Holloway, and the extensive footpaths around the fountains in Trafalgar-square, are other examples.

According to the climate and the purposes for which it may be intended, so can the composition and character of asphalte be varied. From its nature, it must always possess some little elasticity, even when that quality is required to be reduced to a minimum. This is one of its properties, which is frequently of considerable advantage. It renders it exceedingly valuable as a "damp" course in buildings, and much superior to slates, tiles, concrete, or other hard and unyielding substances. Considering them all on a par with respect to waterproof qualities, the asphalte alone possesses the capability of yielding to any local pressure. Consequently, if any portion of the foundation settle, the slates, tiles, or other hard substances at once break across, and the watertight continuity is destroyed. The asphalte, on the contrary, adapts itself to the settlement of the foundations, and preserves the waterproof layer intact. Anyone who has walked over a large area of properly executed asphalte cannot fail to ask himself the question, whether its application could not be extended to road and street traffic. There is no doubt but that the substitution of asphalte for granite or macadam would be hailed with ecstatic delight by the riders of bicycles. What a road to run on! A portion of Threadneedle-street has within the last nine months been laid down with asphalte, but upon a different principle to that upon which footpaths are constructed. Some time must elapse before it will be possible to judge of the suitability of this surface for the severe tax made upon its powers of resistance and durability by the exigencies of our metropolitan traffic. There is another situation for which an asphalted surface appears to be well adapted, and in which its property of elasticity can be advantageously brought into play. It is in the case where it is necessary to form a footpath on made ground. The most extensive example of this kind is probably to be found in the foot thoroughfares of the Thames Embankment, and anyone who is in the habit of traversing that on the north side cannot fail to perceive how badly the paving flags adapt themselves to the irregularities caused by the "giving" of the ground underneath. A very slight subsidence, which would be scarcely appreciable under ordinary circumstances, is quite sufficient to destroy the evenness of a flagged footway. As it is, many of the flags are disturbed to an extent which throws up one end fully an inch above its neighbour, and imparts a very jagged appearance to the surface. Taking them up and relaying them is the remedy, but how often this remedy will have to be repeated it is impossible to assert, for railway experience has demonstrated that it frequently requires a long time for a heavy embankment to settle permanently to its "bearings." In pointing out the manner in which paving flags behave under the conditions in question it is not intended to assert that they ought to be replaced wholesale by an asphalted surface, but had a small portion of the Embankment been covered by the latter substance, the relative merits of the two descriptions of paths would have been fairly and impartially tested. The principle of giving every method of executing any particular description of work a fair trial is one that needs urgent adoption by the various branches of our civil and military departments. By every method is signified every one that possesses manifest claims to consideration, and does not, of course, include the mere ideas of inventors, or hobbies of patentees which are destitute of all practical utility. But, when an individual or a company is willing to test, solely at their own expense, any plan they consider likely to effectually accomplish any desired object, they ought to be allowed to have an opportunity of so doing. It might be urged that the public ought not to be put to any inconvenience with respect to interruption of the ordinary traffic, supposing the trial concerned the taking up of any part of a street or thoroughfare. What with gas and water companies who are perpetually breaking up the streets, the public is pretty well used to such inconveniences. Moreover, as the object of all proposed improvements is to benefit the public, the end fully justifies the means. There are undoubtedly many valuable inventions totally lost to us solely because we never permitted them to be fairly and dispassionately investigated, and their practical merits submitted to the crucial test of actual experience.

IODIZED COLLODION IN PHOTOGRAPHY.

IN the early days of photography collodion containing iodides only and no bromides was in almost exclusive use. Spots, fogging, and all kinds of evils then beset the photographer, who was not long in tracing most of these evils to impurities and too much acid in the nitrate of silver crystals which were used in making the sensitising bath. Still a residuum of imperfectly understood causes of failure remained, until bromo-iodized collodion was introduced in company with development with protosulphate of iron. This very much reduced the chances of failure, so that commercial photographers of necessity adopted the new plan, and then, after purer materials began to be used in the manufacture of collodion, failures ceased altogether among intelligent photographers who used moderate care in the selection of their chemicals.

With the light of the better knowledge thus gained by photographers by experience, Mr. Thomas Sutton, B.A., of Jersey, tried some experiments with the old-fashioned simply iodized collodion, in conjunction with the purer chemicals of later date. He found it to be much less liable to spots and markings than generally supposed, and the few sources of error remaining he traced to impurities in re-crystallized nitrate of silver, quite pure enough, however, for use with bromo-iodized collodion. He accordingly exerted himself to introduce an exceedingly pure description of nitrate of silver into the market, and of all the strong proclivities of Mr. Sutton to turn his discoveries into commercial profit, for this one he certainly deserves the thanks of photographers and gain to himself. With such nitrate of silver, and other chemicals of moderate purity, it was found that the sources of failure with iodized collodion had been abolished, but by this time the new method of operating had struck such deep root that few photographers re-entered the ancient path thus cleared of its difficulties by industrious experiments.

The statement of facts in the foregoing preamble is intended to lead to the consideration of the question whether the desirability of returning to iodized collodion in portraiture is not worth very serious consideration. In the first place, every plate coated with iodized collodion abstracts by chemical decomposition much less silver from the bath than bromized collodion, therefore it is cheaper to use. In the second place, the iodized plate requires a shorter time of immersion in the bath, so is cheaper in the saving of time. An iodized collodion requires about three minutes in the bath, a bromized collodion requires about twelve minutes in the bath, and a collodion containing chloride only requires more than half an hour in the bath, as discovered by Mr. Harrison, to give a good film. Iodized collodion again requires the weakest bath of the three, 25 grains of

nitrate of silver to the ounce being sufficiently strong; the other two collodions require 60 and 100 grains to the ounce respectively. Another advantage of good iodized collodion is that it permits of very short exposures and rapid development with pyrogallic and formic acids, so rapid, indeed, that it is doubtful whether iron development will give more rapid results. The advantage of this is that with a suitable pyroxyline in the collodion and pyrogallic development a good intense picture can be obtained at once, so as to save the photographer all the dirty work and waste of time of after-intensification. The ordinary formic acid of commerce is very impure, and nine samples out of ten are pretty sure to cause fogging and other evils. The pure monohydrated formic acid must therefore be used. This is only obtainable with difficulty, and is usually imported by wholesale dealers from the continent; we do not know that it is on sale in London by any chemists except Messrs. Hopkins and Williams, for several photographic chemists who have it on their lists have it not in stock. The pure acid, when obtained, should be diluted with water, as it acts very painfully upon the flesh. The quantity of it required in the developer is so small that it is less expensive to use than the acetic acid ordinarily employed for the purpose. Some of those very few photographers who have tried iodized collodion now that the conditions of invariable success with it are known say that it gives rather hard pictures. So it does when the lighting of the sitter is the same as for bromo-iodized collodion, and some of the hardness complained of was caused by the too great reduction of the time of exposure in the attempt to get instantaneous results under unfavourable conditions. M. Claudet, F.R.S., frequently used this process in portraiture with much success as to rapidity, but his glass house had too much top light and too little side light to give the best results by any process.

What is required is that some commercial photographers should give this process a long and fair trial. The probable result will be a saving in time and money and the general abolition of the tiresome work of intensification. But the chemicals must be pure to avoid failure, and some little care must be taken to light the sitter properly. Much as iron development is in vogue, we know some photographers in a very large way of business who turn out capital portraits regularly by the old pyrogallic development. It would be well to try the merits of the old plan once more, with the present advantage of higher knowledge and purer materials.

THE LATE PROFESSOR GRAHAM, F.R.S., MASTER OF THE MINT.

THE announcement made in our columns last week of the alarming illness of this eminent chemist no doubt prepared the public for the event which has now taken place—his decease. The unfortunate gentleman never rallied from his severe and somewhat sudden attack of inflammation of the lungs, but rapidly sank, and died on the night of the 16th inst., at his house in Gordon-square, London. Mr. Graham was, to a certain extent at least, what is known as a self-made man. He was, in fact, one in the ranks of that numerous army of adventurous North Britons who, year by year, find their way southward, and who succeed in securing for themselves so many of those rich prizes which are the rewards of energy, perseverance, and tact.

The late Master of the Mint was born in Glasgow in 1805, his father having been a manufacturer in that city. His boyhood was spent in the midst of that industrial hive, and he obtained the rudiments of education in the grammar school of his native place. At a proper age he was entered as a student in the University of Glasgow, and in 1824 took the degree of M.A. Under Dr. Thomson, then Professor of Chemistry at the University, young Graham took his first lessons in the science of which he afterwards became a celebrated expositor. For two years the young scholar pursued his studies in chemistry, diversifying the labour with mathematical pursuits. Subsequently he removed to Edinburgh, where he gained the favour and patronage of Sir John Leslie, so well known for his investigations of the phenomena of heat. Mr. Graham returned to Glasgow in 1828, and established a public laboratory there for the study and practice of chemistry. This led to his appointment as lecturer at the Mechanics' Institute of Glasgow, and where he became somewhat popular. In 1830 he was nominated Andersonian Professor of Chemistry in the University. This post he held until, his fame having found an echo in the British metropolis, he was appointed to the chair of chemistry in University College. In 1837, Graham was elected a Fellow of the Royal Society, and for the space of ten years he held also the office of Chemical Examiner in Arts in the London University. In 1846 he was named as a member of the commission appointed to report to Parliament on the ventilation of the Houses of Parliament. Mr. Graham was the first President of the Chemical Society, which he was instrumental in founding (in 1841), and to the transactions of which he largely contributed. At the Great Exhibition of 1851 the subject of this memoir acted as vice-president and reporter to the jury on chemical and pharmaceutical products.

It is scarcely possible on this occasion to enumerate the various scientific discoveries and inquiries with which Mr. Graham's name is associated, but the most remarkable and important, perhaps, is his elucidation of the law which governs the diffusion of gases. For his investigations into and demonstrations of this peculiarly interesting subject he received the Keith Prize at the hands of the Royal Society of Edinburgh, and the Gold Medal from the Royal Society of London. He was besides connected honorarily with the Institute of France and the Academies of Washington, Berlin, Munich, Turin, &c. In the year 1855 Mr. Graham received the appointment of Master of the Mint, rendered vacant by the resignation of Sir John F. W. Herschel. It is understood that the late Prince Consort was the mainspring of this upward movement in the career of the late Professor. He had previously filled the office of an assayer to the Mint, and it was imagined by his patron that his chemical knowledge would be found valuable in that establishment. This, however, was scarcely the case, as other assayers were appointed whose duty it was, and is, to submit all bullion presented for coinage, and all coin produced from it, to scientific control. It is by no means necessary, therefore, that the Master of the Mint should be a chemist. Far less is it essential that he should be an astronomer! The real qualifications for the post are a complete acquaintance with machinery and mechanical operations, mathematical knowledge, and familiarity with the art of banking and the laws of political economy. It is questionable whether the late Master's chemical acquirements were of any real service in the money manufactory itself, however useful they may have been to the world at large. At his laboratory in the Mint, nevertheless, many experiments in physical science were no doubt conducted, and many of Mr. Graham's more recent contributions to the scientific wealth of the country were there concocted. His assistants—Messrs. Stoikowitsch and Roberts—were his able and zealous co-operators. As has been stated, Mr. Graham became Master of the Mint in 1855; this was some three years after the departure of the Company of Moneyers, and the reorganisation of the establishment by Captain (now Lieut.-Colonel) Harness, R.E., who, it was thought by some, might well have been promoted to the Mastership after the successful accomplishment of that work.

The new Master found, on his assumption of office, that its duties were onerous and difficult in themselves, and that they were not diminished by a certain spirit of personal antagonism existing within its walls. His own close attention to business, and the zealous aid which was given him by some of his subordinate employés, enabled him to surmount many obstacles of a social and practical nature, and to establish a control which was paramount and effective. The remodelling of the copper coinage in 1860-1, and its re-issue in the form of bronze, may be justly considered the most arduous and important work executed during the fourteen years of Mr. Graham's rule at the Royal Mint. The advantages which have resulted from this change in the subordinate currency of the United Kingdom are too well known to need further comment here, but it may be remarked that, instead of the pockets of the British public being encumbered with five or six thousands of tons of copper money, two or three thousand tons of bronze are all they now have to support. Within the fourteen years alluded to nearly one hundred millions of sovereigns and half-sovereigns, and some two or three hundred millions of silver coins, have been stamped into existence at Tower Hill. In the interests of truth it must be admitted that the late Master of the Mint did not seem to understand, or at least did not always practice, that gentle art which has the effect of inspiring colleagues and subordinates with an affectionate attachment to their chief. He was consequently not a popular Master, however conscientious he may have been in fulfilling the requirements of his office.

Mr. Graham's remains were removed to Glasgow on Tuesday last, and his funeral took place at the scene of his nativity yesterday. It is but seven months since his brother John, who filled the post of chief coiner for a brief period, preceded Thomas Graham along that dark vale whither the footsteps of all humanity tend. The Royal Mint was closed yesterday as a tribute of respect to the memory of its departed Master, who, it is somewhat singular to observe, is the only one that has died in office since the days of Sir Isaac Newton.

THE STEAMSHIP "MALTA."

ABOUT two months since we placed before our readers some particulars respecting the steamship "Malta," a vessel which was then attracting notice on account of being the first ship built and engined complete by a single firm on the Wear. She was turned out by Messrs. Oswald and Co., of the Pallion High Yard, Sunderland, and has since made a most successful trip, particulars of which and of her machinery it is now our purpose to give. The "Malta," we may here mention, has a length of 221ft. over all, with a breadth of 30ft. 6in. and a depth of 17ft., her builder's measurement being 919 tons, and her dead weight capacity 1,300 tons. She is fitted with water ballast tanks (in the form of a double bottom) containing 180 tons of water, and so arranged that they can be pumped out in 1h. 15m. The "Malta" is fitted with screw engines of the inverted direct-acting type and on the surface-condensing high-pressure expansion principle, with improved expansion valves. They have a nominal horse power of 99, and an indicated power of 659. The cylinders are 39in. in diameter, length of stroke 33in., length of connecting rod 6ft., diameter of piston rod 4¾in., diameter of crank shaft 8¼in., diameter of air and circulating pumps 20in. The area of condensing surface in the surface condenser,

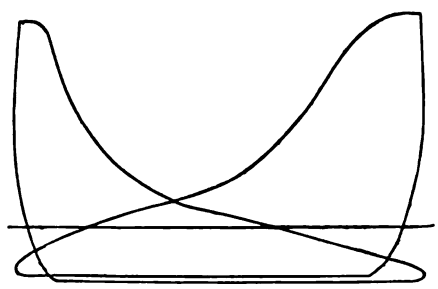
with 1in. diameter brass tubes, is 10 square feet per horse power.

In the design of these engines simplicity and accessibility of working parts, and regularity, compactness, and proportion of the stationary parts, as the framing, &c. (or what may be termed the architecture of the machinery), were the chief points aimed at, and certainly the Messrs. Oswald have been very happy in this respect in this their first production. The expansion valves are not arranged for a variable expansion, but have a set expansion cutting off at 6½in. of the stroke. This expansion cannot be reduced, but can be increased by means of the sweeps, *i.e.*, by linking them up from 2in. to 6in. The advantage considered to be gained with the "set" expansion is that the engineer in charge cannot alter it as he likes. In practice, with the variable expansion engines it is found that the consumption of fuel is much larger than it should be, and the inference drawn from this is that the engineers, when away, grow careless and do not treat with the expansion properly. The cylinders of these engines are steam jacketted around as well as at top and bottom, and are supplied with superheated steam direct from the superheater. The cylinders are also fitted with small independent slide valves, to be used for starting the engines when necessary.

The cylinders are supported by four cast-iron main frames of the hollow column form and of the O G shape, which stand on a ribbed box, bottom, frame, or bed-plate. Rectangular recesses are cast in this bed-plate for the bearers of the crank axle. Provision is also made in the bed-plate for the air and circulating pumps to be placed immediately behind the hinder main frames or columns, on which projections are cast for carrying the bearers of the inside and outside side levers, which work the pumps by means of the piston rod, to which one end of each of the side levers is attached by a gudgeon. One pump to each engine serves as the circulating and air pump combined, the air pump being at the bottom and the circulating arrangement at the top. The air pump valve boxes are contained in the bed-plate, those for the circulating pump being cast separately and fixed overhanging the top of the pump. The feed and bilge pumps are side by side, and are placed on the outside of the air and circulating pumps. The whole of these pumps are connected with one crosshead, and the side levers which work the pumps are attached by means of links to these crossheads. The surface condenser also stands on the bottom frame, immediately over and in immediate connection with the air pump valve boxes. It is placed directly between the air and circulating pumps and the two hinder columns, there being sufficient space left between them for the clearance of the hinder levers which work the pumps. The tubes in the condenser are placed horizontally, and the doors are arranged so that the tubes can be drawn through in between the engines or behind them if required at pleasure. The circulating water is admitted at the top of the condenser, which is so constructed, divided, and partitioned that the circulating water travels backwards and forwards the length of the condenser four times before being discharged from the bottom of the condenser.

The slide valves are placed in between the cylinders, and are worked in the usual way with eccentrics, links, &c. The reversing gear is of a simple, quick, and powerful construction, and is fixed on the front after column with the reversing wheel. The handles for the starting valves, the throttle valve, and regulator to steam jackets and safety valves are within immediate reach. The boilers, two in number, are on the circulating multitubular return tube principle, and of the round form, fitted with 3¼ lap-welded iron tubes. The boilers are 9ft. diameter and 11ft. long, and have a heating surface (with both boilers combined) of 2,909 square feet. There are two furnaces in each boiler 2ft. 6in. diameter. The superheater, which is placed horizontally on the top between the two boilers, is 5ft. 6in. diameter and 7ft. long, and is fitted with 4in. tubes, the uptake surrounding the whole of it. The water tubes fitted in the boilers help to make the circulation most perfect.

The "Malta" made her first voyage from Sunderland to Rotterdam, a distance of about 300 miles, in 26 hours, the weather being favourable and the vessel in good trim. The consumption of fuel was measured and found throughout to be from 9½ to 10 tons in the 24 hours, or 1·42 on an indicated horse power of 659, or under 1½lb. per indicated horse power per hour. The safety valves are loaded to 50lb. per square inch, the working pressure averaging 45lb. The vacuum was continual and steady at 26in.; the average revolutions were 63; the steam was superheated from 320 to 350deg. Several indicator diagrams were taken which were highly satisfactory. One of these diagrams we give in the annexed figure. This diagram was taken with steam at 50lb. per square inch, number of revolutions 64.



The "Malta" did her 10 knots or 11½ miles per hour easily on a consumption of under 10 tons of coal in the 24 hours. The carrying capacity of the vessel is 1,300 tons dead weight, so that she will carry 100 tons of dead weight 100 miles on a consumption of 7½cwt. This is very low indeed, and we are not aware that there is any other vessel running which has done the same, except on a considerably higher consumption. On the whole, the construction and performances of both engines and vessel are alike satisfactory, and reflect great credit upon the firm who built and engined the "Malta."

ENGINEERING PAPERS.

UNDER the above heading we have year by year for some years past noticed a volume replete with original information of a practical character upon the varied subjects which go to make up the sum of engineering work. This volume consists of a series of well illustrated papers which have previously been read before the Society of Engineers, and which, with the interesting discussions thereon, form its yearly "Transactions."* During the year 1868 the Society was under the able and energetic presidency of Mr. Baldwin Latham, who inaugurated the session by an address which mainly discusses sanitary matters, upon which Mr. Latham is well known to be an authority. The modern works of sewerage and water supply have been great experiments made for the purpose of improving the state of the public health. That they have accomplished the end for which they were inaugurated is shown by a table which Mr. Latham gives, and which contains the results in twelve towns. From this table it is shown that in Cardiff and Newport the saving of life per cent. of the population since the works have been carried out is 32. In Croydon it is 22, in Macclesfield and Salisbury it is 20, whilst in other places it is proportionately high. This address, with which the volume opens, is an admirable exposition of the principles of sewerage and irrigation, and forms a striking comment upon the great value of sanitary works.

Following the President's inaugural address comes a valuable paper by Dr. Cullen on the surveys of proposed lines for a ship canal between the Atlantic and Pacific oceans. The necessity for a direct route from Europe and the United States to the western shores of America, Australia, and China has long been fully recognised, and several surveys have been made with a view to carrying out the project. Dr. Cullen has himself made a survey, and he gives his own experience as well as that of others who have accomplished the same object. These several surveys and reports all agree as to the desirability of the undertaking, although they differ as to its practicability. The Cordillera and the Rocky Mountains appear to interpose an almost insuperable barrier to the work. Dr. Cullen, however, seems to have hit upon a valley between these two mountain ranges, although there is great doubt from contemporaneous evidence whether such facilities do really exist. Our readers may remember that we announced a few months since that a company in America was preparing to carry out the scheme. A subsequent announcement, however, showed that the negociation had fallen through. We then remarked that the opportunity was again open for English capitalists to step in and promote the undertaking. Whoever next may set to work upon it will find Dr. Cullen's paper—as well as a second and third, by the same author, upon the Panama Railroad and upon the Isthmus of Darien and the ship canal—most useful in connection with the question. They contain all that is known on the subject of inter-oceanic communication, and are illustrated by maps and plans and sections of proposed routes. Undoubtedly, a ship canal for connecting the Atlantic and the Pacific Oceans through some point of the Isthmus of Panama or Darien would prove a most desirable undertaking, and one which would be an advantage to all the trading nations and maritime powers of the earth.

We next come to a paper by Mr. F. C. Danvers on the subject of engineering in India, in which the author refers to the gigantic works which have been carried out in India in past ages, and of which ample evidences remain. Roads, however, appear to have been sadly neglected, probably because there was an almost total absence of wheeled conveyances. In this respect, however, modern engineers have improved the country, and also with respect to bridges, which render the roads very perfect. The author also touches upon the method of carrying out the works of public departments in India, and the salaries paid to engineers of various grades. He admits that the pay is comparatively small at the outset, but against this he places the fact that it is sure, and this is no weak argument at the present time, when engineering appointments at home become more and more rare every day.

After Mr. Danvers' paper is a report of a very pleasing character. It is that of the presentation of a testimonial to Mr. Alfred Williams, who has been for many years past, and still is, the honorary secretary of the Society of Engineers. The testimonial consisted of a handsome silver tea and coffee service, bearing an appropriate inscription, and accompanied by a suitable address. Having upon many occasions, in the interests of this journal, experienced the greatest courtesy at the hands of Mr. Williams, we heartily concur in the concluding wish of the address, that he may continue for many years to retain the post of honour which he now occupies in the Society.

Passing on to the next paper we find a description of the Redhill sewerage works by Mr. Sydney A. Reade. Although the sub-

* Transactions of the Society of Engineers for 1868. London: E. and F. N. SPON, 48, Charing Cross. 1869.

ject is a special one as far as regards site, yet the paper is a valuable one, inasmuch as it contains a large amount of practical information upon sewer construction which applies to the matter in general. The forms and dimensions of various kinds of sewers are given, with the rules according to which they are constructed, and the methods upon which they are built. Manholes, ventilating shafts, gulleys, &c., &c., are fully described and illustrated. The Redhill sewage works were carried out under great difficulties, and cost more than usual in consequence of the nature of the subsoil. The methods adopted, however, proved thoroughly successful, and form a practical example invaluable to those who may have the like difficulties to encounter.

The paper following is by Mr. Arthur Rigg, jun., who has made some important experiments with the screw propeller, and has here embodied them for the use and guidance of those interested in screw propulsion. There are many curious theories afloat respecting the screw propeller and the way in which it acts with relation to the water. It has been frequently assumed that water acts the part of a solid in resisting the screw, but this Mr. Rigg shows to be a fallacy This is almost self-evident, as water cannot act like a liquid and yield to the ship's advance, then immediately change all its properties and become a solid resistance to the screw at the stern. The various points to be considered in arranging the best screw propeller for any particular example are carefully gone into, and the results of the author's experience and observation are given, the principles which regulate the true proportions of the screw being laid down. This paper is followed by a most interesting discussion, in which several conflicting opinions are given upon the subject.

We next have a paper by Mr. Henry Gore on modern gas works at home and abroad. The paper is by no means exhaustive, but it touches upon the main points of manufacture, and describes some of the methods pursued in different localities abroad. The author deals with the leading principles of construction essential to the production of the greatest amount of light from a given quantity of materials employed, and to the situation in which the manufacture may be most successfully conducted. In the adjourned discussion which follows this paper, Mr. Ewing Matheson describes Best and Holden's machine for charging and drawing retorts. This machine is stated to be in successful working at the Alliance Gasworks, Dublin, although it was not received with much favour by several gas engineers of experience at the meeting.

Following Mr. Gore's paper comes one by Mr. E. Matheson on the accumulator cotton press. After describing several presses for packing cotton, including Hodgart's, Mason's, and M'Combe's, the author gives a detailed description of that by Mr. George Ashcroft, which is on the accumulator principle, and was designed to fulfil the two main requisites of power and speed. During the time of filling the boxes with cotton, changing them, and hooping the bales, the pumps are quietly at work forcing up the accumulator box, which, at the proper moment, gives forth all its power, and does all that is required in a few seconds.

The two remaining papers are upon one subject—that of the application of steam to the cultivation of the soil. They are by the President, Mr. Baldwin Latham, and, so far as the matter has been treated, they form a valuable history of the subject. We say "so far" as it has been treated because the author has only pursued the subject up to a certain point, and we understand that further papers in continuation are being prepared by the author for the Society. For these we shall look with interest; in the meantime we shall glance at the papers before us, as we hope at a future time to be able to reproduce portions of them in our columns. The author points out the advantages of steam culture, and shows how far superior it is to that done by horse labour. It is not an entire substitute for horses, but it will perform the hard work better and cheaper than it can be done by horse power. The author then gives the early history of steam cultivation, showing that its present position is due to the aggregation of the ideas of a great number of inventors. He divides the systems into four classes, viz.:—1, Traction engines or machines which draw the implements of cultivation after them; 2, locomotive engines travelling upon fixed railways; 3, fixed engines communicating the power to the implements by the agency of chains or ropes; 4, traction engines moving along the headland or other part of a field and working implements by the agency of wire ropes. The latter portion of the first paper is occupied with a consideration of engines of the first class. The second paper is devoted to those of the three remaining classes, and to a discussion of the relative merits of stationary and locomotive engines when tilling the soil. These papers are accompanied by nine folding plates containing more than thirty illustrations of the various engines and systems of cultivation referred to. It will thus be seen that these papers possess a special interest and value, as they illustrate the history of steam cultivation from the earliest times down to the present.

Out of this varied collection of contributions three have been selected by the council for premiums, or, more correctly speaking, three authors have been selected, as Dr. Cullen himself has three papers to which a premium has been awarded. Mr. Reade received a premium for his paper on the Redhill sewerage works, and Mr. Rigg for his paper on the screw propeller. The president, however great may be the value of his paper, cannot have a premium awarded him, as by the Society's rules members of council are disqualified in this respect, otherwise there can be no doubt but that it would have been honoured with the recognition it deserves.

It will be seen that the volume of Transactions before us is a valuable contribution to scientific literature, and will form a standard for reference upon the several subjects on which it treats. The illustrations to all the papers are executed in excellent style, and we hardly know which to admire most, the tinted maps which accompany Dr. Cullen's papers or the finely executed mechanical drawings attached to those by Mr. Latham. Certainly the volume is well got up and does credit to the members of the Society and their publishers.

TELEGRAPHIC NOTES.

IN our telegraphic intelligence last week, we noticed a letter from the solicitors to the Telegraph Construction and Maintenance Company respecting Mr. Rowett's cable and the Land and Sea Telegraph Construction Company. The secretary of the latter company now writes to say that it is quite true that the Land and Sea Telegraph Construction Company have the right to the exclusive use of Mr. Rowett's patented deep sea hemp-covered cables, and it is likewise true that the Atlantic cables are manufactured on Mr. Rowett's principles. The writer continues:—Messrs. Bircham, Dalrymple, Drake, and Co. omit, however, to state that Mr. Rowett, as patentee of those cables, has instituted suits in Chancery against the Telegraph Construction and Maintenance Company, the French Atlantic Cable Company, and other companies, to protect his rights, and these suits are being prosecuted on his behalf by the eminent firm of solicitors, Messrs. Ashurst, Morris, and Co. It was considered that Mr. Rowett's rights were of such value as to be worth acquiring by the Land and Sea Telegraph Construction Company. At the same time, the Land and Sea Company, although having this exclusive right, will be prepared to construct cables on other principles if required. A piece of the cable just manufactured under the superintendence of this company's engineer, and now being laid for the Scilly Islands Telegraph Company, can be seen at the office of the Land and Sea Company, and the secretary asserts, on the best scientific authority, that both mechanically and electrically it is greatly superior to any submarine cable ever yet laid.

It is stated that Messrs. Aubert, Gérard, and Co., of London, Paris, and Harbourg, have the sole contract for the manufacture of the cable for the International South Transatlantic Telegraph Company, the decree of which company appeared at length in the "Journal Officiel de l'Empire Français" of the 17th inst.

The number of messages over the French Atlantic Telegraph Cable during the week ending September 18 was 547, the cable charge upon them being £1,323. In the previous week, the amount was £1,068.

NOTES ON RECENT DISCOVERIES IN SCIENCE AND THEIR PRACTICAL APPLICATIONS.

PHOSPHATES AS MORDANTS—PURIFICATION OF FATTY OILS—SHELLAC VARNISH—DANGER FROM INCREASED COAL CONSUMPTION—THE PASCAL-NEWTON FORGERIES.

M. COLLAS has introduced phosphates with the idea of replacing alumina as a mordant. He first passes the tissue or yarns to be dyed through an acid bath of phosphate (say of lime or magnesia), then through the bath of colouring matter, and lastly through a weak alkaline bath. The process is particularly applicable, he states, for aniline colours, and most especially for aniline purple. Lakes can also be prepared by means of phosphates, preferably with phosphate of lime. Thus, to obtain a cochineal lake, an infusion of the colour is first made, and then a gelatinous precipitate of the phosphate is added, and the mixture is well stirred for a time. The colouring matter is precipitated as completely as by alumina. Insoluble colouring matters may be used as dyes by employing gelatine in combination with phosphate of lime.

A new process for purifying fatty oils is given by M. de Keyser, which may be very effective, but can hardly be cheap. To 100 kilogrammes of the oil he adds 600 grammes of strong caustic ammonia, and mixes the two thoroughly by continued agitation. The mixture is then allowed to settle in a close vessel, and after three days we read that the oil may be drawn off quite bright, the ammonia and all the impurities having gone together to the bottom.

That shellac is soluble in a solution of borax is a well-known fact, and the solution has received some applications. As a varnish, however, it does not answer well, on account of the quantity of borax dissolved. Shellac is also soluble in ammonia, and the solution makes a very good waterproof varnish. Puscher publishes some suggestions for making varnishes of various colours with the solution. Most of the insoluble earthy colours may be mixed with it. Sulphate of lime, however, is said to decompose the solution. Extract of logwood easily dissolves in it, so likewise does aniline green. We have long employed it to make an indelible ink, which is especially useful for laboratory labels, a mixture of lampblack with the shellac solution remaining quite unaffected by acid vapours. The coloured solutions are, in fact, available for many decorative purposes. The plain solution is made by macerating three parts of white shellac in one part of strong ammonia, diluted with six or eight parts of water. This mixture must be frequently shaken for twelve hours, after which the solution may be completed by the application of a gentle heat.

The consequences of the enormous extension of the consumption of coal are serious enough. Whether Mr. Jevons be right or wrong in the estimate of the time at which our coalfields will be exhausted, the time no doubt will soon come when coal will advance in cost. That is a certain source of inconvenience to the pocket; but a

Frenchman has recently speculated on a more serious consequence to the health of the world from the vastly increased consumption of coal. He imagines the world being gradually suffocated by means of carbonic acid. The same idea occurred to us, and probably has occurred to many others; but a few calculations soon set our minds at ease. We found that it would take some thousands of years to bring the proportion of carbonic acid in the entire atmosphere up to that which has been found in a London theatre. At first sight, the Frenchman's notion seems plausible enough. The consumption increases, while vegetation, by means of which carbonic acid is removed from the air, proportionably diminishes. Whether an acre of cereals will assimilate as much carbonic acid as an acre of forest trees we cannot say. But certain it is that forests are disappearing, and hence the unhappy savant's alarm. A few figures, however, will show how remote the danger is. The proportion of carbonic acid in normal air is about 0·04 in 1,000 parts. The amount of carbonic acid in the whole of our atmosphere is calculated, we believe, at about two and a half billions of tons. If the two hundred millions of tons of coal now raised annually in all parts of the world were completely burned, they would add to the atmosphere about five millions of tons of carbonic acid. Any reader who is disposed may calculate for himself how long, at this rate, it would take to bring the atmosphere up to the dangerous limit, four per cent. of carbonic acid.

Having several times, in these notices, referred to the forgeries imposed upon M. Chasles as the writings of Pascal, Galileo, and some other learned men of the same time, we may mention that at last M. Chasles is convinced that he has been duped. The forger has been arrested—or perhaps we ought to say the copyist, for, since he turns out to be a man ignorant of Latin, Italian, and mathematics, he could hardly have composed the letters. There are others, most likely, who assisted in the fabrication of the correspondence, the man arrested being simply a somewhat skilful imitator of old writings. His trial will probably produce some curious revelations.

THE LIBRARY OF THE BRITISH MUSEUM.

DURING last year 42,331 volumes and pamphlets were added to this library (including books of music and volumes of newspapers), of which 992 were presented, 6,099 were received in pursuance of the laws of English copyright, 346 were received under the international copyright treaties, and 34,894 were acquired by purchase. There were added also 33,403 parts of volumes (or separate numbers of periodical publications and of works in progress). A total of 1,145 sets of newspapers were received from the Inland Revenue offices of the United Kingdom, of which 131 were published in Scotland, 138 in Ireland, 238 in London, and 638 in the rest of England. Of music, 2,121 pieces were acquired, each piece complete in itself, of which 1,527 were received by English, and 576 by international copyright, and 18 were purchased. Of 779 portions of musical works in progress, 473 were received by English, and 306 by international copyright, and 253 works of music of greater extent than single pieces were also acquired, comprising 25 by English, 66 by international copyright, and 162 by purchase. A total of 5,773 articles were received in the department, not included in the foregoing enumeration of volumes and parts of volumes, consisting of playbills, single pieces of music, broadsides, songs, ballads, and other miscellaneous items, giving a grand total of 81,507 articles received during 1868 in the department.

THE NEW HARBOUR AND DOCKS IN TABLE BAY.

THESE extensive works, which have been in progress since 1860, have recently been completed. The undertaking appears to be of a thoroughly comprehensive character; it consists of a breakwater about 2,000ft. in length, an outer basin of 6 acres connected with an inner basin or dock of about 10 acres, with 24ft. of water at low water, and 30ft. at high water of spring tides. In connection with this basin, there is a patent slip, which is adapted for the repairs of the largest class of shipping. The total length of quayage in the dock is 2,500ft., and in the basin and along the jetties, 1,400ft. Ample provision has also been made for wharfage purposes and the erection of warehouses. The total amount expended upon the works up to the present time is about £345,000. They were designed by Mr. Coode, C.E., the engineer-in-chief in England, and have been carried out under the able and energetic supervision of Mr. A. T. Andrews, C.E., the resident engineer in the colony. Water was admitted to the inner basin on the 21st ult., to the great satisfaction of the colonists, whose prosperity will be enhanced by the works just completed.

TRIAL TRIP OF THE "EUROPE."

A SATISFACTORY solution of the all-important question of the economical propulsion of steam vessels has just been arrived at in the "Europe" steamship, which was built by Messrs. Napier for Messrs. Marc Fraissinet, Pere et Fils, the well-known steamship owners of Marseilles. Her dimensions are:—Length, 315ft.; breadth, 37½ft.; depth, 29½ft.; tonnage, builder's measurement, 2,130 tons; engines, of the high and low pressure kind, 230-horse power nominal; boilers, cylindrical and tubular. The trials of the "Europe" took place on the 11th and 14th inst., on the estuary of the Clyde. On the date first mentioned, the "Europe" went out for her high speed trial, and, while carrying a deadweight cargo of coal and iron of 2,220 tons, attained an average speed, at the Admiralty measured knot, at Wemyss Bay, of 11·14 knots per hour. This result, so highly satisfactory, was obtained in spite of the tempestuous weather experienced, and with a consumption of fuel very considerably under the quantity stipulated. The second trial, which lasted for twelve hours, was for the purpose of ascertaining the vessel's normal speed and consumption of fuel when loaded at sea. On this occasion, the "Europe" started from the Tail of the Bank at six a.m., under the same conditions as regards draft, displacement, and weight as on the former trial; and, notwithstanding the still stormy state of the weather (a gale blowing the whole time of the trial), she continued running for twelve hours between the Cloch and Cumbrae Lights, realising an average speed for these twelve hours of over 9·6 knots per hour, with a consumption of fuel as before, in every way satisfactory, being at the rate of 1·9lb. per indicated horse power per hour, a rate of consumption very much under the stipulations of contract. We understand that Messrs. Napier have a second vessel—sister ship to the "Europe" —on hand for the same firm of owners.

THE IRON AND STEEL INSTITUTE.

THE first provincial meeting of the members of the above Institution was held at Middlesborough. The proceedings commenced on Tuesday last, and included meetings for the reading of papers bearing upon the iron trade, visits to the ironworks in the Cleveland district, and a dinner at Saltburn, where the Institute was entertained by the local iron trade. A great many members of the iron and steel trades were present. The papers read were contributed by Messrs. Isaac L. Bell, J. T. Smith, Edward Williams, C. W. Palmer, R. Howson, T. Whitwell, G. H. Benson, and J. P. Budd, and were all upon subjects more or less intimately connected with the manufacture of iron. The conception of this Institution occurred about a year since, when a paper was read at the ironmasters' quarterly meeting in Newcastle by the secretary to the trade, suggesting the establishment of a scientific institute for the iron trade, somewhat similar in its constitution to the technical societies connected with civil, mechanical, and mining engineers. The proposition was well received, and a committee was at once appointed to lay the plan before the iron and steel trades. The efforts of this committee very soon resulted in the enrolment of nearly 200 gentlemen associated with these trades as members. The Duke of Devonshire, chairman of the Barrow Hematite Steel Company, was elected the first president, and the inaugural meeting was held in the rooms of the Society of Arts at the end of June last, when the president delivered an able address. At the meeting in London invitations were received from the North of England iron trade soliciting the Institute to hold its first provincial meeting in the Middlesborough district, which was accepted.

ONE hundred and ten thousand pilgrims are estimated to have assembled at Mount Ararat, in the late Mecca pilgrimage, or about 25,000 more than in 1868.

PONTOONS FOR TRANSPORT SHIPS.

THE question of having pontoons for our transport ships was first mooted by Admiral Mends some two years since. Upon his recommendation, some pontoons of cylindrical form were constructed of steel by Messrs. Maudslay for the "Serapis." Four of these were made to constitute the raft, the weight of each being about 55cwt. On the official trial of them it was suggested that pontoons constructed of Mr. Clarkson's patent cork material would possess qualities of lightness, strength, and buoyancy peculiarly suitable for the operations such pontoons would be called upon to perform, and that they would also be more easily repaired if damaged by musketry fire. Four pontoons were therefore ordered of Mr. Clarkson for experimental trial, and these were successfully launched, on Monday afternoon, at East Greenwich. Their dimensions are:—Length, 36ft., diameter, 4ft. 6in. The construction is as follows:—A light framework is made of wood as the skeleton of the structure. The form is then completed by planking of ¼-inch thick pine wood, both sides of which are covered by stout canvas adhering closely and firmly to the surfaces by a waterproof solution not affected by the variations of heat within the limits of terrestrial atmospheric temperatures. Over this, again, sheet cork is applied by the same adhesive substance; the whole pontoon is coated with the solution, and a strong jacket of canvas is superadded as the external covering. On the lower side of the pontoon is a keel and stem and stern post firmly bolted through to kelson and corresponding upright so as to give great longitudinal strength; and, combined with the sectional plates, equal vertical stiffness is obtained. The advantage of this material is that it possesses elasticity and such capacity of cushioning blows or thrust that the vessel receives no injury from such concussions as would be liable to fracture or indent metal structures; and even with the passage of shot, there is the total absence of splinters, and a natural tendency on the part of the cork material to close up the orifice made by the missile. Repairs are temporarily made by merely plastering canvas over the hole or fracture. The whole vessel, indeed, may be renewed by recoating with canvas, as the internal substance of the fabric, namely, the cork material, is scarcely at all subject to decay. The pontoons, which only weigh about 26cwt. each, were floated down the river to the factory of Messrs. Maudslay, Sons, and Field, where they were fitted together by spars and lashings, and a stage or platform for landing or embarking guns, troops, horses, &c., erected upon them. The pontoon raft swam very lightly and easily upon the water, and was towed down by the "Bustler" to Woolwich dockyard, where it awaits orders for official trial.

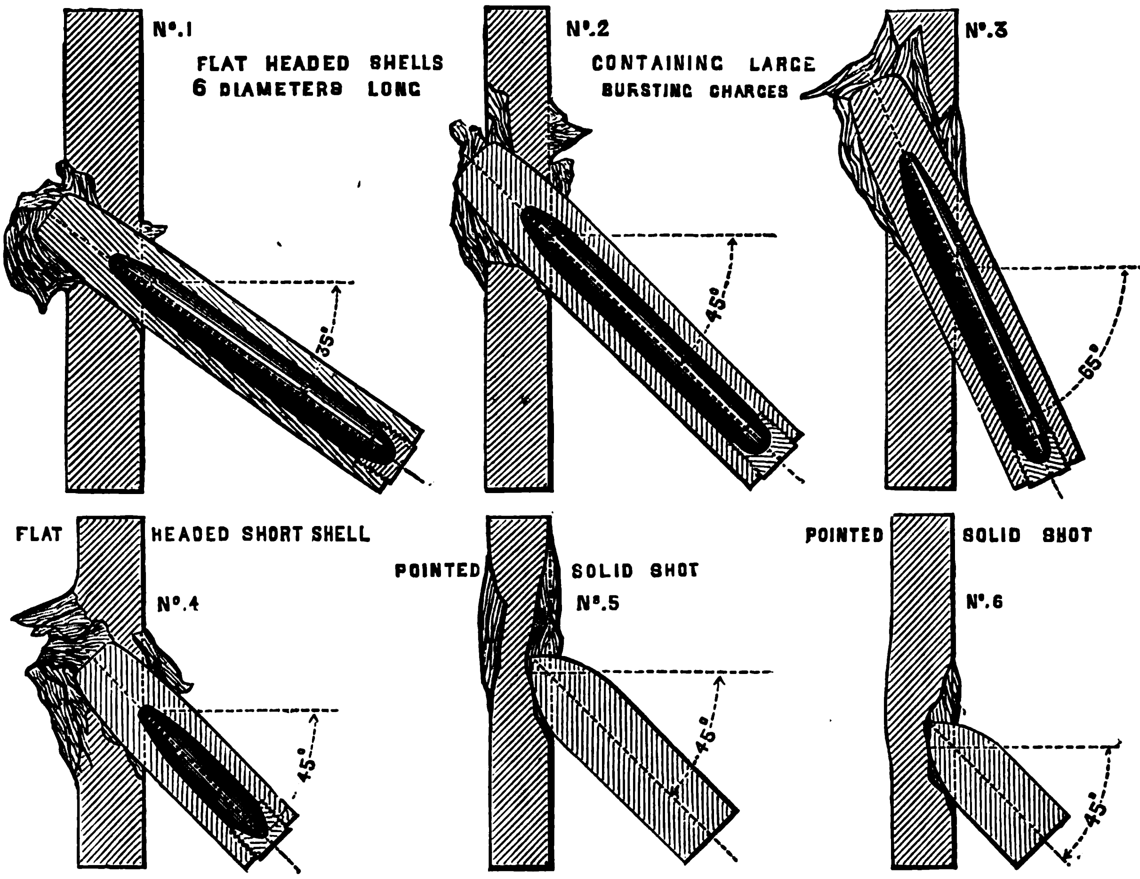
THE NEW VADE MECUM.

THE above is the name given to a very useful pocket companion, in the shape of a telescope, within which is stowed away a microscope of great power. It is the invention of Mr. C. H. Vincent, of 23, Windsor-street, Liverpool, who is now manufacturing them in large numbers. The outer barrel of the telescope is made somewhat larger than would be otherwise necessary in order to enable the microscope to be carried within it. An examination of these useful little articles proves that the telescope possesses a good range, and will be found a handy companion for tourists who do not wish to encumber themselves with a large and unwieldy instrument. The microscope has great power and excellent definition, and has the additional recommendation of not adding to the bulk of the tourist's equipment, whilst it affords all the pleasure and possesses all the usefulness of the more expensive and elaborate kinds. The price of this ingenious combination is so low as to place it within reach of everyone.

FOR some weeks past Russian military engineers have been occupied in Lithuania in selecting the best positions to be fortified for the formation of a line of defence. Among the towns to be examined for that purpose are Kowno, Grodno, Slonim, Minsk, Orsza, and Bieszenkowice. The fortresses already existing in the province are those of Brest-Litewski, Brobruisk, Wilna, and Dunabourg; those to be constructed are intended to form a strategical line with the above. A rumour is also current in military circles that the Russian government intends to transform Warsaw into a citadel of the first class.

ON THE PENETRATION OF ARMOUR PLATES.

BY MR. WHITWORTH.



ON THE PENETRATION OF ARMOUR PLATES WITH LONG SHELLS OF LARGE CAPACITY FIRED OBLIQUELY.*

BY MR. JOSEPH WHITWORTH.

AT the meeting of the British Association at Norwich last year, I contributed a paper to this Section "On the Proper Form of Projectiles for Penetrating through Water." This paper was illustrated by diagrams showing the effects produced on an iron plate, immersed in a tank of water, by projectiles with flat hemispherical and pointed heads. Copies of those diagrams are now before you. In that paper, I claimed for the flat-fronted form of projectile, made of my metal, three points of superiority over the ogival-pointed projectiles adopted in the service—1. Its power of penetrating armour plates, even when striking at extreme angles; 2. Its large internal capacity for bursting charges when constructed as a shell; 3. Its capability of passing undeflected through water, and of penetrating iron armour below the water line. This latter feature was, I think, satisfactorily proved by the experiments described last year, and I now desire to draw the attention of the Section to the experiments I have made for illustrating the penetrative power of long projectiles with the flat front that will contain large bursting charges fired at extreme angles against iron plates. These experiments are illustrated by the projectiles actually fired and the plates they penetrated, which are laid on the table, and also by the diagrams before you.

The gun from which all the projectiles were fired is called a three-pounder, though capable of firing much heavier projectiles; it weighs 815lb., and the maximum diameter of its bore is 1·85in. The charge of powder used in all cases was 10oz., and the weight of the 6 diameter projectiles is 6lb. The following were the examples submitted:—No. 1, a portion of a plate 2in. thick, penetrated by the 6 diameter flat-fronted projectile at an angle of 35deg. No. 2, a similar piece of plate, 1·7in. thick, completely traversed at an angle of 45deg. by the flat-fronted projectile, which buried itself to a depth of 30in. in a backing of iron borings. No. 3, a piece of plate 1·75in. thick, penetrated at an angle of 65deg. by the flat-fronted projectile. No. 4, a plate 1·7in. thick, nearly penetrated at an angle of 45deg. by the 3½ diameter flat-fronted projectile. No. 5, a plate 1½in. thick, against which the ogival-pointed projectile was fired at an angle of 45deg.; the projectile failed to penetrate the plate, being deflected in consequence of the pointed form of head; the distortion of its shape shows the force with which it struck the plate, and proves the good quality of the material which could resist such a test. No. 6, a plate also 1½in. thick, against which an ogival-pointed projectile 2½ diameters long, made of Pontypool white iron, with the ogival-pointed form of head, has been fired; the projectile has scooped out a furrow 4in. long and 7-10ths of an inch deep. It broke up into fragments, of which forty-eight were recovered.

The plates Nos. 1 and 3 were purposely thicker than the projectiles could quite pass through, in order that the "work" of the projectiles might be as severe as possible. An examination of the projectiles themselves will show how well they have withstood the severe strain to which they have been subjected. The data thus obtained fully establish, I think, the superiority I claimed for the flat-fronted projectiles made of my metal, and satisfactorily prove—First, that the flat-fronted form is capable of piercing armour plates at extreme angles. Second, that the quality of the material of the shells enables their length to be increased without any risk of their breaking up on impact, and thus materially augments their bursting charge capacity as shells. Third, that this increase in length, while adding to the efficiency of the projectile as a shell, in no way diminishes, but, on the contrary, proportionately improves, its penetrative power. Fourth, that the amount of rotation I have adopted in my system of rifling is sufficient to ensure the long projectiles striking "end on," and consequently to accumulate the whole effect of the momentum of the mass on the reduced area of the flat front. These experiments show further that the ogival-pointed hard metal projectiles have but small power of penetration when striking at an angle, on account of the form of the head, a projectile of Whitworth metal, with the like ogival-pointed head as the service projectile, having resisted the shock of impact without breaking up, but being deflected in precisely the same manner as the pointed service projectile, which, on account of the brittleness of the metal, was shivered into fragments. The objections I made in my paper last year to the Palliser projectile—first, that its form of head causes it to glance off from plane or convex surfaces when hitting diagonally; and, second, that the brittleness of its material renders it liable to break up on impact—I have now proved to this Section.

The facts illustrated by these experiments are not of recent discovery; ever since 1858 I have experimented upon and advocated the flat front. I have on the table a small plate, half-inch thick, experimented upon in 1862 with hardened steel bullets, fired from my small-bore rifle. No. 39 is the hole made by a flat-fronted bullet, which has penetrated the plate at an angle of 45deg. No. 40 is the indent of a hemispherical-headed, and No. 41 of an ordinary round-nosed bullet, both fired at the same angle of 45deg. These three rounds were fired in 1862. Within the last few days I have had an ogival-pointed bullet fired at the same plate at the same angle, in order to compare the effect with that produced on a larger scale on plate No. 6. It is interesting to observe how closely the results obtained with the small calibre of the rifle agree with those of the 3-pounder gun, which form the subject of this paper. The experiments recorded in the paper were made with a gun of small calibre, from considerations of economy and convenience; but I have always found that what I could do with the smaller calibres of my system could be re-produced in the larger sizes; and from my past experience I feel warranted in asserting that the effects of penetration now exhibited could be repeated on a proportionate scale with my two 9-inch guns at Shoeburyness, or with the 11-inch guns my firm are now engaged in constructing.

A glance at the formidable nature of the projectiles thrown by these guns, and a consideration of the effects they may be expected to produce, will show the importance attaching to the question of penetration of plates by long projectiles. The 9-inch guns, to which I have referred, weigh 15 tons each, and are capable of firing powder charges of 50lb. A 9-inch armour shell, five diameters long, weighs 535lb., and will contain a bursting charge of 25lb. I have no hesitation in saying that these projectiles would pierce the side of a ship plated with 7-inch armour at a distance of 2,000 yards, and at some depth below the water-line. The 11-inch guns will weigh 27 tons each, and will be capable of firing 90lb. powder charges. The 11in.

* British Association.

shells, five diameters long, will weigh 965lb., and will contain bursting charges of 45lb., and would pierce the side of the ship "Hercules," plated with 9-inch armour, at a distance of 2,000 yards. Were it not that the increased destructiveness of war must tend to shorten its duration and diminish its frequency, thus saving human life, the invention of such projectiles could hardly be justified; but, believing in the really pacific influences of the most powerful means of defence, I have named these long projectiles the "anti-war" shells. The principle I have always insisted upon, and laid down for my own guidance in artillery experiments, when either a low trajectory or penetration is required, is "that every gun should be in strength capable of withstanding the largest charge of powder that can be profitably consumed in its bore."

I have drawn up the accompanying table of the sizes of the bores of my guns, with their proportionate powder charges, and the guns will all be fully equal to this duty, and I believe the greatest possible effect, from the consumption of a given quantity of powder, will be obtained. But the guns adopted in our naval service are not equal to such a test, nor, as I believe, are they so proportioned as to realise the best effect from the quantity of powder they consume. Four guns of 12in. bore have lately been put on board the "Monarch;" they weigh 25 tons each, and charges of 50lb. and 67lb. have been fired from them with projectiles of 600lb. weight. I have no doubt that these guns have been made with all possible care, and are as strong as their material and construction admit; but if the weight of these guns was in proportion to the capacity of their bore, and if the material were the best that our metallurgical skill could supply for such a purpose, they ought to fire 117lb. of powder, and projectiles of 1,250lb. weight. They would then be efficient weapons, but at present they are more formidable in name than in reality. We are often flattered by being told that we have the best guns in the world. That may or may not be the case, but I think that we should not rest contented while we are still so far from having attained as much as our present advancement in mechanical and metallurgical science has rendered possible for us.

Mr. Whitworth's patent cartridge increases the range from 15 to 20 per cent.

IMPROVEMENTS IN PAPER-MAKING MACHINES.

THE invention we are about to describe consists in the application to paper-making machines of a roller coated with vulcanite and with vulcanised india-rubber, and which is substituted for the ordinary metal under press roll of the machine, and may be used as an under or upper second press roller. It has been patented by Mr. Robert Craig, of Newbattle Mills, near Dalkeith.

In the paper-making machine now in use, the pulp for forming the material of the paper is projected in a fluid state upon an endless wire cloth, and is kept from overflowing at the sides by endless bands (commonly termed deckle straps) after having a greater portion of the water sucked from it by capillary attraction and the action of air pumps. The endless wire cloth carrying the moist pulp upon its upper surface passes between a pair of couching rollers, the upper roller of which is usually made to press upon the under roller. These couch rollers are usually covered with a woollen jacket, and also are constructed of metal in the case of the under and of wood in the case of the upper roller. The web of paper, having passed between the upper and under couch rolls, next passes between another pair of rollers called first press rollers, which have an endless woollen cloth or felting of open texture (technically called a wet felt) between the web of paper and the surface of the under first press roll for the purpose of expressing or discharging the water contained in the paper.

The under press roll is made of iron, the endless woollen cloth or felting passing between the under press roller, and the upper press roller carries the web of paper with it between the upper and under press rollers. In so passing between the press rollers, the web of paper, as at present manufactured, is subjected to considerable pressure, by which the substance of the paper is made thinner, and the natural elasticity of the fibrous pulp of which the paper chiefly consists becomes greatly impaired. The woollen cloth or felting also being subjected to considerable pressure while passing in a damp state between the ordinary metal first press rollers carrying the moist web of paper, suffers great tear and wear from the attrition caused by the hardness and unyielding character of the two metal rollers.

By the substitution of a composite under press roller possessing a slight degree of elasticity, the web of paper, in being carried upon the endless woollen cloth or felting between the press rollers, is subjected to a less pressure than is received by the ordinary pair of metal rollers, while, at the same time, a sufficient pressure is given to effect the purposes for which the web of paper is passed through the press rollers, viz., to express or discharge the waters still remaining in the pulp to a degree sufficient to enable the web of paper to be led round the drying cylinders of the machine. From the slightly elastic and softer character of the new under press roller, the natural elasticity of the web of paper is preserved, and the fibrous substance of the web of paper not being crushed together, as in the case of the ordinary metal first press rolls, permits the web of paper in the succeeding process of drying upon cylinders to become more bulky, and therefore more valuable than by the ordinary process, and thereby the character of paper so made thus becomes more akin to paper made by hand by the great increase of body or bulkiness acquired by the freedom from the effects of the severe pressure imposed in the case of the use of ordinary metal first press rollers. The endless woollen cloth or felting, from being subjected to an elastic pressure, suffers very much less attrition or tear and wear in passing over the softer and elastic material of the under press roller, and the action of the felting is thereby such that it goes much longer without washing, and is not liable to cut by its creasing or otherwise.

In those paper-making machines in which a second set of press rollers is employed, Mr. Craig also substitutes his composite rubber roller in the place of the second under press roller, except in those machines in which the second upper press roller serves to carry the wet felt, and which has the wet felt between it and the paper. In this latter instance, the composite rubber roller will be applied to the second upper press roller, as it thus performs functions similar to the first under press roller. The materials of which the roller is composed are as follows, viz.—a metal roller of the ordinary size at present in use has applied to it a first or inner coating of vulcanite cured and hardened only to such an extent or degree as to adhere or stick firmly to the metal shell of the roller, which it covers, and then an outer coating covering the vulcanite coating, composed of vulcanised indiarubber or indiarubber not so highly cured, and therefore of a softer and more elastic character than the inner coating. With rollers thus covered, there is no tendency in the covering to separate from the metal, and the rollers consequently are thereby much better fitted to withstand the pressure which they receive when in use, and, in consequence of the interposed coating of vulcanite, are not liable to strip.

IMPROVEMENTS IN CHANNEL STEAMERS AND CABS.

THE very defective state of the accommodation afforded by the Channel steamers plying between this country and the continent having been brought under the notice of the Council of the Society of Arts, they offer the gold medal of the Society and the large silver medal of the Society for the best and second-best block model of a steamer which shall afford the most convenient shelter and accommodation to passengers on the deck of the vessel crossing the Channel between France and England. The steamer is not to exceed in tonnage and draught the best vessels now in use between Folkestone and Boulogne, and the model must be on a scale of a quarter of an inch to a foot. The models, marked in cypher, are to be sent in to the Society of Arts' House, John-street, Adelphi, on or before November 1, 1869, with a sealed envelope, giving the name and address of the designer. The Council reserve the right of withholding either or both medals in case, in their opinion, the models sent in do not possess sufficient merit. The following particulars of the South-Eastern Channel steamers "Victoria," "Albert Edward," and "Alexandra," are given for the convenience of competitors, but it is not intended to confine the designs to them, except as to tonnage and draught:—Length between perpendiculars, 200ft.; breadth of beam, 24ft.; depth underside of deck amidships, 12ft. 6in.; draught of water, 7ft.; bow, clipper; stern, elliptic; rig, polacca with two masts, lug foresail, gaff mainsail, staysail, and flying jib; engines, oscillating; paddle wheels, 17ft. 6in. diameter; tonnage, 568 tons; speed, 17 miles an hour.

The condition of our cabs has not escaped the notice of this most useful society, and the Council offer the following medals for improved hackney carriages specially suited to the metropolis:—The Society's gold medal for the best and most convenient open hackney carriage for two persons. The Society's silver medal for the second best ditto. The Society's gold medal for the best and most convenient closed hackney carriage for two persons. The Society's gold medal for the best and most convenient hackney carriage for four persons, either opened or closed, or both. The Society's silver medal for the second best ditto. Lightness of construction, combined with adequate strength and durability, will be especially considered in making the awards. The awards will be made after actual trials of the carriages extending over a certain period. Communications describing the carriages must be sent to the secretary of the Society of Arts before January 1, 1870, the carriages to be sent to a place hereafter to be appointed. The Council also offer the Society's silver medal for the best instrument to be affixed to a cab or other hackney carriage for indicating the fare as between the passenger and the driver, whether by registering the distance travelled or otherwise, and which instrument shall also indicate, for the convenience of the cab-owner and of the driver, the total distance travelled during the day, and the total amount earned. The instruments competing, with full descriptions of their construction, to be sent to the Society's house before January 1, 1870. Competitors may, at their option, sign their communications, or may forward with them sealed letters containing the name and address of the writer. The Council reserve to themselves the right of withholding all or any of the medals in case none of the carriages or instruments possess, in their opinion, sufficient merit. In the trials of the several carriages, the small amount of vibration and noise will be duly considered by the judges.

SPECIFICATIONS OF PATENTS AT THE SOCIETY OF ARTS.

ATTENTION has been drawn by Mr. W. Lloyd Wise to the present unsatisfactory arrangement and condition of the specifications, indexes, &c., presented by the Commissioners of Patents to the library of the Society of Arts for the use of the public. It appears that the indexes have long remained uncut, so that it has been necessary for each reader to cut the leaves for himself, besides which many of the specifications are in very inconvenient situations, and cannot be picked out without considerable loss of time. If greater facilities were afforded to inventors for ascertaining what has been already protected we think that much would be done to obviate the objection now raised by "abolitionists" against patents, viz., that many inventions are re-patented. No doubt it was in a great measure with the view of having their publications easy of access to inventors and others in the Adelphi and its neighbourhood that the Commissioners gave these books to the Society, and it is to be regretted that so little has been done to carry out their good intentions. We hope there will be some real improvement now that public attention has been called to the subject.

MR. JAMES YOUNG, so well known in connection with the paraffin industry, has presented 10,000 guineas to Anderson's University, Glasgow, for the purpose of founding a chair of technical chemistry, and establishing bursaries, scholarships, &c. Mr. W. H. Perkin, F.R.S., who, it will be remembered, delivered a course of Cantor lectures before the members of the Society of Arts during the last session, has been appointed the first professor.

MACHINE FOR TIPPING PILE FABRICS.

BY MR. B. NORTON.

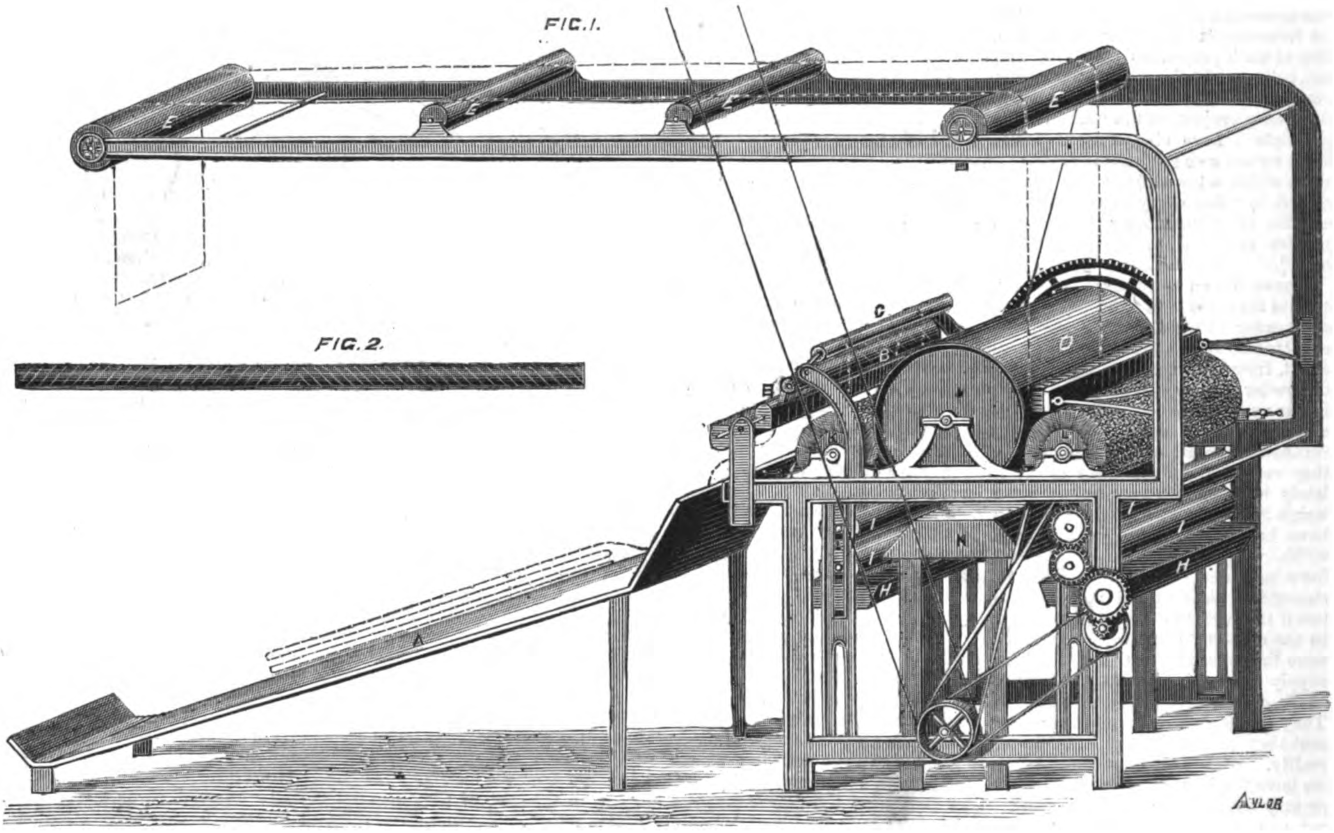

FIG. 1.
FIG. 2.

TIPPING PILE FABRICS.

THE invention illustrated in the accompanying engraving has for its object improvements in tipping pile fabrics. It has been patented by Mr. Benjamin Norton, of Nortonthorpe Mills, near Huddersfield, who applies colour, lacquer, resist, or discharge to the tips of the pile by means of circular revolving brushes. The pile fabric is led around a portion of the circumference of a drum with the pile outwards, and, whilst so supported, colour is applied to the pile by means of the circular revolving brushes.

Fig. 1 shows a perspective view of the machine. A is the scray upon which the piece is laid; B B B are fluted guide bars, the flutes of which incline from the centre to the ends in opposite directions, as shown separately in fig. 2, so that the cloth, as it passes over them, is extended to its full width, and the piece is also kept sufficiently tight as it is passing through the machine. C is a plain roller over which the piece passes. D is the large drum around which the cloth is led; on the under side of this drum is a guard of zinc or other material to prevent it being smeared with colour. E E are rollers over which the cloth is conducted as it passes forwards to a board on a table, where it is cuttled. If required, it can be hooked on to frames direct from the last roller E. H H are boxes containing colour. I I I I are regulating colour rollers supplying the brushes K L. The manner in which these rollers are driven is clearly shown by the engraving. M is a stationary brush carried at its two ends by pins passing through arms on the framing. This brush is set up towards the large drum D by means of screws. N is a guard to prevent any colour from the brushes or rollers falling under the machine.

When using the machine for tipping pile fabrics, the operator cuttles the piece straight and lays it upon the scray with the face downwards, and to the end of it he then attaches one end of a piece of canvas, and to the end of this three cords at equal distances, the canvas and cords being each of sufficient length to go through the machine. He then passes the cords through the machine, setting it in motion as soon as they have got under the large drum, and, when a portion of the canvas has passed the brushes, the boxes can then be supplied with colour or other liquid, so that the brushes may be fully saturated by the time the piece comes on to the large drum D. By this means, the piece is carried forward to the board, and is tipped in its progress. The cords and canvas are taken off as soon as they have passed the last roller E, and the canvas is attached again to the end of the last piece, and remains in the machine till it is required again.

The colour boxes are now lowered, and the brushes and colour rollers cleaned and replaced. The colour boxes can be raised or lowered as required, and are made of wood where the colour is used cold, but of iron or other metal where the colour is required to be kept hot. In this case, gas jets are applied under the box, or, in place of this, a box with a false or hollow bottom supplied with steam may be employed. The colour rollers are moved to or from each other by screws or other means, according to the quantity of colour required to be put on to the piece by the brushes. These rollers are of cast iron, hollow, with shafts through them, so that they can be heated by steam if required in order that the colour or other substance may be kept hot. Should the rollers not take up sufficient colour, they can be covered with india-rubber or other material to cause them to take up more.

In ordinary tipping, the first brush revolves in the same direction as the large drum carrying the piece, and the second one in the opposite direction. A little above this second brush is a stationary flat brush, the pressure of which is regulated by screws so that it shall just reverse the pile. In addition to these, more brushes, either circular or flat, can be employed, and they may be caused to move across or diagonally when the colouring matter or other liquid requires to be worked deeper into the pile. It is preferable to put the most colour on with the first brush, and for the others to brush it into the pile. The revolving brushes are driven at a surface speed of about eight or nine times the surface speed of the large drum, and the colour rollers at a surface speed of about twice the surface speed of the large drum. We may add that this machine is in daily use at the Nortonthorpe Mills, where it fully answers every expectation.

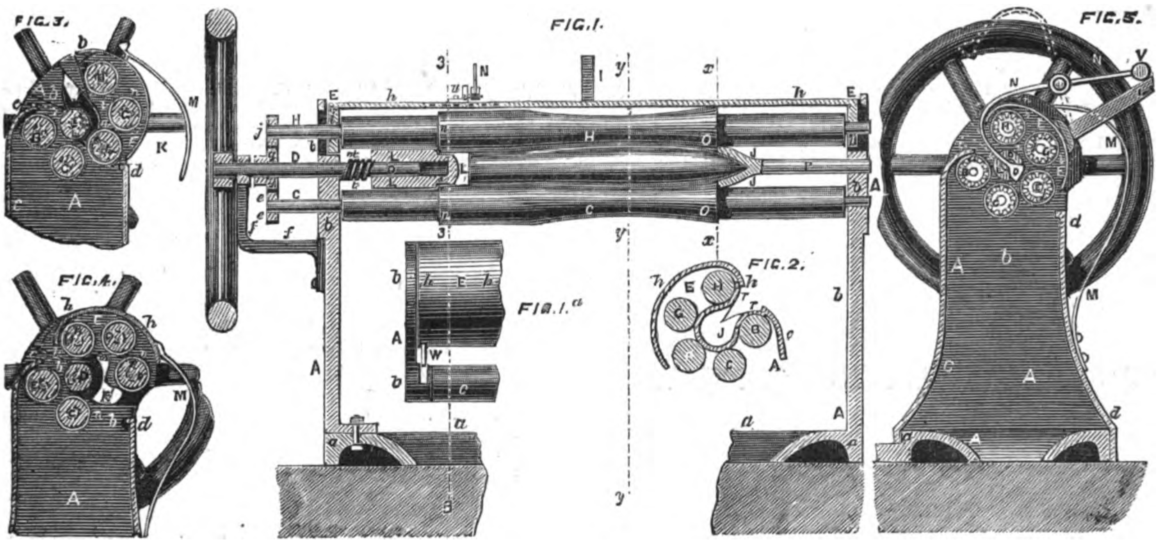
BALANCING HEAVY CYLINDERS.

THE shaking of heavy cylinders, grindstones, millstones, &c., when out of balance, depends upon and is caused by the irregularity of centrifugal force on the opposite sides of the wheel. That is, if the centrifugal force, or the sum of the tendencies to fly off in tangents to their arcs of revolution, possessed by all the particles on the lighter side, be represented by a, and that on the heavier side by b, the power to which the shaking is due will be represented by the expression $b-a$. Suppose, in a given case, b equals a pressure of 4,000lb. and a equals 3,750, the force with which the cylinder would be shaken would be 250lb., moving from one side of the axis to the other, and a vibration would be produced upon each interchange of place between the heavier and lighter sides, having for one of its elements of measure the ratio existing between the difference of the centrifugal forces of the opposite sides and the weight of the cylinder. If all the supports of such unbalanced wheels or cylinders were perfectly rigid and inelastic, no vibration would be felt, but the strain upon the axle journals and boxes would remain undiminished, so that greater strength of parts would be necessary in order to avoid breakages, and loss of power would accrue. In order that a cylinder may be perfectly balanced when in motion, it is necessary that the sum of the moments of the particles on one side (that is, the sum of their several weights multiplied into their several velocities) should exactly equal the sum of the moments of the particles on the other side, when the cylinder is running at any speed. This can never be more than approximately attained in practice. The writer, who has had considerable experience in balancing heavy cylinders, designed to run at high speeds, has found the following method the best. The cylinder being keyed upon its axle, as it is intended to run, is lifted by a tackle or crane, and lowered, so that each of its journals rests upon a stout steel straight-edge placed so that its upper surface is exactly level and parallel with its fellow. These straight edges should not only be so rigid as to suffer no sensible deflection from the weight of the cylinder to be balanced, but they should be very hard and as smooth as it is possible to make them; and great care should be taken to keep them free from indentations. The journals of the cylinder must also be round and polished in order to secure delicate action. All the friction is thus converted into rolling friction, and this is reduced to a minimum. The cylinder can now be loaded on its lighter side, or *vice versa*, until it will remain perfectly motionless when stopped in any part of its revolution. We have balanced heavy cylinders in this way until they would revolve by placing upon either side one twenty-thousandth of their weight. The method sometimes practised of suspending a cylinder by the centres of the journals is not sufficiently delicate. Either the lathe centres will be so forced in as to greatly increase friction, or there will be some play, so that the centre of suspension will be outside the centre of the axle. The latter makes no difference where the cylinder can roll, as on the steel straight edges, but when suspended from a point, it will certainly defeat the attainment of any great degree of accuracy.—"Scientific American."

AT a meeting held in Stirling it has been resolved to take steps to erect a monument to King Robert Bruce at Bannockburn.

MACHINE FOR MAKING CIGARS.

BY MESSRS. BRIGHT AND STONE,

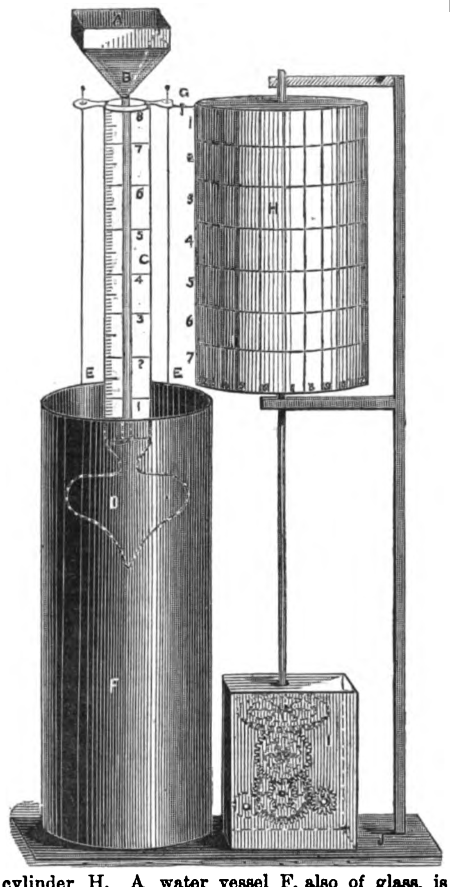


ON SELF-RECORDING ANEMOMETERS.

By M. Charles Rabache.

AT the recent meeting of the British Association, in Exeter, a self-recording rain gauge, invented by Mr. R. Beckley, of the Kew Observatory, and made by Messrs. Beck, of London, was presented in Section A; a paper was read, and a print containing its description was distributed.* Great and minute precautions have been taken in the invention and construction of this instrument, in order to render it as perfect as possible. In my opinion, however, it will not accurately record the quantity of rain fallen at a precise given time, and this for several reasons, amongst which are the following:—First, the tube, copper bottle, mercury surface, syphon, &c., will always retain a certain portion of the fallen water. Second, mercury being used to transmit to the recording cylinder the pressure of the water, will continually vary, not only according to the quantity of rain, but also conformably with its temperature and that of the ambient atmosphere, which, changing continually, will cause mercury to contract or expand accordingly, even when there will be no rain at all. In such changes of temperature, the pencil will indicate the fall of rain in dry weather. Warm or cold, summer or winter, rain will effect the mercury differently, and the same volume or weight of water will not be recorded by the same figure on the cylinder in every season. Third, the action of the syphon causes an intermittence, and its emptying and that of the bottle will never be instantaneous and complete. The rain falling while the syphon is in action will not be recorded. Fourth, the instrument being constructed in oxidable metals, oxidation is sure to take place in time. Fifth, the friction rollers will also more or less affect the instrument. Being complicated, it must, consequently, be expensive.

These defects suggested to me the invention of a new instrument, of which the following is a description, reference being had to the accompanying engraving. My instrument is of glass, consequently, is not oxidable. It is self-recording, and gives at the same time with the greatest precision three indications—weight, volume, and time. One of its parts controls the other. It can be made of any size, and adapted to different purposes. A funnel-shaped receiver A, of any calculated surface, has a long and narrow tube B, curved at right angles at its lower extremity *o*, to take the water down to the bottom of the meter, and deliver it horizontally, so as to avoid a pressure which would act on the instrument. The meter C is composed of a properly graduated glass tube, every degree of which represents in volume one cubic centimetre, and in weight one gramme of water. Each degree is divided into tenths, indicating the tenth part of a centimetre or one millimetre of water. The lower part of the meter is formed of a float D, which makes it float in water up to the flotation point *o*. At the top of the tube is a metallic circle, into which pass two pins or slide rods E E to prevent oscillation. On the right side is a pencil G supported by a flexible metallic spring. This pencil presses slightly against a



cylinder H. A water vessel F, also of glass, is filled with water; its depth is proportioned to the length of the meter. I is a clockwork arrangement which can be placed at will, the spindle of which, being vertical, gives motion to the recording cylinder H at the rate of one degree per hour, or one revolution in a day. The circumference of the recording cylinder is horizontally graduated in degrees, corresponding with those of the meter. Longitudinally it is divided into twenty-four parts indicating the twenty-four hours. The whole rests upon a stand J. The entire instrument may be cased in a mercury air-tight case if thought proper. In case a syphon should be found useful, it can be adapted to the meter.

The action of the instrument requires no long description. The rain fallen in the funnel of a known surface is directed into the meter in *o* flotation point, its weight deepens the meter in the water contained in the water vessel in a proportion or degree indicated by the rule which, at the same time, indicates the volume. Therefore, by merely looking at the instrument in water, we see the quantity and weight of rain fallen. As the meter deepens in the water, the pencil placed at its top descends, and makes a trace on the recording cylinder. The heavier the rain, the faster the meter deepens; the rule or scale of the recording cylinder being the same as that of the meter, they both give the same indication, and control one another. The meter only shows the quantity and weight of water fallen on a given surface, but it does not indicate the time of the fall. This is shown by the recording cylinder. As long as there is no rain falling the pencil remains at the same height; the recording cylinder turning regularly on its axis, the pencil mark is a horizontal line extending to as many degrees as there are hours without rain. As soon as rain falls, the pencil moves downwards, and every minute, second, part of a second, &c., the quantity of rain falling is instantly recorded in pencil writing on the cylinder. Supposing the surface of the receiver to be 1,000 square centimetres, a fall of rain of one millimetre in thickness collected in the mete r wil fill one centimetre of it; and if of one centimetre in thickness, it will deepen it ten centimetres. Instruments with small receivers will suit for recording heavy rains, whereas large receiver ones will do better for minutely recording light rains. —Marchain, Somme, France.

* An illustrated description of Mr. Beckley's Anemometer will be found at page 24 of our present volume.

MACHINE FOR MAKING CIGARS.

THE machine represented in the annexed engraving is designed to manufacture cigars complete. It is to roll the filling, to wind the inner and outer wrapper around it, to form the point, and to cut off the end so as to form a perfect cigar. It is the invention of Mr. Bright and Mr. Stone, of New York, and has been patented in England. In our engraving fig. 1 represents a vertical longitudinal section of the machine; fig. 2 is a detail vertical transverse section taken on the line *x x*, fig. 1; fig. 1a is a detail plan view of the same; figs. 3 and 4 are vertical transverse sections taken on the line *y y*, fig. 1; fig. 5 is a vertical transverse section taken on the line *z z*, fig. 1. A represents a metallic frame consisting of a slotted bed plate *a*, of two uprights *b b* at the end of the bed plate, of a front-face plate *c*, and of a rear plate *d*. The front and rear plates extend from between the two uprights and to the bed plate. In the end pieces, *b b* are the bearings of two horizontal non-elastic rollers B and C, which carry each at one end, outside of the frame, a small pinion *e*, as seen at fig. 1. D is a short horizontal spindle having its bearings in one of the uprights *b* and in an arm which projects from it. The inner end of the spindle extends about an inch beyond the inner face of the upright *b*. The spindle D carries a toothed wheel *g*, which gears into pinions *e e*, and carries a flywheel and a crank or pulley for the purpose of receiving motion. E is a frame consisting of a long curved plate *h* and two vertical end pieces *i i*, which rest with their lower edges on the endpieces *b b*. In the end pieces *i i* of the frame E are the bearings for three horizontal non-elastic rollers F G and H. The axes of these rollers project through one of the perforated uprights *b*, and carry pinions *j j* of the same size as the pinions *e* seen in fig. 5. The lower edges of the end pieces *i i* are provided with two rounded projections *k l*, fig. 4, and between them is a rounded recess *m*. Corresponding to them are formed on the shoulders of the uprights

b rounded recesses k' l', and between them a rounded projection m', fig. 4.

The frame E has a projecting handle I by which the frame can be swung so as to turn around the projection k or l as may be desired. The upper part of the front plate c is bent somewhat over the roller B, whilst that of the back plate is bent as seen in figs. 3, 4, and 5. When the frame E is so set that its edges k l m all come in contact with the parts k' l' m' of the frame A, the pinions of its rollers F G H will all be in gear with the wheel G, as seen in fig. 5, otherwise they will not be in gear. Each roller is provided with two shoulders n o between the uprights of the frame A; the shoulder n being near the spindle D, the other, o, being near the opposite upright b, as seen at fig. 1. Between these shoulders, each roller is formed with a curved side, which is thinner in the middle than near the shoulders, so that between the fine rollers a cavity is formed resembling the shape of the cigar. Opposite to the spindle D, and in a line with it, is fitted through the upright b a pin P, on which the point-former or header J is secured. This header is a metal plate of the shape of an open cone, with two projecting lips r r which fit under the plates c and h, as seen in fig. 2. These lips prevent the header from turning. The inner end of the header abuts against the shoulders o of the rollers. Upon that portion of the spindle D which projects from the inner side of the upright B, is fitted a cylindrical block L which has a shoulder s. Between this block and the upright b is interposed a spring t, which serves to push the block forward so that its shoulder s is always in contact with the shoulders n of the rollers, whilst, at the same time, the spring will allow the block L to yield to pressure against its inner end. A spring M is fastened to the frame A to hold the frame E in any desired position, either by mere friction or by fitting in notches formed in the plate h. N is a curved bar pivoted to an adjustable ear u, which is fitted upon the plate h. One end of this bar has a weight V, whilst the other end carries a knife O, as seen at fig. 5. The weight keeps the bar N always in the position shown by dotted lines in fig. 5, that is, out of the way; but the bar can be swung so as to bring the knife between the rollers to sever anything held between them.

In working this apparatus, the frame A is set up so as to be immovable. The frame E is, by means of the handle I, swung back so as to swing around the projections k; thereby the rollers B and H are brought far apart, as in fig. 3, to allow the insertion of the tobacco for forming the filling between the rollers. The frame E is then swung forward into the position shown in fig. 5, to bring all rollers in gear with the spindle. The rollers are then all revolved, and roll the filling into the desired form. The follower L will yield to the tobacco if there should be so much as to make the cigar longer than required. The inner and outer wrappers are then, with their ends, inserted between the rollers B H, and will be wound around the cigar. The header J causes the required form of point to be produced on the cigar. When the cigar has been completely rolled, the knife is brought down to cut the broad end off and to trim it so that the cigar will be of a certain desired length. To vary the lengths of the cigars, the ear u is adjustable on the plate H, as indicated in fig. 1. The cigar is now complete, and, by swinging the frame E forward, as in fig. 4, to bring the rollers C and F apart, it will be discharged from between the rollers, and will drop through the slot of the bed plate a into a receiver. By making one of the uprights detached from the plate a and face plates c d, the machine is so arranged that the parts can be separated so that the rollers of various kinds of cigars, as well as headers and followers of suitable form, may be inserted. From the front of the frame E project tongues W fitting into corresponding recesses of the frame A, as seen in fig. 1 a, to keep the frame E steady when the machine is in operation.—"Tobacco Trade Review."

OVERHEATING OF FURNACE CROWNS AND OTHER BOILER PLATES WHEN COVERED WITH WATER.

By Mr. L. E. Fletcher.

(Continued from page 211.)

Another very similar case of failure of furnace crowns was met with in May, 1866. It occurred in the neighbourhood of London to a Cornish boiler fed with the New River Company's water. This boiler I was informed had failed at the furnace crowns, and repeated repairs been resorted to. These, however, had such little effect that one boiler after another had been laid down till some three or four boilers had been ruined in the course of three years; while one of the boilers had received a new flue-tube. Added to this, experiments had been tried by altering the steam dome, and, altogether, the owner informed me the affair had cost him £700. Disheartened with these repeated failures, he was persuaded to exchange the internally-fired boiler for an externally-fired one with a couple of return tubes running through it, which he had just laid down at the time of my visit. On making an examination of the boiler I found that it contained a good deal of fine floury deposit of a light colour, and that the feed water was heated by the injection of the exhaust steam from the high-pressure engines, so that the grease from them passed through into the boiler. I called the owner's attention at once to these facts, and explained to him that these were the causes of all the trouble he had experienced. He urged by way of objection that prior to the last three years the boiler had worked for a considerable time with the same water and with the feed heated by the exhaust steam, without giving trouble, and therefore argued that the fault could not be with the water or with the grease discharged from the engines. This objection appeared at first sight difficult to meet, but on inquiry it was found that about three years before then the work became too severe for the engine, when its power had been doubled by the addition of a new cylinder, which gave the boiler more work to do and necessitated its being more severely fired. This at once made the whole matter plain. The tendency had existed all along, but had not been developed till the fires were pressed.

The following is an analysis of the deposit in question:—

Carbonate of lime	73·87
Carbonate of magnesia	4·59
Oxide of iron and alumina	7·07
Organic matter	3·15
Sand silica alumina	11·32
	100·00

N.B.—This was a fine dry powder of a slate colour, difficult to wet with water.

It will not escape observation that this floury deposit contained as high an amount of carbonate of lime as 73 per cent., and, simple as it appears, it was through the presence of this fine flour or dust that the four boilers referred to above were ruined, and the expenditure of £700 incurred. In the new boiler a good surface blow-out apparatus was adopted, and the boiler was frequently blown out at the bottom as well as from the surface of the water. This proved sufficient to remove the difficulty, though the credit was wrongly given to the change from the internally-fired boiler to the externally-fired one. Externally-fired boilers are affected by this description of feed water as well as internally-fired ones, which will be seen from the next case of injury.

A third case was met with in June, 1867, at a colliery in the neighbourhood of Ruabon, North Wales. In this instance six new plain cylindrical egg-ended externally-fired boilers failed within six weeks after they were set to work, giving way at the plates over the fire. These boilers were 5ft. 6in. in diameter, 36ft. long, made of plates ⅜in. in thickness, and worked at a pressure of 40lb. per square inch. The owners threw the blame of the failure of these boilers on the makers, attributing it to the quality of the plates or workmanship, and consequently a dispute arose, and I was requested to make an examination. On doing this I found that the plates over the fire were of Low Moor iron and of good quality, and that the fault did not rest with the boilers but with the feed water, which formed, as in the previous instance, a fine floury deposit, consisting to a great extent of carbonate of lime, while it was heated by the exhaust steam from the engines and thus charged with grease, in consequence of which, as in the previous cases, the plates over the fire had been overheated and bulged down out of shape, while, in addition, leakage had taken place at the seams of rivets. The manager was unwilling to accept so simple an explanation of the difficulty, though he had previously received a similar opinion from another engineer and been advised that he must either change the feed water or give up heating it with the exhaust steam, so as to prevent the introduction of grease to the boilers. Though ridiculing the recommendation, he had nevertheless diverted the exhaust steam from the feed water, when he found that the result justified the explanation given and the remedy proposed. Time showed that overheating did not recur, and the boilers worked on without further trouble.

The following is an analysis of the deposit formed within these boilers, and which, I believe, was taken from them before the arrangement for heating the feed by the exhaust steam was given up, so that at that time grease was admitted:—

Carbonate of lime	75·26
Sulphate of lime	10·02
Carbonate of magnesia	8·78
Oxide of iron and alumina	0·47
Insoluble matter (sand, &c.)	2·68
Organic matter	2·79
	100·00

N.B.—This sediment was a white powder and smelled of tallow. By digestion with ether some grease was extracted and collected.

The following is another analysis of the deposit taken from these boilers subsequently to the last specimen, and after the practice of heating the feed water with the exhaust steam had been discontinued, when the boilers were fed with cold water:—

Carbonate of lime	84·10
Sulphate of lime	2·25
Carbonate of magnesia	8·73
Oxide of iron and alumina	1·41
Insoluble matter (sand, &c.)	1·98
Organic matter	1·53
	100·00

N.B.—The organic matter does not contain grease.

It will be observed the grease was detected when the feed water was heated by the exhaust steam but not after that practice was discontinued.

In addition to the above, further analyses were made at a later date both of the fine floury deposit and of the scale:—

FLOURY DEPOSIT.

Carbonate of lime	80·00
Sulphate of lime	6·08
Carbonate of magnesia	12·44
Oxide of iron and alumina	0·98
Sand, &c.	0·5
	100·00

SCALE.

Carbonate of lime	77·40
Sulphate of lime	9·52
Carbonate of magnesia	10·90
Oxide of iron and alumina	1·22
Sand, &c.	0·96
	100·00

The following is an analysis of the water with which these boilers were fed:—

The total solid matter left on evaporating a portion of the water amounted to 40·15 grains per gallon. This consisted of—

	gr. per gal.
Carbonate of lime	23·75
Sulphate of lime	1·57
Sulphate of soda	4·33
Common salt	2·63
Carbonate of magnesia	5·18
Organic matter and loss	2·69
	40·15

N.B.—The carbonates of lime and magnesia are kept in solution by the presence of free carbonic acid. If this is neutralized by the addition of lime, a portion is precipitated. By this means nearly one-half the total matters in solution may removed. Also in boiling the water, before evaporation commences, a portion is precipitated.

From the above analyses the high proportion of carbonate of lime will be seen in each case:—

		per cent.
Analysis No. 1 gave—	Carbonate of lime	75·26
„ No. 2 „	Carbonate of lime	84·10
„ No. 3 „	Carbonate of lime	80·00
Mean result		79·78

From this it appears that the mean result was nearly equal to 80 per cent. of carbonate of lime contained in the fine floury deposit.

It should be added that at the same colliery there was another range of plain cylindrical externally-fired boilers, which had been working for a number of years, without failing as the new ones had done. The manager, therefore, pointed to this fact in support of his view that the new boilers were at fault, and not the feed water, since the feed water appeared to him to be as good in one case as in the other. To settle this question an analysis was made of the water with which the old range of boilers were fed, as well as of the deposit formed within them, in order that a comparison might be instituted, when the following was found to be the result:—

SEDIMENT.

Carbonate of lime	22·0
Sulphate of lime	63·78
Magnesia	14·07
Oxide of iron and alumina	0·09
Sand, &c.	0·06
	100·00

SCALE.

Carbonate of lime	10·17
Sulphate of lime	72·94
Carbonate of magnesia	15·89
Oxide of iron and alumina	0·63
Sand, &c.	0·37
	100·00

The following is an analysis of the water:—

A portion of the water, evaporated to dryness, left a residue amounting to 90·3 grains per gallon. This contained—

	gr. per gal.
Carbonate of lime	0·15
Sulphate of lime	16·93
Sulphate of soda	51·55
Common salt	2·93
Carbonate of magnesia	17·11
Magnesia	1·22
Organic matter and loss	0·41
Total	90·30

N.B.—As this water is concentrated by evaporation it becomes alkaline.

The addition of lime gives a precipitate amounting to nearly one-third the total matter in solution.

Boiling the water causes no precipitate. There was a deposit of organic matter at the bottom of the jar which contained the water.

The results of the analyses of the feed waters of the new and old ranges of boilers, as well as of the sediment, will be the more easily compared on reference to the following table:—

NEW BOILERS.	Percentage of carbonate of lime in fine floury deposit.	Grains of carbonate of lime in a gallon of water.
Which failed after six weeks' working	79·78	23·75
OLD BOILERS.		
Which worked for years	22·0	0·15

From this table it will be seen how different were the characters of the waters by which the two ranges of boilers were supplied, and how much more carbonate of lime was contained in the one that fed the new boilers which failed after six weeks' work, than in the one which fed the old boilers which worked on for years, while it corroborates the view that the failure of the new boilers was not due to their material or workmanship, but to the fine floury deposit formed by the feed water.

(To be continued.)

IMPROVED PISTON FOR STEAM AND OTHER ENGINES.

By Mr. T. H. Martin.

At the annual meeting of the Miners' Association of Cornwall and Devon, recently held at the Polytechnic Hall, Falmouth, Pendarvis Vivian, Esq., M.P., in the chair, the following important and interesting paper, by Mr. T. H. Martin, of the Morfa Copper Mills, Swansea, was read, it being selected from amongst several other papers which had been sent in for discussion:—

The piston being the medium by which the power of the steam is exerted and transmitted through the rod to the work to be performed, it naturally forms one of the most important parts of the steam engine, consequently the duty of the engine, in a great measure, depends on the efficiency of its work. Pistons are of various constructions, but all may be classified under two heads, viz., those for single-acting and double-acting engines. In single-acting the steam is admitted on one side of the piston only, the reverse side being generally hollowed out; whilst in double-acting engines the steam is admitted on both sides alternately. It is not material in the construction of a piston whether the engine is condensing or non-condensing.

I propose to refer to each class of piston in the following order:—First, to those for single-acting pumping engines; second, to those for double-acting engines. I purpose briefly describing the form, and to point out the disadvantages attached to pistons that are generally applied to single-acting engines. They are variously constructed, as before remarked, particularly those parts—*i.e.*, the rings—which are brought into rubbing contact with the cylinder. These are generally made parallel or bevelled; they are invariably packed behind with greased gasket, india-rubber, lead, or with patent packing, for the purpose of pressing them against the cylinder, or to make them steam-tight. Goodfellow's bevelled rings, fitting between flanges of piston, with a narrow wedge-like ring behind, are sometimes used; also Ramsbottom's small square rings, which are fitted into the periphery of the piston. Some use Stephenson's method, consisting of rings with steel springs, and bolts for tightening; others adopt segments with wedges. These and various other methods have been applied from time to time for producing continuous steam-tight pistons, but hitherto without success. Having briefly described a few of the varieties of pistons in use, which may be classified under two heads, viz., packed and spring, I will now point out the disadvantages attached to each. Packed pistons are those which are packed with gasket, &c. They continue steam-tight for a very short period only, and even when in that state produce enormous friction, so much so that the engine is deprived of much of its power. The friction is also the same in the "outdoor" as in the "indoor" part of the stroke; this is unnecessary, for the piston is not required to be steam-tight in going the "outdoor" part. Spring pistons are those which are provided with steel springs, bolts, wedges, &c. They quickly (through wear and tear, heat, &c.) lose their elasticity, producing results precisely the same as in packed pistons. The steam in escaping is not only a loss of power in itself, but on its escape to the other side of the piston, which is open to the condenser, partially destroys the vacuum.

The following may be taken as showing the principal disadvantages attached to pistons now in use. First, when steam-tight, increased friction from being newly packed, and unnecessary friction when going the outdoor part of the stroke. Second, steam, in escaping, is a loss of power in itself. Third, in its escape it considerably decreases the vacuum, which is also a loss of power; and, last, the great expense of labour and materials, &c., in packing, with the necessary delays occasioned therefrom.

It is an admitted fact by all engineers who have at all considered the matter that the Cornish pumping or single-acting engine is capable of developing a far greater amount of duty than any other class of engine when under similar conditions; and it is with the view of an increased development of power in this type of engine that I suggest the introduction of steam-tightening pistons. The good results obtained from trials made prove that the great advantages they possess result from the principle on which they are constructed, and I feel assured that a trial only is necessary to convince anyone of their superiority over the present method. Steam-tightening has been adopted for many years past for locomotive and other small engines, but from the imperfect method of admitting the steam, and defective construction of the piston and rings, they have in most cases been abandoned.

The forms of piston I propose for single-acting pumping engines are in figs. 1 and 2 in accompanying engraving. Fig. 1 is for a piston where

FIG. 1.

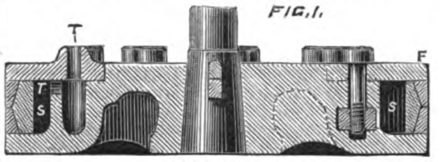


FIG. 2.

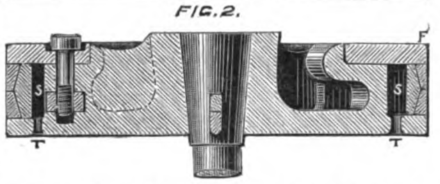

steam is admitted on top, as for the ordinary single-acting pumping engine. Fig. 2 is for a piston where steam is admitted under, for single-acting of the inverted type.

The piston may be described thus:—The form of the body does not vary much from those now in use, and may be fitted to the rod in precisely the same manner. The difference is in the rings, which are three in number, and are well fitted to each other, ground and scraped to flange of piston, and to lugg ring. To allow for the wear of the outer rings, the inner one is made a little larger in diameter, and a piece is cut out of its circumference to make it fit at the back of outside rings; a space S (a little larger than that which is generally allowed for packing in packed pistons) is provided for steam which is admitted through holes T, arranged as in figs. 1 and 2. By this arrangement, when steaming, a continual pressure, equal to the working pressure, acts against the inner surfaces of the inside ring F, which presses the others against the cylinder in such a manner as to effectually prevent any escape of steam from one side of the piston to the other.

The advantages gained by the above piston over that of the ordinary construction are:—Economy in fuel; increased power from less friction (for when in equilibrium the latter would be very trifling); the saving of steam that would otherwise escape, thereby increasing the vacuum; effecting a great saving in labour, and materials for packing, and also in preventing delays. Seventy-five per cent. of the old pistons could be easily converted into steam-tightening on this principle, and at a very trifling expense.

Referring, secondly, to pistons for double-acting engines. Those generally used are, as before described, for single-acting engines, and any advantages with regard to increase of power and economy in fuel which may be derived from steam-tightening in that type of engine would be double when applied to engines of this class. The method for admitting steam behind the rings, as shown in figs. 1 and 2, would necessitate the piston being provided with two sets of steam-tightening rings, one for each side of the piston, also with two lugg rings, with bolts, nuts, &c., and then only one set of rings would be steam-tightening at the same time, the other being drawn inward by vacuum, when from one side or the other a continuous rattling of the rings would ensue, thus producing the following objections for steam-tightening the pistons of double engines, on the principle of those for single-acting:—First, the piston would be required more than twice the depth it need be. Second, the continuous noise consequent from rings being acted on alternately by steam and vacuum.

To obviate these objections, and to use only one set of rings, I have designed a piston as seen at fig. 3 in the accompanying engraving, and for which letters patent have been granted.

FIG. 3.

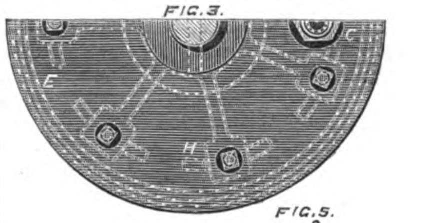

FIG. 5.

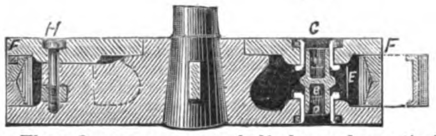
FIG. 4.



These figures represent a half plan and a vertical section of the piston of a 36-inch horizontal condensing engine, which has been working for the last six months night and day (Sundays excepted) effecting a saving in fuel quite 15 per cent., with 10 per cent. additional power. The cylinder was opened a few days since merely for inspection of piston, and to my great satisfaction scarcely the slightest amount of wear was discovered, either in valve or rings, it being steam-tight in all parts of the stroke. The vacuum has been improving from its commencement, and may now be considered as almost perfect; this has arisen no doubt from the rings and cylinder becoming better fitted to each other.

The invention consists in the introduction of a valve C in the body of the piston having chambers B formed in its interior at each end. Around the sides or walls of these chambers, and communicating with the interior of the piston, are any convenient number of ports or openings D. These, as the valve is forced to and fro alternately, communicate with the interior of the piston E, allowing the steam to press or tighten the rings F against the sides of the cylinder. H are bolts for securing the lugg ring. To prevent "blowing through" while the valve is in motion, the portholes are so constructed that one side will have closed before the opposite one opens. The valve or valves may be made either single or double, and placed opposite to each other, or otherwise as may be found most convenient.

The advantages gained by this invention comprise the following—the economising the entire cost of the springs, bolts, and nuts used in the construction of ordinary spring pistons, and with the common packing with yarn, vulcanised india-rubber, and lead. There will be a great saving also in labour and fuel, prevention of delays in opening cylinders, &c., and the loss of power to the engine on account of the springs, rings, and packing losing their elasticity.

After reading the paper, Mr. Pearce remarked that he could bear testimony to the efficiency of the new description of pistons, having seen them in engines at Swansea.

We understand Mr. Martin's improved piston has been tried and found to answer with the most marked success. Mr. Wm. Williams, of the Millbrook Ironworks, Swansea, says "The construc-

tion of the piston is very simple, and it does its work very efficiently, and I firmly believe it will work much more economically than a piston fitted with steel springs in the ordinary way." Mr. William Williams, engineer, of the Hafod Copper Mills and Foundry, says, "In my opinion, it is the most effectual working piston out." Mr. John Burgess, of the Perran Foundry, Cornwall, says, "The action of the valve when the piston reaches each end of the cylinder is perfect, as could be distinctly heard by listening close to the cylinders whilst at work. The vacuum obtained was the best I ever saw obtained in any engine; in fact, it appeared quite perfect, whilst a great advantage must be obtained by the pressure of the piston against the cylinder being constantly in proportion to the load. That this pressure is not at any time too great is proved by the large saving effected in coals. I was much pleased with its action." Mr. Thomas White, of the Lliw Forgery, Swansea, says, "Although, for the last twenty years, I have had great experience in both marine and stationary engines, I have never seen one so simple and effective, or less liable to get deranged, neither have I ever seen such a good vacuum as your gauge registered." Many other testimonials bespeak the value of Mr. Martin's patent, and, as a mechanical improvement in the right direction, there are ample grounds for believing that it will prove a practical success and quickly find its way into general use.

GOVERNMENT STORES.

THAT wonderful clerk in the War Office who struck out the sublime idea of taking the Sunday's pay from the gunnery serjeant-instructors and the serjeant-instructors of gymnasia, for which idea we understand he is to be permitted to take rank beside Cole, C.B., should cast his inquiring eye over the mode in which government stores are sometimes disposed of. We, "United Service Gazette," have heard strange stories of the way in which soldiers' coats are sold to the few brokers who have the privilege of the *entree* to the auction, and the fabulous sums that are afterwards divided at the "knock-out." There has been, we are credibly informed, as much as £140 per man divided on those occasions. When we know that overcoats lined with woollen all through, and almost new, go for 6s. each, and Highland beavers, with their ostrich plumes, and of which the first cost was £3 19s. each, for 8s. 6d., this liberal division of "swag" is not surprising. The ingenious expedient by means of which the auction-room is made select has also come to our knowledge. No intending purchaser is admitted until he has first paid £5 for a catalogue, the amount to be afterwards deducted from the price of his purchases. It is not difficult to imagine how much this ingenious expedient must increase the publicity of auctions which are ordained to be "public" by act of parliament.

TO CORRESPONDENTS.

THE MECHANICS' MAGAZINE is sent post-free to subscribers of £1 1s. 8d. yearly, or 10s. 10d. half-yearly payable in advance.

All literary communications should be addressed to the Editor of the MECHANICS' MAGAZINE. Letters relating to the advertising and publishing departments should be addressed to the publisher, Mr. R. Smiles, MECHANICS' MAGAZINE Office, 166, Fleet-street, London.

To insure insertion in the following number, advertisements should reach the office not later than 5 o'clock on Thursday evening.

We must absolutely decline attending to any communications unaccompanied by the name and address of the writer, not necessarily for insertion, but as a proof of good faith. ED. M. M.

Advertisements are inserted in the MECHANICS' MAGAZINE, at the rate of 6d. per line, or 5d. per line for 13 insertions, or 4d. per line for 26 insertions. Each line consists of about 10 words. Woodcuts are charged at the same rate as type. Special arrangements made for large advertisements.

MR. R. R. EDWARD.—Your communication should have been directed to the editor, and not to Mr. J. Passmore Edwards, whose connection with the MECHANICS' MAGAZINE ceased at the end of 1867. Directed as it was it has failed to reach our hands.

H. K.—The above observations apply to the remarks in your letter, and we would call the attention of our correspondents generally to the notice which always appears on this page, that literary communications are to be addressed to the editor, and letters relating to the advertising and publishing department to the publisher. Letters relating to other matters may be addressed to the proprietors, Messrs. Robertson, Brooman, and Co.

RECEIVED.—R. S.—L. P. S.—J. N.—B. D.—J. H.—S. and A.—R. M.—G. H. W.—T. H. M.—S. A.—E. M.—R. R.—A. F. W.—L. C.—H. J.—F. M.—R. G. S.—F. O.—S. J.—W. L. W.—H. V.—R. I. W.—B. F.—H. T. B—R. D.—J. B. and Co.—G. W. H.—S. E.—J. N.—B. J.—R. H.—F. E. C.—T. B.—L. S. G.—H. M.—J. C. P.

A WOMAN named Godzielska has just died at Posen, aged 99 years. She formerly served as vivandiere in the armies of Napoleon I., and went through the campaigns of Spain, Russia, and Germany.

Naval, Military, and Gunnery Items.

IT is with regret we have to announce the wreck of the Peninsular and Oriental Company's fine steamer the "Carnatic," involving the loss of several lives, with the whole of the specie and cargo on board. The calamity occurred on the 13th inst., off Shadwan, in the Gulf of Suez.

THE remainder of the inmates of Greenwich Hospital who have agreed to accept special pensions under the terms of a recent Act, have left the establishment, and the building will shortly be appropriated for the purposes of a national naval collection, under the direction of the Lords of the Admiralty.

THE Lords Commissioners of the Admiralty have notified that the Royal Naval School, New-cross, will, under the new regulations respecting naval cadets, receive in future four competitive, instead of two actual nominations. These are in addition to the nominations for clerks' assistant and navigating cadetships already placed at the council's disposal.

THE "Victoria and Albert," Royal yacht, having undergone extensive alterations and repairs, was taken out of No. 8 dock and placed in the steam basin at Portsmouth, on Friday. The dock thus vacated will be available for the reception of the partially constructed keel of the "Devastation," armour-plated turret ship, which is to be built at Portsmouth.

WE are informed that it is the intention of the Admiralty to hold a medical examination for the entry of naval cadets and navigating cadets at Somerset House for the future, a board being summoned by the Director General for the purpose. This (says the "Lancet") is probably only a step towards the whole of the admissions to the service being decided by a medical board, instead of a single medical officer, as at present.

THE Public Works Loan Board have issued a return which shows that in 1868 they decided on making the following harbour loans at 3½ per cent. interest:—Carnarvon, £10,000; Great Yarmouth, £27,000; Isle of Man (Douglass), £40,000; Tyne, £25,000; Wear, £25,000. The following applications were refused:—Bray, Bristol and Portishead Pier and Railway, Dublin Port and Docks, Drogheda, Wicklow.

ON the 12th inst., the 15th anniversary of the death of Blucher was celebrated with some solemnity at Krieblowitz, where his body lies buried. During the day the tomb was visited by large numbers of people, and at six o'clock in the evening the riflemen marched with music to the spot. A poem in honour of the warrior was then recited, a cheer given for his Majesty the King of Prussia, and the crowd dispersed singing patriotic songs, which were frequently interrupted by salutes.

THE English Government has presented the chief pilot of the North German navy, who served on board the "Minotaur" during her visit to Wilhelmshaven, with a splendid telescope and double eyeglass, which bear the following inscription:—"Presented by the Lords of the Admiralty to Herr J. P. Hanke, Chief Pilot of the North German navy, in commemoration of the visit of H.B.M.S. 'Minotaur' to Wilhelmshaven, on the opening of that port by H.M. King William of Prussia, June 17, 1869."

MR. KEY, of Kirkcaldy, recently launched from his building yard at Abden, near Kinghorn, the largest iron ship ever built on the Forth. The vessel is named the "Abden." She is the ninth steamer Mr. Key has launched since he commenced operations at Abden, and is the finest as well as the largest. She is 320ft. in length, 38ft. in breadth, and 28ft. in depth. Her engines, which have been made by Mr. Key, are surface-condensing, on the horizontal principle. They are 500-horse power nominal and 1,700-horse power indicated, and are calculated to give a speed of 14 knots an hour. The diameter of the cylinders is 70in., and the stroke is 38in. Steam is generated in four tubular boilers, with four furnaces each.

A 13-INCH sea service mortar, of 5 tons weight, has been ordered to be converted upon Major Palliser's plan into a 9-inch rifled mortar of about 6¼ tons weight, to fire the 9-inch service rifled shell, which contains a bursting charge of 18lb. of powder. The bore of the mortar will be elongated to about 4ft. 6in.; and a range of about 7,000 yards is expected to be obtained from a charge of 20lb. of powder. Some further experiments are being carried on with two 10-inch shell guns, which are being converted respectively into an 8-inch and a 7-inch rifled gun, in order to determine the most suitable calibre for the conversion of cast-iron 10-inch shell guns. The whole of the 212 8-inch guns converted into 6·3-inch rifled guns by Sir William Armstrong and Co. have been passed into the service, and 200 more are in course of conversion in the royal gun factories. It is probable that a considerable number of guns will be converted next year for land defences, the whole of the above 437 guns being for the navy.

Miscellanea.

AT a recent meeting of the Glasgow police board, Messrs. Honeyman and Drummond obtained the sanction of the authorities to run steam omnibuses, by way of experiment, on the streets of Glasgow.

THE opening of the railway from Monaco to Mentone will take place towards the end of October next; the laying of the rails has been commenced at both ends and is rapidly progressing.

THE total cost of the Customs establishments in the United Kingdom during the year 1868 was £792,221 16s. 7d. The amount of Customs duty collected was £22,693,507.

THE Prussian Bible Society in Berlin has distributed since its foundation in 1814 more than three millions of copies of the Holy Scriptures. In the year 1867 alone, the number was 90,000.

THE statue of Mirabeau, by M. Trupheme, which appeared in the present year's exhibition at Paris, has been presented by the Government to the Palace of Justice at Aix, in which town Mirabeau was born.

THE exhibition building at Pilsen, in which the machinery had been deposited, was blown down by a violent storm from the west on the evening of the 13th inst. It is feared that the loss will be very heavy.

THE Bengal opium crop of 1868-9 has produced 46,894 chests, in place of 58,000, as was at one time expected. It is therefore thought there will be no difficulty experienced in bringing forward 48,000 chests for sale in 1870.

DURING the past year the quantity of silkworms' eggs exported from Japan amounted to 2,195,651 cards. Of this number 800,000 have been sent to France, Spain, Turkey, Persia, and other countries, and the remainder to Italy.

THE Belgian Minister of Public Works has just organised a system of trains for the benefit of the workmen who live out of Brussels. The payments are to be made weekly and in advance, and the rates vary from 1f. 20c. for one league to 2f. for twelve miles for the six days.

LUIGI POLETTI, the most celebrated Italian architect, has just died at Milan, aged 77. His last work was to direct the construction of the church of St. Paul at Rome, which the Pope desires to have terminated by the period fixed for the opening of the Council.

THE next ordinary monthly meeting of the London Association of Foremen Engineers will be held at the City Terminus Hotel, on Saturday, October 2, when Mr. Nicholson will read a paper on a new expansive steam engine. The chair will be taken at 8 p. m. precisely, by Mr. Joseph Newton, Royal Mint, President.

A MEETING of great interest to admirers of horses will take place in France on October 4, 5, and 6. General Fleury, Grand Equerry to the Emperor, and who is charged with the direction of the Government breeding-studs, will proceed at that period to Le Pin, in Normandy, to preside over the commission charged with purchasing Anglo-Norman stallions required for the State establishments.

ACCORDING to an American paper a man who owes a bill in London can now pay it in four hours by simply going to Wall-street and purchasing a document known as a "cable transfer," a device born of the great Atlantic telegraph enterprise, whereby the equivalent of the money which he gives in New York will be immediately delivered to his creditor in London.

A NUMBER of submarine sweet water springs are known to exist along the coast of Istria and Dalmatia. As the coastal districts of these provinces suffer from want of a sufficient supply of water, and it is possible by means of the Norton pump to save much that is now lost, the Austrian Ministry of Agriculture has published a book on the means of finding and utilising submarine fresh water springs on the Austrian coasts.

THERE is one curious feature in the present short crop of cotton in Queensland that, whilst some planters have gathered from one bale to one bale and a half per acre, others have come off with practically nothing at all. A great deal of this difference proceeds from the various descriptions of soil in which the cotton has been planted, and it is strongly suspected that the rich scrub lands and strong black soil are not so well adapted for the plant as lands of a poorer description.

THE number of visitors to the South Kensington Museum during the week ending September 18, 1869, was—on Monday, Tuesday, and Saturday (free), from 10 a.m. to 10 p.m., 11,467; Meyrick and other galleries, 1,894; on Wednesday, Thursday, and Friday (admission 6d.), from 10 a.m. till 6 p.m., 1,723; Meyrick and other galleries, 128; total, 15,212. Average of corresponding week in former years, 12,543. Total from opening of Museum 8,808,067.

OLD Paris, in 1852, was lighted by 12,579 street lamps, of which 12,494 were gas, and 85 oil lamps. This part is now lighted by 21,061 lamps, of which 20,781 are gas, and 280 oil lamps, being an increase of 8,482 lights. The suburban zone, in 1850, was lighted by 2,484 gas and 434 oil lamps; there are now 11,539 gas and 1,252 oil lamps, being an increase of 9,880 lights. The total number of lamps used for the illumination of the city, including the suburban zone, is 33,859, of which 32,320 are lighted by gas, and 1,539 by oil.

ANOTHER case of living cochineal insects (presented by Messrs. Wetherell, Quintas, and Co., of Grand Canary and London) has just arrived at the Botanic Gardens, Regent's Park. The insects, as well as the cactus plants on which they are feeding, appear to be in good health, but it is doubtful whether the change of climate will agree with either. It has been found exceedingly difficult to keep in good health the insects imported last year from Madeira; a few, however, remained alive during the winter, and have this year produced young.

A VALUABLE discovery of bismuth ore has been made on a section belonging to Mr. Camac, near Balhannah, South Australia. Mr. Ey, whilst overlooking some workmen engaged in opening up the hillside in search of a copper lode, believed from surface indications to exist there, had his attention directed to the weight of the stuff dug up. A number of specimens were brought to town, and further examination has proved them to be bismuth ore of a very rich description, and only impregnated with copper to a very slight extent.

THE "New York Herald" understands there is a new and remarkable invention, an automatic system of self-telegraphing power, which will multiply eight or ten times the facilities of telegraphic communication over the present system. There is reason to believe this is one of the most astonishing inventions of the age, and destined to produce a great revolution in the commerce, financial affairs, intercourse, and social conditions of the world. We learn, also, that the United States Government will be asked to test this invention and to take the control of and use it for the public good.

THE latest advices with regard to the progress of the Suez Canal are to the effect that the Bitter Lakes had on the 5th inst. about 3.20 metres wanting to bring them up to the level of the Mediterranean. Hence as they wanted on August 15 5 metres to bring them up to that level, it appears they have risen 1·80 metres in 21 days, being at the rate of about 9 centimetres a day. It therefore now seems highly probable that the lakes may be filled before November 17. The completion, however, of the rest of the works in time for the proposed opening on that day is still considered in some degree uncertain.

THE inhabitants of Gibraltar were lately gladdened by the discovery of an unexpected source of water supply at the north front of the garrison. A specimen was carefully analysed by Dr. Power, of the 74th Highlanders, and the water was pronounced to be of a satisfactory character. Since that time specimens have been forwarded to several eminent chemists in this country, and the results of their analyses are corroborative of those obtained by Dr. Power. There is abundance of water from this new source, and the importance of the discovery is manifest when we consider the character of the Rock, and the requirements made upon it by shipping, garrison, and residents.

A SECOND bronze statue was successfully cast on the 6th inst., at Messrs. Holbrook and Co.'s works, Chelsea, of Marshall Wood's much-admired figure of the Queen. The casting of the first statue, which was sent to Montreal, was described in the MECHANICS' MAGAZINE for April 30 last. The work for the present casting was commenced on June 7, so the formation of the mould has occupied exactly three months. Very great care appears to have been taken in the moulding, for notwithstanding the rapidity with which the work has been executed we find the casting very sound and the outlines remarkably sharp. The statue, weighing upwards of two tons, was cast entire in one piece, although, according to the present system of statue founding, it is unusual to do so in figures of these dimensions.

THE Hatcham Ironworks, well known as the property of Mr. George England, have just been taken on a lease for fifty years by a company, consisting of Mr. Robert Fairlie, Mr. George England, jun., and Mr. John Simpson Frazer, late of the Great Western Railway. Mr. George England has retired from ill health. The works will be carried on with spirit and enterprise, we have no doubt, the assistance of so able an engineer as Mr. Frazer being a matter of no small importance. The principal business done will consist in the construction of the Fairlie double-bogie engine and light steam carriage, with which our readers must be familiar. The plant and machinery at the Hatcham Ironworks are very valuable and extensive, and the place possesses remarkable facilities for turning out good work.

Patents for Inventions.

ABRIDGED SPECIFICATIONS OF PATENTS.

THE Abridged Specifications of Patents given below are classified, according to the subject to which the respective inventions refer, in the following table. By the system of classification adopted, the numerical and chronological order of the specifications is preserved and combined with all the advantages of a division into classes. It should be understood that these abridgments are prepared exclusively for this Magazine from official copies supplied by the Government, and are, therefore, the property of the Proprietors of this Magazine. Other papers are hereby warned not to produce them without an acknowledgment:—

BOILERS AND FURNACES—586, 597, 603, 630, 633
BUILDINGS AND BUILDING MATERIALS—331, 585, 627, 633, 646, 651
CHEMISTRY AND PHOTOGRAPHY—291, 600, 612
CULTIVATION OF THE SOIL, including agricultural implements and machines—625
ELECTRICAL APPARATUS—288
FIBROUS FABRICS, including machinery for treating fibre pulp, paper, &c.—347, 590, 596, 608, 610, 613, 619, 638, 650
FOOD AND BEVERAGES, including the apparatus for preparing food for men and animals—470
FURNITURE AND APPAREL, including household utensils, time-keepers, jewellery, musical instruments, &c.—109, 268, 269, 290, 584, 588, 593, 601, 629, 631
GENERAL MACHINERY—583, 594, 602, 604, 605, 642, 644, 647, 648, 649
LIGHTING, HEATING, AND VENTILATING—647, 648, 649
METALS, including apparatus for their manufacture—28, 598, 616, 632
MISCELLANEOUS—222, 255, 582, 529, 607, 614, 615, 618, 620, 621, 626, 628, 637, 640, 641, 643, 653
ROADS AND VEHICLES, including railway plant and carriages, saddlery, and harness, &c.—286, 365, 580, 587, 589, 592, 606, 609, 634, 636, 639, 652
SHIPS AND BOATS, including their fittings—584, 595, 654
STEAM ENGINES—298, 312, 623
WARFARE—591, 611, 617, 624

28 E. FOX, Sheffield. *Iron and steel.* Dated January 5, 1869.

This consists in melting and refining, in an ordinary cupola or otherwise, any or all descriptions of cast and wrought-iron scrap or pig metal or certain quantities of each, and when melted, in running them into pigs, or they may be used in the molten state to be worked in the puddling furnace in such proportions as may be found desirable for the production of various descriptions of iron and steel.—Patent abandoned.

109 R. WATSON, Birmingham. *Stop work in chronographs.* Dated January 14, 1869.

Hitherto in order to stop and start the pieces several actions of a complicated nature have been required, but in this invention the starting is effected by providing a toothed wheel having contrate or upright teeth or pins, acted upon on one side by a spring click, which being pressed by the push-piece drives the toothed wheel one space. On the other side a spring detent acts on the upright teeth or pins of the wheel, and this detent carrying a small spring is allowed to descend on the balance by means of the revolution of the toothed wheel.—Patent abandoned.

222 J. M. MERRICK, Massachusetts. *Composition for ornaments.* Dated January 25, 1869.

This composition is termed diatite, and the ingredients are gum shellac or its equivalent and finely powdered silica, the latter being prepared in any proper manner well known to chemists or mineralogists, or existing in nature in the form of a diatomaceous deposit or infusorial earth.—Patent completed.

255 T. BROOM, Newgate-street. *Water hose.* (A communication.) Dated January 27, 1869.

The inventor employs a strong and tight metallic vessel enclosing a smaller vessel or tube, the latter extending nearly to the bottom of the main vessel. The tube opens at bottom into the main vessel, and is closed at the top by a screw cap, this cap being outside the top of the main vessel. The main and smaller vessels are united at the top. The tube has an aperture through it about one-fourth of its length from the top, and just above this aperture is a wire or open partition for supporting the combustible charge, whereby the gas is evolved. The main vessel may be of the proper size to hold any desired quantity of water, and is made preferably tight. The vessel is provided with a waste cock and an ejecting tube. The screw cap is inserted into the top of the tube and has an aperture through it, which is tightly closed by a screw plug.—Patent abandoned.

268 C. D. ABEL, Southampton-buildings. *Washing apparatus.* (A communication.) Dated January 28, 1869.

A row of beaters or stampers guided in a framing are arranged to act upon the surface of a long horizontal revolving cylinder partially immersed in a trough containing soap-water or other fluid, round which cylinder the textile fabric is caused to pass in a helical direction, being guided for this purpose by a number of stationary guiding bars arranged along the cylinder, and the fabric is furthermore held against the cylinder by one or more pressing rollers.—Patent abandoned.

269 C. A. L. HOELSCHER, Geneva. *Musical seat.* Dated January 28, 1869.

The inventor hinges the seat to the frame at the back front on either side, but he prefers to hinge it at the back; in the first case, he simply retains the musical works (already wound up) by a detent, and allowing a slight downward motion of the side of the seat opposite the hinge to take place as the weight of the body comes upon it. He employs this motion to release the detent, and thus allow the action of the mechanism to commence.—Patent abandoned.

286 A. MALLARD, Moorgate-street. *Horseshoes.* (A communication.) Dated January 29, 1869.

This consists in roughing the surface of the shoe next the ground by forming channels or grooves therein, in any suitable manner, thus producing ridges or ribs on the surface of the shoe, which enables the animal to obtain a firm hold of the ground at all times.—Patent abandoned.

288 T. E. LUNDY and T. HOOD, City-road. *Driving sewing machines by electro-magnetism.* Dated January 30, 1869.

The inventors fix an armature to an ordinary electro-magnet by means of a real magnet at the bottom (or in any other suitable position) of the electro-magnet, and by this means the poles of the upper magnet become permanently magnetised. When a current arrives it demagnetises the electro-magnet, and the armature at once rises, but so soon as the current has passed through the coils and completed its work in the apparatus, the power of the real magnet again acts upon the electro-magnet, and the armature is again fixed.—Patent abandoned.

290 P. J. WIELEINAUS, Lisle-street, Leicester-square. *Ovens.* Dated January 30, 1869.

This consists in constructing ovens for baking and other purposes with an inner and outer case, such inner case being so constructed as to leave a space or passage way all round the sides, top, and bottom (or nearly so) of such inner box or case, and between it and its receptacle or outer case, such space or passage way, when the oven is in use, being filled or nearly so with steam of a sufficient temperature for the purposes intended, and, by the means and application of steam in such manner, baking or cooking bread and other articles of food.—Patent abandoned.

291 W. WELDON, Park-villa, Highgate. *Regenerating manganese compounds.* Dated January 30, 1869.

This consists, first, in adding to a mixture of hydrated protoxide or other oxide or oxides of manganese with either water or a suitable saline solution, or to a mixture containing other substances in addition to hydrated oxide or oxides of manganese and either water or a saline solution, when either such mixture is to be treated with gaseous oxygen as contained in atmospheric air or otherwise, in order to the production of a highly oxidised compound of manganese, and either before the commencement of such treatment with oxygen, or at some stage during the progress thereof, any salt containing oxygen and capable of imparting oxygen to the oxide or oxides of manganese contained in the mixture to which it is added, and of then absorbing oxygen to replace that with which it has thus parted from the gaseous oxygenating agent with which such mixture may be afterwards or simultaneously treated, in such wise that a comparatively small quantity of such salt may carry oxygen to a comparatively large quantity of oxide of manganese.—Patent abandoned.

298 R. WOOD, Halifax. *Steam engines.* Dated January 30, 1869.

This consists in the application of a separate small steam cylinder and piston with an ordinary slide valve. The piston rod thereof is connected with another rod in communication with and giving motion to the spindle of the cut-off valve. The valve rod is provided with two collars or shoulders, between which are two cams mounted upon a hollow spindle, within which works a slidable rod connected to the governor by a bell crank lever and connecting rod.—Patent abandoned.

312 A. BARCLAY, Kilmarnock. *Ejector condensers.* Dated February 2, 1869.

This consists in leading a steam pipe supplied with steam from a boiler down through the centre of the nozzles of the ejectors or condensers or ejector condensers, under which various names these instruments are known. By means of this pipe a small supply of steam can be carried through the instrument at such times as may be required to ensure its operation.—Patent abandoned.

331 F. VANDERAEY, Uccle, Belgium. *Brick-making machinery.* (A communication.) Dated February 3, 1869.

This consists of a pug mill of the ordinary construction mounted above a series of moulds, which are placed in a circular or rectangular framing. The clay or other material is forced down to the lower part of the pug mill, where it enters moulds carried upon a circular table, which has a rotary motion communicated to it in any suitable manner. Beneath the table a wheel or drum is placed, upon which the bottoms of the moulds are brought to bear in their rotation. This wheel causes the moulds to rise so as to bring the upper surface against the under side of a fixed table or plank. In this operation the clay becomes compressed within the mould. The moulds with the materials within them then pass on towards a second wheel or drum, by which the bottom of the mould is lifted so as to cause the moulded article to project beyond the top of its mould. It can then be removed to a drying stack, or if the clay is sufficiently free from moisture it can be stacked or otherwise treated for burning.—Patent completed.

347 R. W. KNOWLES, Tong, Bolton. *Finishing muslins.* Dated February 4, 1869.

This consists in imparting to the endless chains or belts which carry the pins for holding the selvages of the muslin or other fabric a continuous progressive motion, but alternately fast and slow, being quick at one side whilst it is slow on the other, and *vice versa*, which is effected by the following means:—Instead of driving the pulleys round which the chains or belts pass by means of gearing which is alternately thrown into and out of gear, which is liable to get out of order, and is expensive and objectionable on various other grounds, the inventor drives the pulleys by means of a pair of elliptical spur wheels at or near each end of a shaft, the wheels being so placed that their longer axes are at right angles to each other.—Patent abandoned.

365 D. D. KYLE, Victoria-street, S.W. *Railway signalling.* Dated February 5, 1869.

Tubes are attached to the engine and carriages of a train so as to form along the train or any portion thereof one or more continuous tube or tubes when connected together. Stopcocks or other apparatus are arranged in connection with these tubes, to be acted on by the passengers, guards, or drivers, or by agency mechanically arranged in or external to the train, so as to destroy the continuity of the bore or channel of the tubes. Exhausting or pumping apparatus on the engine, guards' van, or other part of the train, wrought by power obtained from the engine or motion of the carriages, or by independent motion, is placed in connection with these tubes.—Patent abandoned.

470 V. A. HONDAILLE, Paris. *Metallic bungs.* Dated February 16, 1869.

The bung consists of two parts, that is to say, the body, which is screw cut at its shank, and is fixed into the bung-hole after being previously dipped in resin or other glutinous matter; and, second, the plug, whose shank also terminates in a screw for fitting into the interior of the

body, which is furnished with screw threads for the purpose.—Patent completed.

580 W. ANYON, Manchester. *Velocipedes.* Dated February 25, 1869.

The wheels, instead of being placed one behind the other, as in the vehicle known as the "French velocipede," are placed parallel or face to face on the same axle, and at any suitable distance apart, so as to suit the nature of the machine or the requirements of the operator. The shaft is provided with two cranks throwing in opposite directions. Upon each end of this shaft is a wheel, one or both of the wheels being fixed, and all the rest of the apparatus being suspended from or working loose upon the shaft in suitable bearings and below the centre of motion. The seat is slung from journals or bearings, through which the shaft passes, oil cups are provided for lubricating the shaft, a handle is fastened on each side of the seat rising from the bearings, and furnished with cross handle passing through the head.—Patent abandoned.

581 H. LOEWENBERG, Berlin. *Hat compound.* Dated February 25, 1869.

The inventor takes any suitable hat, bonnet, or other article of wearing apparel, and casts or presses thereon gum, or any other resinous or gelatinous substance, or sulphur or other mineral product, after which the hat or other article is removed and an exact fac-simile or mould thereof obtained. He then covers the inner or outer surface of the mould thus obtained with a layer of glue, or other gelatinous substance, or such substance in combination with glycerine or oily or fatty matters, either with or without any desired colouring matter, and when cold the hat shape thus formed is taken from the original mould, by which means the exact fac-simile of straw plait or any other pattern or design may be accurately impressed thereon.—Patent abandoned.

582 B. P. WALKER, Wolverhampton. *Abrasion shaping machinery.* Dated February 25, 1869.

This consists partly in the adaptation of the copying principle employed in the machines in use for the shaping of the wood stocks of guns, lasts for shoes, and such like articles, to the production of surfaces other than flat in articles of metal, and partly in special machinery and apparatus for grinding and polishing the edges and surfaces of the metal heels of boots and shoes, the edges of iron washers for machinery, and similar articles.—Patent completed.

583 W. TURNER, Dublin, and J. W. GIBSON, Dundalk. *Friction rollers.* Dated February 25, 1869.

This consists in the employment of an endless chain of rollers, in cast or wrought iron or other hard substance, passing round an iron or other block or bracket of an elliptical or oblong form having the upper surface perfectly straight for a distance equal to the length of an arm or link (each end of which serves as an axis to a roller), so that in any position of the rollers one, at least, will always be on the level or straight surface of the block.—Patent abandoned.

584 J. MOODY, York. *Mooring vessels.* Dated February 25, 1869.

In order, when mooring, to take the weight of a cable from the vessel or floating body, the inventor provides a cable made of iron or any other material divided in o short lengths of from, for instance, 30 to 40 or any number of fathoms, according to the nature of the cable used, or the form of the vessel or body, and the waters in which such mooring is to take place.—Patent abandoned.

585 W. PARKINSON, Gloucester Grove, Brompton. *Wood cutting.* Dated February 25, 1869.

This consists in combining in one machine a circular saw, a band saw, a machine for cutting mouldings or for planing, grooving, tonguing, edging, and thicknessing boards at one operation, and for cutting single or double tenons, and also scribing them at the same operation, and also for cutting curved or irregular mouldings.—Patent completed.

586 W. E. NEWTON, Chancery-lane. *Oxidizing furnaces.* (A communication.) Dated February 25, 1869.

This consists in arranging above the smelting point of a blast furnace pipes and tuyeres for the admission of water, steam, and air (either separately or combined) into the hot stock during the smelting operation, whereby sulphur or other impurities contained in the ore may be expelled and a better quantity of metal thereby obtained than heretofore.—Patent completed.

587 E. D. BARKER, Weston-super-Mare. *Railway brakes.* Dated February 25, 1869.

This consists, first, in transmitting a sufficient force to act on the brake blocks to skid or stop the wheels of an entire train in the shortest possible time so as to avoid collision. Second, in the power of adjusting the force with which the brake blocks are applied according to the state of the weather so as at all times in ordinary stoppages to be able to avoid skidding the wheels. Third, in having an equal pressure on all the brake blocks, and the pressure exerted against the brake blocks unaffected by unequal wear of the wood blocks. Fourth, in doing away with all the strains on the axles, axle guides, and framing incidental to the ordinary methods of applying the brake blocks.—Patent completed.

588 L. ENGEL, Mumford-court, E.C. *Parasols, umbrellas, &c.* Dated February 25, 1869.

The inventor connects together the two portions or lengths of the stock of a parasol, or umbrella, or sunshade by means of two tubes which are connected together, end to end, by a hinge-joint, and are at their opposite ends fixed the one on to the end of one length of the stick and the other on to the end of the other length of the stick. One of the tubes also contains a circular bolt capable of being slid out endwise from the tube so that its end may project therefrom. Through this tube is a slot through which a pin is passed into the bolt, and by this pin the bolt can be slid to and fro like the bolt of an ordinary door bolt.—Patent abandoned.

589 F. BRADY, St. John's-terrace, Regent's-park. *Switch apparatus.* Dated February 25, 1869.

The inventor applies alongside of one of the rails just in front of the points of the switches a bar of iron about seventeen feet long, two inches wide, and half-inch thick. This bar is secured to brackets at intervals of about four feet. These brackets are keyed on and turn with a shaft placed on standards or bearings parallel to the rail along side of which the bar is to be. The shaft is turned by the action of the switches, so that when the switches are either fully opened or fully closed the bar shall be out of the way of the flanges of the wheels. The bar is to be long enough to always have one wheel of a passing train over or at the side of it. The curved bar may be cut into sections in its length so as to avoid chairs or fish plates, or cheek chairs securing the rail with bolts counter sunk into the rib of the rail may be used where the curved bar is applied.—Patent completed.

590 W. R. HARRIS, Paris. *Weavers' harness.* Dated February 25, 1869.

This relates to healds made with a metallic eye attached to two threads or inserted in the strands of a single thread, and consists, first, in attaching the eyes at any regular distances within continuous threads or thread, and, second, in weaving such threads or yarns thus prepared in convenient lengths for mounting in the loom.—Patent completed.

591 W. T. ELEY, Gray's Inn-road. *Cartridge cases.* Dated February 26, 1869.

This relates to improvements in the construction of cartridge cases for breechloading fire-arms in which the charge is ignited by means of a pin projecting laterally from the cartridge. This pin is so arranged as to enter a metallic recess or cap chamber secured in the paper base or packing of the cartridge case. In this metallic recess the detonating mixture is placed in a cap or otherwise, so that upon the pin being struck the detonating substance is exploded and the charge ignited. This cartridge is well-known as "Lefaucheaux" or "pin-fire" cartridge. Now, according to this invention, the inventor arranges a metallic cup in front of the paper base or racking of cartridge cases of the description above referred to, such metallic cup having an aperture of suitable form for the insertion of the metallic cap chamber or recess. With the metallic cap he combines an annular coil of metal so formed as to extend a suitable distance along the interior of the cartridge case. The end of the annular metallic coil is partly closed and fits within the metallic cup. There is an aperture for the insertion of the metallic cap chamber or recess, formed in the end of the metallic coil similar to the apertures formed in the metallic cap for the same purpose. After the paper base or packing has been placed within the paper cartridge case provided, an external metallic cap as hitherto practised, the metallic cap and coil with the metallic cap chamber are introduced and pressed into the cartridge case. By the application of pressure the parts are consolidated and the metallic cap and coil securely held down by the flanges of the metallic cap-chamber. When applying pressure to the combined cartridge case the metallic coil is enlarged so as to fit the interior of the case at that part where the metallic coil extends beyond the paper lining of the cartridge case.—Patent completed.

592 H. J. LEDGER, Manchester. *Railway signals.* Dated February 26, 1869.

This consists in providing a thoroughfare of ample dimensions through the whole length of the carriages, and from one carriage to another if necessary, by forming a doorway and fitting a door in each division or partition which now separates carriages into compartments and if necessary in the ends of the carriages. These thoroughfares and doors by preference are situated above the seats, and the doors are made to slide up and down in grooves behind the seats, so that when closed such doors give all the privacy to each compartment which at present exists. When closed such doors are fastened by means of a self-acting hook, which is acted upon by a lever or series of levers connected to a rod running along the whole length of the roof of the carriage. In each compartment a chain is suspended which is connected to an arm branching from the longitudinal rod, turns partially in its bearings, and thus the hooks are caused to release all the doors in such carriage so as to open up a communication through the sliding doorways, between all the compartments; one of such doors in falling comes in contact with the longer arms of two levers, thereby depressing them and causing their shorter arms to be raised up, these latter, having peculiar clutches connected to chains attached to them, in rising push out a semaphore signal, and at the same instant pull the ordinary rope which passes from one end of the train to the other, and thus actuate the hammer of a gong situated either in the guard's van or on the engine, or both, or if connected with a steam whistle cause it to sound an alarm.—Patent completed.

593 H. HARBURG, Hatton Garden. *Musical boxes.* Dated February 26, 1869.

The inventor provides, in such a position as to be clearly within view, a plate, dial, or appliance on which are marked numbers or words, or both, indicating the various tunes played by the musical box. These being disposed in the proper order, the inventor fits or mounts a pointer or indicating contrivance close to this plate, dial, or appliance, and works the same by the working parts of the musical box, so that when the barrel moves or is shifted in order that a new tune may be played, the pointer will be moved accordingly, and will point on the plate or dial to the number, name, or indication of the particular tune corresponding with the particular position of the barrel. If the barrel be set at "repeat," that is to say if it repeats its tune, the pointer remains in the same position.—Patent abandoned.

594 T. MOORE, Stockton-on-Tees. *Applying power.* Dated February 26, 1869.

This refers to a patent dated 3rd April, 1867 (No. 990). To a frame which supports the whole apparatus the inventor forges or casts bosses on which two lifting wheels are free to resolve loosely. A spindle passes through the bosses, to the outer end of which he keys a hand chain wheel; between the lifting wheels he places a frame also keyed or forged to the spindle, and this frame carries pinions at its outer end, by preference four, but one or more may be used. The pinions are free to revolve on their own axes, and at the same time to gear into teeth formed on the lifting wheels.—Patent completed.

595 W. R. LAKE, Southampton-buildings. *Ships for liquid cargoes.* (A communication.) Dated February 26, 1869.

This consists in making the tanks closed on all sides and separate from the sides of the ship, but placed centrally therein, and of such size and shape that when entirely filled with the liquid cargo the centre of gravity of the same will bear such a relation to the centre of gravity of the ship and centre of displacement that the cargo will properly trim the ship.—Patent completed.

596 J. CHEETHAM, Chadderton. *Winding yarns.* Dated February 26, 1869.

Instead of winding the yarns or spools which need to be conveyed as well as the yarn, the inventor makes the bobbins in two or more parts, so that when the material has been wound upon them they may be removed and the yarn transmitted without them. The form in which he prefers to wind the yarn constitutes, when finished, a cylinder solid in every respect except the part which was filled by the bobbin, being so frequently crossed in the building that it will retain its bulk and form as well without the spool or bobbin as with it.—Patent completed.

597 J. A. F. SUTER, Hereford, and T. C. HINDE, Fownhope. *Furnaces.* Dated February 26, 1869.

The inventors construct the furnace of two or more principal parts, namely, of a gas-generating chamber, a combustion chamber, and a superheating chamber. In the first, or gas chamber, the coil peat or other solid fuel is converted into gaseous fuel by being ignited and supplied with a sufficient quantity of air to convert the carbon of the fuel into carbonic oxide. The second chamber of the furnace consists of a reverberatory or other chamber into which gaseous fuel produced in the first chamber, mixed with the requisite quantity of air for combustion, is burned. In the third or supplementary chamber, the gaseous fuel may be heated prior to being burned in the combustion chamber.—Patent completed.

598 G. J. HINDE, Wolverhampton. *Coating with copper.* Dated February 26, 1869.

The inventor cleans the sheets or articles to be coated by any of the well-known pickling or other processes ordinarily employed for that purpose, and he plunges the sheets or articles into a bath of melted zinc containing copper in alloy with zinc, the quantity being so large compared with that of the copper as not to materially affect the colour of the zinc. From 5 to 6 parts by weight of zinc to 1 part by weight of copper is found to answer well in practice. After a short immersion of the iron or steel sheets or articles in the bath, they are withdrawn and exposed to heat in a muffle or heating chamber sufficiently hot to volatilise the zinc, and the sheets or articles are allowed to remain in the muffle or heating chamber until so much of the zinc has been volatilised as to leave brass upon the sheets or articles, or when a coating of copper is required the sheets or articles are allowed to remain in the muffle or heating chamber until the whole, or nearly the whole, of the zinc has been volatilised. In order to prevent the sheets or articles from adhering together or receiving any injury to their coating, the inventor prefers, before putting them in the muffle or heating chamber, to coat them with a mixture of finely ground calcined flint and water. This coating, when dry, protects the surface of the metal, and does not prevent the volatilisation of the zinc. After the sheets or articles are removed from the muffle or heating chamber, the coating of powdered flint is removed. The articles are finished by burnishing or otherwise, and it is preferred to pass the sheets that have been coated according to this invention through a pair of plain rolls in order to give smoothness to the coating.—Patent completed.

599 J. T. H. RICHARDSON, Tutbury. *Glass cutting.* Dated February 26, 1869.

The apparatus made use of consists, principally, of an upright or other standard screwed or otherwise fixed to another standard sliding vertically, and capable of being fixed at any required position in a socket secured to the bottom of the plate, so that the cutter may be inserted and adjusted in the glass to the required height. The standard is lowered after cutting to allow the removal of the glass. There is a bottom plate provided underneath with castors, so that it is capable of being turned round and of running in any direction. At any convenient height of the standard two arms project, and between these arms a curved lever is fixed at or about its centre by screws or otherwise. The bottom of this lever is pressed outwards by means of a spring or other suitable contrivance which is fixed to the standard. At the back of the standard a thumb screw is placed which allows of the spring being pressed or relieved, thus causing the diamond or hard cutting material at the top of the lever to press against the glass with more or less force. At the top of the standard two arms project. These arms have a mouth or cavity formed in them, and are each fitted with a small disc or circular piece of steel, which discs are allowed to turn on a pivot securing them between the jaws of the arms. The top of the curved spring lever is formed of a head through which a rectangular or other conveniently shaped orifice is made. In this orifice the piece of steel which contains the diamond or hard cutting material is placed.—Patent completed.

600 J. TOWNSEND, Glasgow. *Oil refining.* Dated February 26, 1869.

Steam generated in any convenient boiler is passed through piping immersed in a bath of melted metal or alloy, or of a salt or salts in solution, or fused, which superheats it and keeps it at a uniform temperature, and it is then admitted into a retort or still containing the materials from which the oils or other products are to be extracted. The superheated steam enters the upper end of the retort, and is maintained therein at a pressure of at least ½lb. per square inch above that of the atmosphere.—Patent completed.

601 E. FALCK, Cheapside. *Distributing scent.* (A communication.) Dated February 26, 1869.

The inventor proposes to construct a vessel in the shape of a vase or urn provided with a cover which can be hermetically closed. The top of the cover is provided with an opening by which the aromatic or disinfecting liquid or perfume can be poured in, the aperture being closed by a close fitting stopper. Around the vessel, just below the cover, is a series of projecting tubes. Inside the vessel a series of other tubes are fitted, these spring from near the centre of the bottom of the vessel, and lead upwards and into the necks of the projecting tubes. A tube, larger in diameter than the two series of tubes, rises up through the liquid to near the top of the vessel, where it is bent over so as to direct the current of air downwards upon the surface of the liquid. The lower end of this tube passes through the bottom of the vessel, where it is connected by a flexible pipe with a compressible ball or other shaped receiver provided with a mouthpiece or not.—Patent abandoned.

602 J. REAP and W. H. MICHELMORE, Borough-road, Southwark. *Spring hinges.* Dated February 26, 1869.

The pin or vertical axis of the hinge is mounted in bearings so that it can turn freely through rather more

than a quarter revolution either way. The upper part of this pin is squared so as to receive a lever or shoe which is affixed to the lower angle of the door, which thus turns on and with this pin as an axis. On the pin are mounted two rollers so as to turn on vertical discs which are at some distance from the axis of the pin itself. Two curved jaws are mounted on vertical axes, one on each side of the hinge pin, and are acted on by a spring so as to make them close tightly together towards the hinge pin, and these jaws are geared together so that when either one of them is caused to move from the hinge pin, the other also moves from the hinge pin. The rollers already described bear on the inner surfaces of these jaws one upon each, and each of these faces is made of such curvature that when by moving the door the hinge pin with its roller is turned the roller running on either face causes the jaws to expand against the force of the spring, and, consequently, when the door is left free the force of the spring, tending to make the jaws close together, causes the rollers to be passed towards the middle position, and so closes the door.—Patent completed.

603 C. MARKHAM, Brimington, Derby. *Boilers*. Dated February 26, 1869.

The inventor forms the boiler of a number of sets of tubes each composed of two horizontal tubes at a distance apart from one another, and connected at intervals by vertical tubes, which are cast in one piece with them. Several such sets of cast tubes are set up side by side with the ends of all the horizontal pipes passing through two parallel brick walls which form the side walls of the boiler furnace. One end of each of the horizontal tubes is by preference closed by a cap or cover, whilst the opposite ends of all the lower horizontal tubes are connected to a pipe to which the feed water is admitted, and the opposite ends of all the upper horizontal tubes are similarly connected to a pipe which forms a steam chamber. The several sets of tubes are thus each connected to a feed water pipe and to a steam chamber, and all the joints by which they are connected to these pipes are exterior of the boiler furnace, so that they are not affected by the heat of the fire.—Patent abandoned.

604 W. A. HERRING, Chertsey. *Pumps*. Dated February 26, 1869.

The inventor employs a cylinder or pump barrel, open at both ends and supported at its centre by a ring standing out from its exterior and passing to the sides of a casing by which the pump barrel is surrounded. The casing is thus divided into two compartments, one open to one end of the cylinder while the other is open to its opposite end. The piston rod passes out through a stuffing box in one end of the casing, and has a to and fro motion given to it in any suitable manner. From opposite sides of each compartment of the casing passes a pipe or passage, the passages from one side leading to an inlet valve box, whilst the passage from the other leads to an outlet valve box.—Patent completed.

605 C. WILLIAMS, Plumstead. *Motive power*. Dated February 26, 1869.

The exhaust pipe of any engine worked by steam, air, or other gaseous fluid under pressure is passed into the reservoir or generator containing such gaseous fluid, and the exhaust steam or gaseous fluid is drawn or forced into the reservoir or generator by preference by means of a current of the steam or gaseous fluid circulating through pipes or boxes contained within the reservoir or generator, stopping its back-flow by valves, or otherwise, and ensuring its passage into the reservoir or generator by means of a small amount of power expended, if necessary. —Patent abandoned.

606 J. ADAMS, Arlington-street, Sadler's Wells. *Railway communication*. Dated February 27, 1869.

The inventor avails himself of the air generated by the progress of the train to produce an audible signal, by ringing an alarum or bell in the guard's van. To carry this into effect he places upon the roof of each carriage a length of chain hooked together between each carriage, forming a continuous chain from end to end of the train and connected to an alarm bell in the guard's van and also upon the tender of the engine. He then mounts upon the roof of each carriage a box or channel, 18in. long, containing a fan wheel or screw blades with a flange, drum, or pulley outside the box or channel, and connected to the fanwheel or screw blades inside and fastened to this pulley is a length of chain, which is hooked into the continuous chain.—Patent abandoned.

607 W. THOMAS and W. DAVIS, Aberdare. *Mine-winding machine*. Dated February 27, 1869.

This consists in placing a grooved drum and two pulleys in a vertical position upon frames erected directly over the opening to the mine or pit, and, instead of a pair of ropes, a single rope is used, which is passed over the drum or pulleys in two or more coils. To each end of this rope a cage is attached, and by this means one entire length of winding rope is dispensed with. Steam or other motive power is proposed to be applied for lifting and other purposes, directly to the spindle or shafts of the upper drum or pulley, by fixing thereto the crank of an oscillating or other engine or engines, placed immediately adjoining to or at a distance from the drum or pulley, or this may be effected by means of a single engine driving a spur wheel in gear with toothed wheels attached to the two vertical drums or pulleys.—Patent completed.

608 J. R. CROSKEY, King William-street, E.C. *Looms*. Dated February 27, 1869.

This consists, first, in the construction of an apparatus for the purpose of propelling the air after the apparatus shall have been actuated by suitable mechanical contrivances. Second, in a novel means employed for arresting the speed of the shuttle and preventing its recoil after it shall have been driven across the race. Third, in the novel combination of motions and in mechanical arrangements connected therewith, for the purpose of actuating an air propelling apparatus.—Patent abandoned.

609 R. PYNE, Wellington-street, Strand. *Railway buffers*. Dated February 27, 1869.

This consists in a buffer carriage to be attached in the front or rear of a railway engine or other carriage, so that in case of collisions in front or rear the effects of the concussion may be received by the buffer carriage, and the dangerous results may be thus more or less obviated. The buffer carriage mounted upon axles and wheels is made of two or more compartments, so arranged as to slide within each other after the manner of a telescope.—Patent abandoned.

610 J. H. JOHNSON, Lincoln's Inn-fields. *Raw silk measuring*. (A communication.) Dated February 27, 1869.

This consists, first, in measuring the exact length of silk in each skein by self-acting mechanism. Second, in obtaining by self-acting mechanism hanks or skeins of a given length. Third, in ascertaining exactly the number of skeins in a hank.—Patent completed.

611 C. MAW, Aldersgate-street. *Cartridges and torpedoes*. Dated February 27, 1869.

In manufacturing cartridges for firearms and ordnance according to this invention in place of employing gunpowder or gun cotton as the explosive material, the inventor uses gaseous explosive compounds. For this purpose he forms the case of his cartridge either of metal, paper rendered impervious to the gaseous compounds, or any other suitable substance, and to explode the cartridge, he employs a cap or percussion arrangement fitted to it similar to those now in use with many kinds of cartridges used for breech-loading weapons.—Patent abandoned.

612 T. S. BLAIR, Pittsburg, Pennsylvania. *Mixing oxide and iron*. Dated February 27, 1869.

This relates to a patent dated November 23, 1868, No. 3565. The inventor now causes both the fluid cast-iron and the granulated oxide (which can be made to flow in a manner similar to a fluid, and with which may be previously mixed any substances acting as detergents or alloys) to be received each into the upper end of a separate inclined spout, trough, or shoot, the two troughs being set opposite each other, so that their lower ends approach each other, sufficiently to cause the contents of the two to flow or dash into each other soon after leaving the troughs, but not until each has so left or cleared its trough. If the two currents meet to any considerable extent upon either trough, a dam would form from the almost instantaneous "freezing" which takes place when the contact is effected. The inventor causes the oxide to flow in a flat stream by placing a gate at the upper end of its spout, nearly as wide as the spout, and regulated by sliding the gate up and down, so as to liberate a greater or less quantity at will. He causes the molten cast iron to flow in a flat stream of nearly equal thickness by placing a dam or dams across the spout, whereby to sperad it out upon one level.—Patent completed.

613 E. CHAPMAN, Egremont. *Carding engines*. Dated February 27, 1869.

This consists in the application to carding engines of a rotating roller or rollers covered with pins or teeth working into the outer interval between the rollers of the carding engine, commonly called the workers, and the clearing rollers or strippers. These additional rollers, which may be called combers, are placed near the part where the strippers take the fibres from the workers. The fibres taken by the cylinder from the feed rollers are carried forward, and in the usual manner left upon the teeth of the various workers, which are in their turn cleared by the more rapidly revolving strippers.—Patent abandoned.

614 T. ATKINSON, Bradford. *Fire lighting*. Dated February 27, 1869.

This consists in the use of a box or chamber, by preference constructed of cast iron, but may be of other material, in which are a series of perforations or small apertures, and a larger aperture into which is inserted a pipe of any convenient length. This box is introduced into the fireplace and coal or other fuel placed upon it, an indiarubber or other flexible pipe is then applied to connect it with a gasburner in any convenient position. Then by turning on the gas it will issue through the perforations, and on being ignited, will light or ignite the fuel.—Patent abandoned.

615 R. S. NORRIS, Liverpool. *Getting coal*. Dated February 27, 1869.

At the front of the seam of coal the inventor places a bed or frame of metal carrying a sliding block, which is moved forwards and backwards along the bed by means of a screw and nut worked by hand or power. The sliding frame carries one or more cutters, and also a screw having a nut to which the cutter or cutters are connected, and when two cutters, one above the other, are used, the nut is provided with slots through which the back ends of the cutters are passed, there being small eccentrics for alternately placing the cutting edge of one cutter slightly in advance of the other.—Patent completed.

616 G. J. SNELUS, Dowlais, Glamorgan. *Reducing iron ores*. Dated February 27, 1869.

This consists in reducing iron ores by first crushing or otherwise bringing them into a state of powder, and then feeding them continuously into a vertical chamber containing a series of horizontal bearers, as in the calcining furnace known as "Gherstenofer's," such chamber being kept at a red heat by any convenient means and filled with reducing gases at a pressure slightly above that of the atmosphere.—Patent completed.

617 L. G. LYSONS, Aberdeen. *Signals for artillery practice*. Dated February 27, 1869.

Planted in the ground a little distance in the front of the butt out of the line of fire, is a pole with a socket in which a lighter pole is swung, kept erect by means of weights, but easily pulled down into a horizontal position by a cord attached to the top running along the range to the firing party; on this lighter pole a red square is stretched either of bunting or painted tin or iron perforated with holes in case of wind.—Patent completed.

618 P. S. REGNAULD, Paris. *Fixing canister lids*. Dated March 1, 1869.

This consists in giving a suitable shape to the rims of the parts of canister lids for causing them suitably to overlap and allow of their being hermetically fixed together by mere pressure and the previous interposing all round between the overlapping parts of a strip of calico, linen, paper, or other suitable thin material in combination or not with any suitable cement.—Patent completed.

619 J. LADLEY, Leeds. *Spinning and twisting machine*. Dated March 1, 1869.

This consists, first, in the application to such machinery of pairs of drawing or delivery rollers, constructed in two or more parts longitudinally, such parts being operated so as to move a slide endwise in opposite directions, as described in the specification of a patent dated April 4, 1867 (No. 1009). Second, the improvements relate to that class of frames which stop running while the doffing of the bobbin is effected, and the improvements consist in the application of means to avoid having the ends or threads to attach to each empty bobbin separately. For this purpose the inventor introduces a boss or collar under the bobbin or betwixt it and the wharle recessed or cupped to receive the bobbin, and he arranges so that the lifter rail drops below the bottom of the bobbin at the time of doffing, so that the yarn will wind upon the boss and remain there unbroken, while the frame is standing ready to be wound upon the new empty bobbin when the lifter rail is raised into suitable position for the purpose.—Patent completed.

620 R. J. GOODBODY, Tullamore, King's County and R. E. DONOVAN, Upper Rathmines, Dublin. *Tobacco apparatus*. Dated March 1, 1869.

The inventors construct metal tubes or receptacles of a cylindrical, square, or polygonal transverse section either open at both ends or closed at one end, one or more of which tubes they place inside or pass through a closed metal casing or jacket, into or through which steam, water, or other fluid, either hot or cold as the case may be, is made to flow into these tubes; they place the roll, twists, cakes, or layers of tobacco with a metal plate intervening between each roll or layer, and press them down in a tube by a screw or other suitable contrivance, while or before or after heating or cooling until the requisite degree of compression is attained, and the top plate is then screwed down so as to maintain the tobacco in the compressed state while subject to the action of heat from the steam jacket or while cooling. The requisite heat is imparted directly to the circumferences of the rolls or layers, and by conduction through the intervening metal plates to both end surfaces thereof.—Patent completed.

621 J. RUST, Lambeth. *Ornamental composition*. Dated March 1, 1869.

This composition consists of glass, enamel in powder, and caustic lime or cements, for instance, Keene's or Portland cement may be substituted for caustic lime mixed together.—Patent completed.

622 The abstract of this specification will appear in our next number.

623 W. SIMPSON and A. GARDNER, Ilford. *Steam engines*. Dated March 1, 1869.

This engine consists of two crossheads, embracing the eccentric plates at opposite points of its periphery throughout its rotation, and there are tie and guide rods for securing the crossheads at a parallel distance from each other, so as to allow the plate to rotate freely between them without play or shake. To the driving shaft of the engine the plate is keyed or otherwise fixed. The piston rod is keyed to a boss on the crosshead. The plate is formed with a boss, in which is turned a groove, which fits in between the rods to preserve the vertical or direct movement of the piston rod.—Patent completed.

624 A. H. BRANDON, 13, Rue Gaillon, Paris. *Metallic cartridge*. (A communication.) Dated March 1, 1868.

This relates to that class of metallic cartridges where the head and the shell are made of one piece of metal. To form cartridges the inventor takes a blank round piece of metal of the required thickness, and forms it under a press with suitable dies into a concave cup. He successively passes this cup through decreasing sizes of dies, so that its sides are gradually drawn out and form the shell of the cartridge, the head during this time retaining its original thickness. He then compresses the head under a press, by which he forms the rim of the recess or cavity in which the priming cap is placed, and, if requisite, pierces the hole by which the fire communicates with the charge. —Patent abandoned.

625 W. R. LAKE, Southampton-buildings. *Lawn mowing machine*. (A communication.) Dated March 1, 1869.

The frame of the machine is formed of two side plates of cast iron secured together by a bolt at the back of the large roller and by the cutter. The roller acts upon the ground and gives motion to several wheels and the revolving cutter. A train of geared wheels is used for multiplying the velocity and for conveying motion from the roller to the revolving cutter. The large wheel is upon the same axis as the roller, and is attached to the roller by a ratchet and pawl, so that it will be driven by the roller when the machine is moved forward, but will be loose when the machine is drawn backward. This arrangement prevents the turning of the cutter in moving the machine from place to place. The wheel may, however, be firmly attached to the roller. Another wheel gears into a pinion on the axis of the revolving cutter and drives it rapidly in the direction of the arrow.—Patent completed.

626 D. DAVIES, Crumlin, Newport. *Getting coal*. Dated March 1, 1869.

The inventor employs as the cutting tool a spindle carrying a number of circular saws set at a slight angle upon it, or other cutters set around the spindle might be employed in place thereof. This spindle is carried in suitable bearings by a truck or carriage in such manner that it can be set at any desired angle from the horizontal, so that when rotated the portion of the spindle which projects beyond the bearings and which carries the saws or tools, may be caused to cut grooves into the coal or mineral at any desired inclination. The spindle is also so mounted that it can be caused to sweep in a circle around the truck or carriage, so that when thus caused to sweep round it may be caused to cut a groove in the form of a segment of a circle into the coal or mineral. For this purpose it is preferred to form the framing of the truck or carriage which carries the spindle and the apparatus employed for giving motion thereto in three parts. Each of the end portions of the framing is supported by a pair of wheels, one placed on either side of it. These wheels are to be run on rail or tramways laid in front of the face of the coal or mineral that is being worked. The central portion of the framing which carries the cutting spindle and the apparatus for giving motion thereto is connected to each of the end portions by axes upon which it can be turned. The spindle carrying the cutters can thus be brought to any desired angle from the horizontal, and when the machine is at work the three parts of the frame are bolted up together so as to form one rigid frame. The bearings carrying the spindle are carried by a cylinder supported externally in suitable bearings in the central frame, so that the cylinder may be revolved on its axis by means of a worm-wheel gearing into teeth formed around it. Within the cylinder and carried by it is the cylinder or cylinders of an engine for giving a rotary motion to the spindle. This engine may be worked by compressed air or otherwise.—Patent completed.

627 J. CLIFF, Runcorn. *Substitute for fire-brick*. Dated March 1, 1869

Instead of using fire-bricks, lumps, stones, tiles, or other forms of materials or compounds in construction, burnt or unburnt, the inventor uses powdered or reduced ganister, stone, quartz, sand, mica, sandstone, or other siliceous

material, plumbago, lime, baryta, steatite, and magnesia, alone or separately, or in varied proportions with fire-clays, or with each other, or with siliceous or other solutions, mixed or not with hair, fibre, sawdust, shavings, or pulverized coke, or with other analogous materials.—Patent completed.

628 J. HADLEY, Upper Thames-street. *Decorticating apparatus.* Dated March 1, 1869.

The decorticator consists of a vertical external cylinder, within which is mounted a vertical spindle carrying friction surfaces, which work within segmental friction surfaces carried by the cylindrical case. To these rotating friction surfaces it is preferred to give the form of rings, which are separated from each other by annular plates attached to the cylindrical case of the machine, and in these plates openings fitted with sliding doors are made to discharge the grain from the upper to the lower compartments formed by the plates.—Patent completed.

629 A. H. HONEGGER, Manchester. *Portable copying press.* Dated March 1, 1869.

The inventor uses a suitable box or case of wood, metal, or other material, and he puts the actuating machinery on each side of the box or case. The necessary pressure is applied by a flat board or metallic plate, which is caused to rise and lower by the motion of the actuating machinery. The mechanism for giving motion to the board or plate consists of a rack and pinion motion, or a screw motion actuated by a worm and worm-wheel or other suitable and well-known mechanism.—Patent completed.

630 B. C. CRAWFORD, Newcastle. *Steam boilers.* Dated March 1, 1869.

The body of the boiler is a plain cylindrical vessel having two ends, which form the tube plates, and in which are inserted, in the usual manner, the ends of the tubes or flues. This cylindrical vessel is intended to be placed horizontally or slightly inclined, and to be nearly filled with tubes or small flues, a sufficient number of which are arranged to act as stays to the flat tube plates, having the requisite water spaces between them. At the upper part a certain space is left clear above the water line to allow of the ready escape of the steam from the surface of the water as it is generated. On the top of the boiler and connected to it is a large cylindrical steam chamber or receiver for collecting the steam and partially superheating or drying it. The furnace or furnaces is or are formed underneath the boiler, having their sides constructed of iron boxes with water spaces formed in them. The furnaces are lined with fire-brick or other non-conducting substance next the fire. The bottom of the boiler thus forms the top of the furnaces, and the fire-bars and grates are carried on bearers fixed to the sides, and provided with ashpits below.—Patent completed.

631 C. E. BROOMAN, Fleet-street. *Spring mattresses and beds.* (A communication.) Dated March 1, 1869.

This consists, first, in an improved construction of mattresses, and in bedsteads for the same, the improvements in mattresses being also applicable to sofas and other seats. Second, in the ties or attachments for binding the springs of mattresses together.—Patent completed.

632 J. G. WILLANS, St. Stephen's Crescent, W. *Iron and steel.* Dated March 1, 1869.

This relates to a previous patent dated March 8, 1866 (No. 702), and February 3, 1869 (No. 326). The inventor has since discovered that granules of cast iron may be made into puddled balls of either iron or steel without reference to the nature of the flame employed, whether the granules be of crude or refined metal or partially or altogether deprived of their carbon. To perform the process he has either the granule so small, say about ⅛in. diameter or substance, or the heat so low (beneath the fusing point of cast metal) that the granules cannot melt into each other before the oxide cinder has so acted upon them as to prevent their fusibility.—Patent completed.

633 W. OLLEY, Enfield. *Circular saw benches.* Dated March 2, 1869.

This consists, first, in the application to the saw spindle of a conical collar which by means of a nut is screwed into the central hole in the saw for the purpose of keeping it tight on the spindle and its cutting edge always at right angles thereto, in order to prevent the saw from working irregularly. Second, in the application to the quadrant at each side of the bench of a fixed bracket or bearing for the shaft of the revolving feeder to drop into, such shaft being held in its place by a block secured by a screw, such block being movable by the withdrawal of the screw in order to release the shaft when required.—Patent completed.

634 J. FARRINGTON, Charles-street, N.W. *Travelling apparatus.* Dated March 2, 1869.

This consists of a light but strong bearing, which is fastened to the leg and extends from the foot upwards if necessary as far as the knee, the distance being regulated by the size of wheel used. This bearing may be placed on either side of the leg. Attached to the bearing is an arm or axle, the position of which is regulated by the size of wheel used thereon, and such arm or axle may be placed on any part of the bearing or foot rest.—Patent completed.

635 The abstract of this specification will appear in our next number.

636 J. HALL, Hounslow Heath. *Horseshoes.* Dated March 2, 1869.

This consists in constructing horseshoes in such a manner that spikes or projections may readily be adapted to them in slippery weather. For this purpose, the inventor drills or bores holes into a horseshoe, and closes up such holes with a metal plug screwed into them, so that the shoe resembles an ordinary horseshoe. In slippery weather these plugs can quickly be unscrewed from the shoe, and screws carrying sharp metal points can be screwed into their place.—Patent abandoned.

637 J. TOWNSEND and P. FORBES, Glasgow. *Oil purifying.* Dated March 2, 1869.

This consists in subjecting the oil or fat to a moderate temperature, so as to expel the odorous constituents, the oil being previously treated first with acid and then with alkali or alkaline earth.—Patent abandoned.

638 J. WOODS, J. HAMPSON, and L. and G. FISH, Preston. *Temples and rollers.* Dated March 2, 1869.

This consists in having the temples on a shaft with a bar of iron or other suitable material in a parallel line or convenient angle with the front edge of the temples, and under the cloth and on the shaft is fixed a small bracket or brackets, which is also fixed to a finger that is bolted to the front carrier, or what is commonly called the breast beam with a stud finger tapped. A cam lever or levers is or are fixed to the lathe or sley, and every time the lathe or sley beats up the cloth it works on the finger or fingers, the cam-tapped lever or levers which is fixed on the front carrier moves or lifts the temples up, and gives a partly rotary or vertical motion to the temples, and causes the yarn to spread, which gives the cloth a better cover.—Patent abandoned.

639 J. HOWE, Boston. *Ships.* Dated March 2, 1869.

This consists in an arrangement of one or more pipes or steam conduits arranged within the body of the hull of the vessel at any convenient or suitable part thereof, and communicating with the steam boiler or boilers of such vessel, the outer extremity of such steam conduits extending through the sides of the hull below the water line and at the stem and stern thereof in such manner and at such an angle to her keel as to enable steam when admitted to the conduit to strike against the body of water with such force and in such a direction as to force the vessel through the water and in the desired direction, the admission of steam to either or any of the conducts being regulated by a cock or cocks suitably disposed.—Patent completed.

640 W. CLARK, Baker-street, W. *Shearing apparatus.* Dated March 2, 1869.

The inventor imparts reciprocating motion to an upper cut plate by means of a lever pivoted on the lower plate and connected with the upper plate by a pin fixed on the latter. The other end of this lever works in a zig-zag cam groove formed on the periphery of a cylinder mounted in bearings at the rear of the comb-plate, or the cam may be formed of a disc or plate bent of the zig-zag form desired.—Patent completed.

641 F. A. GATTY, Accrington. *Treating madder.* Dated March 3, 1869.

This relates to former letters patents granted to the same inventor on 31st March, 1858 (No. 679), and the 9th June, 1858 (No. 1297.) After all the earthy or other oxides have been removed from the fatty compounds by treating them with an acid according to the patents above referred to, dispensing, however, with the boiling with carbonate of soda before the earthy oxides have been removed, the inventor now takes 50lb. of the fatty compound and adds 6 gallons of water, with which it is well stirred. He then adds 9 gallons of caustic soda at 24deg. of Twaddle's hydrometer, and mixes the whole well together, raising the temperature to about 90deg. Fahrenheit, or if the temperature is raised higher a larger quantity of soda is required. The colouring matter is now dissolved, and the soap and other materials are separated from it in the following manner:—The inventor uses strong cotton or linen bags as filters, which are filled with the mixture, and pressure is applied to them in order to obtain as much of the liquid as possible. He then adds an acid (by preference sulphuric acid) until the solution is acid and the colouring matter precipitated; the colouring matter is then collected upon a filter and washed with water until it is free from acid. It may then be dried or used in the wet state for dyeing and printing. In place of soda other alkalies may be used, but it is preferred to use caustic soda. The inventor now takes the solid matter, composed of soap and other materials out of the filter bags, and boils it with from eight to ten times its own weight of a solution composed of common salt at 12deg. of Twaddle's hydrometer, containing from 1-15th to 1-20th part of caustic soda, until the soap has come to the surface. The whole is then left to cool and the soap taken from the top. The liquid still contains a certain quantity of colouring matter in the shape of a gelatinous substance, with which are also combined the impurities of the fatty compounds. The gelatinous substance is separated from the alkaline liquid by filtering, and to the solid or gelatinous portion an excess of sulphuric acid or muriatic acid is added and it is boiled for about half an hour. When cold the solid matter is collected on a filter and washed with water; it may then be used for dyeing and printing.—Patent completed.

642 J. COOKE and G. HIBBERT, Richmond, Yorkshire. *Motive power engine.* Dated March 3, 1869.

The inventor employs two boilers at different pressures. These boilers are connected by a pipe and by a force pump or its equivalent to cause the water and steam to circulate from one to the other. The engine to be driven is supplied with steam or water from the lower pressure boiler, and the exhaust pipe from the engine is connected to a chamber through which the feed and starting water passes. This chamber is connected to the pipe forming the circulation between the boilers, and in this pipe is a chamber for the exhaust steam, which is carried again into the lower pressure boiler by the current of hot water or steam passing through a jet from the higher pressure to the lower pressure boiler.—Patent abandoned.

643 J. SLOPER, Walbrook, E.C. *Perforating machines.* Dated March 3, 1869.

This consists in constructing apparatus for the above purpose, in which a hanging or vibrating lever or frame and a forcing rod or plunger are employed, which are carried and guided thereby and move longitudinally with regard thereto. The motion of the rod or plunger is caused by its action against a cam or cams or inclined surfaces or other mechanical contrivances so arranged as to produce it from the motion of the vibrating lever.—Patent completed.

644 H. W. GOLDRING, Moorgate-street, E.C. *Cotton seed cleaner.* Dated March 3, 1869.

This consists in improved machinery or apparatus for operating upon cotton seed mechanically as well as chemically, and is designed to remove the cotton adhering to the seed. The framing of the machine or apparatus supports a reservoir to contain the seed to be operated upon, a hollow axis working watertight through the ends of the reservoir, and hollow perforated arms closed at their outer ends and forced into the hollow axis. A rigger is fixed on the hollow axis for imparting rotary motion thereto by means of a strap or band suitably driven. Cylinders of sheet metal are mounted loosely on solid axles, to which are affixed brushes. These cylinders are made in two parts lengthwise, the upper part of each cylinder being capable of being moved over the under part thereof. Toothed wheels are employed for imparting rotary motion to one of the solid axles, and brushes are fixed thereon by means of the wheel, over which a chain passes and is suitably driven. A pulley is fixed on the other solid axle for imparting rotary motion to the brushes fixed upon it, which may be effected by means of a strap or band passed over the pulley and suitably driven. An endless travelling band or cloth works over rollers, to one or more of which rotary motion is to be imparted for advancing the driving band at the proper speed. A wiper is used for keeping the curved part of the reservoir clean.—Patent completed.

645. The abstract of this specification will appear in our next number.

646 F. ANDOE, Swansea. *Fire escapes.* Dated March 3, 1869.

The invention consists in constructing apparatus with a box or receptacle for one or more persons to stand or place themselves within, and having cords, ropes, or tackle for suspending it passed through gripping pulleys or rollers, one pair at either end of and near to the top, and thence by other pulleys or rollers guided and brought to pass out of the box or receptacle together, or nearly together, at or near to the bottom, and furnished with a check brake for pressing on the tackle or rollers, or some of them, to prevent too rapid a descent. In some cases the box or receptacle also has attached to it or is fitted or combined with other tackle, including a pulley block for raising the apparatus when desired.—Patent completed.

647 J. ROBERTSON and J. SHANKS, Barrhead. *Smith's bellows.* Dated March 3, 1869.

An ordinary rotary blowing fan is employed, and is driven directly and without intermediate gearing by a belt from a flywheel on a cranked shaft, which is worked by a hand lever and connecting rod. In applying the improved apparatus to fixed forges it is in one modification arranged under the hearth, and the air is led by branch pipes to the tuyeres of two separate fires, the pipes being provided with stop valves, so that either fire may be blown singly or both at once, the apparatus admitting of the two being blown together by one man quite easily.—Patent completed.

648 E. LYONS, Birmingham. *Lamps.* Dated March 3, 1869.

This consists, first, in constructing that part of the lamp called the cap, that is, the outer tube surrounding the wick tube, and delivering air to the outside of the flame, so that the upper part of it has sides parallel to one another, and parallel to the sides of the wick tube. The lower part of the cap on either side is opened outwards so as to form wing-like pieces making a considerable angle with the upper part of the cap. The air collecting under these wings passes up the space between the upper part of the cap and the wick tube, and is delivered in two parallel vertical streams on either side the flame.—Patent abandoned.

649 W. HOWES and W. BURLEY, Birmingham. *Carriage lamps.* Dated March 3, 1869.

The inventors make the chimneys of carriage lamps in two parts, secured together by pressure, the middle flange of the chimney being fixed in its place between the two parts at the same time. By this improvement the chimneys are much stronger than chimneys of the ordinary construction, and are not liable to be injured by the heat of the lamp. Instead of making the holes for the escape of the vitiated air from the lamp in the vertical sides of the chimney, as usual, the inventors make these holes in the top hollow flange of the chimney. By this arrangement the flickering of the flame in windy weather is prevented.—Patent completed.

650 H. A. BONNEVILLE, Paris. *Doubling stuffs and tissues* (A communication.) Dated March 3, 1869.

This apparatus is composed of a table upon which the stuff or article is placed supported by the frame of a metal plate placed above, the width of which progressively decreases, and upon which the stuff or article is gradually turned down and folded by the cover of the apparatus, by passing through an aperture in the length of the metal plate. The apparatus is controlled by regulators worked with screws or otherwise according to the width of the stuff or article and the width of the doubling. On issuing from the apparatus the stuff or article is caught between a series of conveniently adapted driving rollers actuated by any sort of motive power.—Patent completed.

651 W. E. NEWTON, Chancery-lane. *Waterclosets.* (A communication.) Dated March 3, 1869.

This relates to improvements in apparatus for governing the flow of water to and from the basins of water-closets. The water valve is worked automatically and regulated by a retarding cylinder.—Patent completed.

652 R. WRIGHT, Richmond. *Railway carriage doors, &c.* Dated March 3, 1869.

The object is to construct the door of railway carriages in such manner as to prevent injuries to fingers by the closing of the doors. For this purpose, in place of supporting the door on hinges, as heretofore, the inventor supports it on two pins, one at the top and the other at the bottom, and the side edge of the door near to which the pins are placed is made hemispherical, so that when a door is opened this edge is always close up to the door post, so leaving no opening for the people's clothes or fingers to get between them. The opposite edge of the door is provided with a soft or yielding edge to prevent any injuries to fingers if this edge of the door is closed upon them. It is preferred to form the horizontal rails which form the top and bottom of the door to project beyond this elastic edge to catch against the frame of the door and prevent it turning inwards.—Patent completed.

653 D. SWORD, Edinburgh. *Supplying water to cattle trucks.* Dated March 4, 1869.

This consists in connecting cattle trucks or waggons supplied with water troughs to one or more tanks or reservoirs attached to the train, so that by means of affording a continuous supply of water the cattle may drink at any time when on the journey, and the necessity of stopping the train for supplying them with water is avoided.—Patent abandoned.

654 A. A. L. P. COCHRANE, Westminster. *Marine structures.* Dated March 4, 1869.

This consists in the preparation of concrete blocks of gravel or stone chippings, lime, sand, and bitumen, which the inventor combines and incorporates together, and casts, moulds, or otherwise forms into suitable masses or blocks as may be found most applicable for the object in view, both as regards size and weight. These blocks having been deposited, with or without a base or bed of bituminous concrete, in the situation intended, he unites them together so as to form one entire and compact mass by pouring into or otherwise filling up the joints or interstices with a bituminous cement composed of bitumen

sand, and lime in suitable proportions, and rendered sufficiently plastic by the admixture of gas tar together with the application of heat, so as to enable the cement to be poured or run into the joints and to fill them.—Patent completed.

APPLICATIONS FOR LETTERS PATENT.

Dated September 14, 1869.

2680 B. Lakin, Manchester, and J. Bayley, Heaton Norris, Lancashire. Improvements in machinery for preparing, spinning, twisting, and doubling cotton and other fibrous materials.

2681 C. D. Abel, Southampton-buildings, Chancery-lane. A new or improved appliance or apparatus for preventing accidents through the closing of doors and windows.

2682 W. E. Gedge, Wellington-street, Strand. A novel construction of vehicle for locomotion by land and water.

2683 M. Grouse, Southampton-row, Middlesex. Improvements in envelopes.

2684 J. J. Bodmer, Newport, Monmouthshire. Improvements in the manufacture of iron and steel.

2685 W. E. Newton, Chancery-lane. An improvement in pumps.

2686 W. E. Newton, Chancery-lane. Improvements in furnaces and ovens or kilns.

2687 C. C. Steenstrup, New Broad-street, City. Improvements in breech-loading and other ordinance, also applicable to other purposes.

2688 A. H. Gilmore, Edinburgh. Improvements in safety lamps for mining and other purposes.

Dated September 15, 1869.

2689 J. Holding and J. Eccles, Manchester. Improvements in looms for weaving.

2690 H. Allman, Gower-street, Middlesex. Improvements in the construction of ships' compasses, commonly called mariners' compasses, and in apparatus connected therewith.

2691 P. M. Fouque, Boulevard de Strasbourg, Paris. An improved holder for cartridges.

2692 T. Restell, Birmingham. Improvements in breech-loading firearms, and in cartridges for breech-loading firearms.

2693 G. Shaw, Birmingham. A new or improved combined buckle and buttonhole.

2694 G. Shaw, Birmingham. Improvements in stoves and furnaces for burning solid fuel.

2695 W. E. Gedge, Wellington-street, Strand. A novel, instructive, and amusing geographical game.

2696 C. G. Hill, Alfred-street, Nottingham. Improvements in the manufacture of ruches and other trimmings.

2697 W. E. Newton, Chancery-lane. Improvements in machinery for the manufacture of felt and other cloths.

2698 A. V. Newton, Chancery-lane. Improvements in steam and caloric engines.

2699 C. Mohr and S. E. Smith, Birmingham. Improvements in the manufacture of cages for birds, squirrels, and other animals.

2700 A. M. Clark, Chancery-lane. Improvements in key guards, applicable also to the shanks of knob latches.

Dated September 16, 1869.

2701 H. B. Barlow, jun., Manchester. Improvements in apparatus for preventing the incrustation and the accumulation of sediment in steam boilers.

2702 W. Bettison, Liverpool. An improved potters' glaze and seggar wash.

2703 W. Tipping, Wigan, Lancashire. Improvements in apparatus for preventing or consuming smoke.

2704 J. Hampson, Bradford, near Manchester. An improvement in apparatus used in the manufacture of pipes from lead or other metal or alloy.

2705 J. H. Johnson, Lincoln's Inn-fields. Improvements in correcting the deviations of the mariners' compass and dipping needle, and in apparatus employed therein.

2706 C. Eskrett and H. Searle, Kingston-upon-Hull. Improvements in envelopes or hairs used in extracting oil from oleaginous seeds, and oil cake making.

2707 G. A. C. Bremme, Liverpool. Improvements in machinery for breaking and softening flax and other fibrous materials, which improvements are applicable to other purposes where the same kind of reciprocating rotary motion can be usefully adopted.

Dated September 17, 1869.

2708 J. Sawyer, Alma-street, New North-road, Middlesex. Improvements in the construction of furnaces for steam boilers and other purposes.

2709 R. Stone, Liverpool. Improvements in the construction of floors and roofs.

2710 C. M. Waddie, Edinburgh. An improved construction of printing press.

2711 O. H. J. Krag, New Broad-street, City. Improvements in firearms.

2712 A. Collingridge, Moorgate-street, City. Improvements in the mode of stowing and laying submarine telegraph cables.] Dated September 18, 1869.

2713 T. and W. Wheatley, Glasgow. Improvements in fastenings for carriage doors.

2714 R. S. Burkitt, Manchester. Improved apparatus for effecting the combustion of smoke in furnaces or fireplaces.

2715 J. Belicard, Manchester. Improvements in looms for weaving.

2716 H. W. Harman and W. Lancaster, Manchester. Improvements in steam boilers or generators.

2717 M. Amberg, South Seacombe Villa, New-road, Seacombe, Chester. A new or improved instrument for obtaining samples from bales of cotton wool or other wool.

2718 T. J. Denne, Phœnix Works, Cambridge-road, Mile End, Middlesex, and H. Billingsley, Brandon-road, Victoria Park, Hackney, Middlesex. Improved means of producing transfers and blocks for lithographic and other printing.

2719 N. J. Dor, Ampsin, Liege, Belgium. A new method for manufacturing crucibles, muffles, gas retorts, &c., through the agency of hydraulic presses.

2720 C. Belier, Aldermanbury, City. An improved mode of manufacturing binding tapes.

2721 A. Lacanau, Grasse, France. An improved thermo-electric alarum.

2722 H. A. Bonneville, Sackville-street, Piccadilly. New and improved means for utilising the waste arising in spinning vegetable fibrous materials.

2723 H. J. Rogers, Chancery-lane. Improvements in weighing scales.

2724 J. G. Willans, St. Stephen's-crescent, Paddington. Improvements in the manufacture of iron and steel.

2725 W. R. Lake, Southampton-buildings, Chancery-lane. An improved process for galvanising metals.

2726 J. L. Norton, Belle Sauvage-yard, City. Improvements in looms for weaving.

2727 C. Winn, Birmingham. Improvements in machinery for cutting or shaping metals.

Dated September 20, 1869.

2728 S. A. Varley, Roman-road, Holloway, Middlesex. Improvements in electric telegraphs, and in apparatus employed in their construction, parts of which improvements are applicable to other purposes.

2729 J. N. Steiner, Rue de Saintonge, Paris. Improvements in the construction and the propulsion of velocipedes.

2730 J. Polson, Paisley, Renfrewshire. Improvements in treating grain.

2731 A. Tylor, Newgate-street, City. Improvements in water taps and cistern apparatus for preventing the waste of water and for cleanliness.

3732 W. E. Gedge, Wellington-street, Strand. An improved press bed.

2733 M. Doirior, Perigueux, Dordogne, France. Novel vehicles termed velocimanes.

2734 P. Wisdom, Brooklyn, King's County, New York, U.S.A. A machine for twisting and curling hair for use in stuffing beds, furniture, and like purposes.

2735 W. A. Gilbee, South-street, Finsbury, Middlesex. Improvements in apparatus for heating wines and other fermentable liquids, parts of such apparatus being also applicable to other purposes.

2736 C. E. Brooman, Fleet-street. Improvements in the manufacture of chains, and in the apparatus in connection therewith. (A communication.)

2737 W. E. Newton, Chancery-lane. Improved machinery for the manufacture of tape trimmings.

2738 C. E. Schoeller, South Hackney, Middlesex. Improvements in the construction of copying presses.

NOTICES OF INTENTION TO PROCEED WITH PATENTS.

NOTICE.—Having received communications from persons residing in the country to the effect that difficulties are occasionally experienced by them in obtaining copies of printed specification from the Patent Office, in consequence of the varying nature of the postage thereon, our readers are informed that upon receipt from them of particulars of the specifications they require, together with a remittance for the cost and approximate postage thereof, we shall be happy to procure and forward such specifications free of all further charge. Sums under Five Shillings may be remitted in postage stamps, for sums above that amount a Post Office Money Order should be sent, payable to ROBERTSON, BROOMAN, and Co., Patent Department, 166, Fleet-street, London, E.C., to whom all communications upon the subject should be addressed.

THE

MECHANICS' MAGAZINE.

LONDON: FRIDAY, OCTOBER 1, 1869.

THE HARVEY TORPEDO.

THE sea torpedo, invented and perfected by Captain J. Harvey, R.N., is doubtless familiar to all our readers, as it has been frequently brought before their notice in these columns. Those who have followed the history of its development will, with us, be glad to learn that the indefatigable exertions of the inventor and of his nephew, Commander Harvey, R.N., are in a fair way of reaping the well-merited reward of their labours. Not, however, as might have been supposed, by the adoption of the torpedo into the British service, comes this reward and satisfaction to them. Oh dear no! we are too careful, too cautious, and too economical withal, to adopt any invention of national importance until we have allowed some foreign power to forestall us in the matter. It is true our Admiralty authorities made a show a few months since of doing something with the invention. They raised the inventor's hopes and expectations of seeing his torpedo adopted into that branch of the service to which he belongs by instituting a few meagre experiments, which were, however, thoroughly satisfactory. This, however, was only after the matter had been forced upon their attention from a quarter they could not conveniently disregard. But, so far as we are aware, there the matter dropped, and we have not heard of it since. Last week, however, we found Russia investigating the merits of the invention, making the necessary experiments to test its practical value, and taking a large supply of these deadly engines of warfare to Cronstadt.

Should any of our readers wish to know the precise arrangement of the Harvey torpedo they have only to turn to page 189 of our volume for 1867, where they will find a description of the apparatus. Those who are familiar with it need only to be reminded that it consists of a case containing a shell charged with 60lb. of Horsley's powder, which is found equal in disruptive power to 300lb. of common gunpowder. It is constructed to be used against an enemy at sea either by day or night. It has a larger amount of contact surface, and offers a minimum resistance in towing. Its movements are designed to be controlled from a torpedo vessel constructed for great speed. The shape of the torpedo and arrangement of the slings enable the operator to diverge the shell alongside the enemy in passing, meeting, or crossing, according to the plan of attack determined upon. By a very simple arrangement of outside levers and inside discharger, the torpedo is exploded when in hugging contact with the enemy's ship. The addition of a safety key renders the apparatus safe to manipulate. The key is not withdrawn until the shell is some yards astern of the torpedo vessel, so that there is no fear of accidental explosion.

With this deadly apparatus experiments were carried out off Spithead during last week by the Russian frigate "Askold," Captain Kaznakoff. In the first place dummy torpedoes were towed by the frigate in various ways, to satisfy the captain and officers of the certainty of the divergence of the machines, upon which point the most perfect satisfaction was given. In the next place, a smack was provided for attack by a live torpedo containing 60lb. of Horsley's original powder. This was towed under full steam at the rate of about eight knots an hour, but the frigate passing too close to the smack, the rope caught over the quarter, and the torpedo, weighing 2cwt., was whipped into the air. The levers caught in the smack's rigging and were wrenched off, fortunately having fouled the reverse way of their action. The torpedo was thus disabled, but the frigate made a second attempt for practice in handling, fouling this time against the smack, and carrying away her main brace, from again running in too close. On a third trial the frigate got the torpedo fairly to pass under the bottom of the smack, in such a way that explosion would have resulted had the machine been in order. Those who have followed us in our previous articles upon this subject will remember how we have always insisted that this invention was one requiring skilful handling and thorough seamanship, and that the proper procedure was with vessels of small size and few hands against costly and unwieldy ships of war with large and trained crews, in which case the sacrifice of life and property would be great and irreparable, with the least amount of risk in the attack. The results of the trials above recorded exactly confirm the views and opinions expressed by us, and coincide with the course laid down by the inventor for working them. It is, therefore, to be regretted that Commander Harvey, who was on board, had not charge of the experiment with the loaded torpedo for the few minutes necessary for its execution.

The lesson to be learnt from these trials is that it is preferable the tow-line should be carried low by small vessels of swift speed, instead of being triced aloft to the yards of tall-masted ships, whose momentum is very difficult and tardy to control. In enforcing this lesson—which is all important in the use of these deadly engines—we cannot do better than quote a letter which the gallant inventor wrote to his nephew, after the latter had communicated to him the result of the Spithead experiments. Says the Captain:—"The result of the experiment is certainly not such as I had expected. But when the conditions in the conducting of it to obtain a success are just the very contrary to what they should be, there is no difficulty in explaining the misadventure. I was under an impression that you were to have a vessel of some size to operate upon. Had I known that you were to have so small a thing as a smack, I should have had some fear about your tow-rope being too high out of the water to take hold of the hull of so small a craft, knowing that you were not prepared with the proper appliances for managing the tow-rope. In the case of operating upon so small a vessel, there should, I think, have been a lizard so fitted as to have brought the tow-rope down, if desired, near the surface of the water, in addition to a ready means of letting out tow-rope. But, even as it was, had the corvette not passed so close to the smack, I think you would have had an explosion that would have hoisted her out of the water. The error was in being too near, under the condition of your not being enabled to manage your tow-rope to meet such cases. In your tactics you expressly state that a reel and brake are essential to the working of the tow-rope. I quite agree with you, and have, indeed, always insisted upon the necessity of having vessels adapted to the service of the torpedo. The great merit of the arm is to fight with small vessels instead of monsters of enormous cost. A squadron of six, at any rate four, torpedo craft can be constructed for the money expended upon one of our monsters, and to keep such squadron in active service would not, I really believe, be more costly than to keep one monster. Besides which, torpedo craft, of the size proposed, could enter ports which vessels of large draft of water could not enter if in need of repair. I presume the torpedo diverged to your satisfaction. If sufficient divergence is obtained all will be accomplished."

That sufficient divergence was obtained we have already shown, and we are glad to add that, notwithstanding the mischance which occurred, the Russians fully recognise the value of the invention, the merits of which are in no way whatever impaired by the mishap. Captain Kaznakoff and his officers have expressed themselves perfectly satisfied with the results of these trials, and especially so with the principle of the torpedo. They stated that they felt fully competent to carry out other experiments without further assistance from Captain Harvey. It was therefore determined to postpone the further trials of the torpedo until after the "Askold" has reached Cronstadt. She is now on her way thither with a large supply of Harvey torpedoes, which have been manufactured by Mr. W. Nunn, who is well known as having improved the signal lamps of our navy. We cannot suppose that what has succeeded so well here will fail to succeed in Russian waters, so that we next hope to hear of the adoption of the Harvey torpedo by the Russian Government. We confess we see no hope of its adoption in our own country. That is a place wherein a prophet is never accepted.

GAS FROM SEWAGE.

A VAGUE report of some experiments which have been made in India, and which, it is said, have resulted in the production of gas of high illuminating power from sewage, has set numbers of people speculating on the possibility of lighting London from the same source. If this could be accomplished no modern application of science could equal it in importance. It would at once remove a nuisance and convert an enormous waste into profit, and besides that would in London alone save the consumption of something like a million of tons of coal a year. While we are yet in ignorance of the mode of operating which has resulted in the success reported, we can only, with the knowledge of sewage we possess, speculate on what may be accomplished by different methods of treatment. Sewage in London, now well drained and well supplied with water, means animal excreta and household refuse largely diluted with water. What sewage means in India we do not know, but, according to Sir John Thwaites, it is solid excreta. Now the only conceivable mode of obtaining gas from such a material as solid excrement is by distilling it in a retort just in the same way as we do coal; and, as we know the chemical composition of the excrement, it is not difficult to guess what the result of the distillation would be. It would, in fact, be a disgustingly offensive mixture, consisting probably of marsh gas, carbonic oxide, carbonic acid, ammonia, and some other nitrogenized vapours, which would give to the whole an odour to which the smell of burnt feathers would be a perfume. No doubt most of what might be considered impurities in this mixture could be removed, and the two combustibles, marsh gas and carbonic oxide, left alone. But in this case the bulk of the gas would probably be reduced by at least one half; and the remaining half would have no value for illuminating purposes, while it would be highly poisonous. We may say, however, that although we think it highly improbable that any olefiant gas or light-giving vapour would be produced in the process, it is quite possible that some might be present if any kind of fat were found with the excreta.

So far with the treatment of the solid matters. We may consider now how gas may be obtained from sewage diluted with a small quantity of water. Placed in close vessels and allowed to ferment, the result would be the slow production of large quantities of marsh gas, carbonic acid, ammonia, and a few other gases; but, again, the gas would give no light when burnt. If lime were added to

the slush, marsh gas would be obtained more rapidly, and in larger quantities, and no carbonic acid would be mixed with it. If we take sewage such as we have in London, and allow it to ferment, we again procure marsh gas; but neither in this case nor with the slush do we procure gas possessing any illuminating power. We are quite willing to confess our ignorance of any feasible means of obtaining gas from sewage but those we have mentioned above. We shall probably be laughed at by those no better informed than ourselves. Meanwhile, we shall wait for an exact account of the experiments made in India, in the expectation of learning that something more than sewage has been employed. In dismissing the matter until we get the information, it may be worth while to notice what changes the manufacture of gas from sewage in London would necessitate. In the first case we put the use of solid excreta; it would involve the entire discontinuance of our present system of house drainage, and a return to cesspools, or some equivalent for them. If concentrated sewage be used, it means a double system of drainage for every house and the whole metropolis. Lastly, if ordinary sewage be used, it has been calculated from the results of Dr. Letheby, who analysed the gases produced in the fermentation, that to procure the gas required for one day and night in winter it would be necessary to store in close vessels twelve hundred millions of gallons, or more than a fortnight's sewage, which is nearly double the quantity that all the reservoirs of all the London water companies put together would contain.

Some other considerations present themselves, which we may dismiss very briefly. In the fermentation of sewage there is no doubt that various morbid poisons are developed. The poison of fever is generally believed to be derived from this very source, and, according to some, cholera is spread by the same means. A leak in a gaspipe might, therefore, involve worse consequences to a household than result from untrapped drains. But on this matter it is needless to speculate. We say again we wait for information.

THE BRITISH INDIAN SUBMARINE CABLE.

Since our last communication on this subject, giving a description of the enterprise, the work has made such rapid progress towards completion as to render further details necessary. The work to be carried out consists of two long submarine cables, the one of 1,550 knots from Suez to Aden, the other of 2,050 knots from Aden to Bombay, making a total length of 3,600 nautical miles, and forming the longest submarine cable ever manufactured. The lengths we have given are the approximate lengths of cable actually required, including a fair allowance of slack. The whole of the contract for making and laying is in the hands of the Telegraph Construction and Maintenance Company; the core for the cable has been manufactured at their Gutta-Percha Works, Wharf-road, under the able supervision of Mr. Chatterton, and the sheathing of the cable is now rapidly progressing towards completion at their works at Enderby's and Morden Wharves, Greenwich, under the direction of Mr. Clifford and an able staff of assistants. A small portion of one class of cable has been manufactured by Mr. Henley, at North Woolwich. The lengths of the sections being different, two sizes of core have been used. That for the shorter length —Suez-Aden section—consists of a seven-stranded conductor, weighing 120lb. per nautical mile. This conductor is insulated with three coatings of gutta-percha alternating with three coatings of Chatterton's compound, and weighing 175lb. per nautical mile, giving a total weight of conductor of 295lb. per nautical mile. The core for the Aden-Bombay section is slightly larger, the conductor weighing 180lb., and the insulator 240lb. per nautical mile. In this section the conductor is covered with four coatings of gutta-percha alternating with four coatings of Chatterton's compound, the entire core weighing 420lb. per nautical mile. Every care is taken that the copper should possess good electrical qualities, and tests are taken especially with this view, no wire being accepted giving a resistance of more than 11·03 B.A. units when tested at 75deg. Fah. for the Suez-Aden section, and of 7·35 B.A. units for the Aden-Bombay section. This resistance is equal to a conductivity power of more than 90 per cent., as compared with pure copper, the actual conductivity of the wire used being about 93 per cent. Many coils are found to be as high as 96 per cent., and again others higher, but in these cases the extra conductivity is obtained by increased weight. After manufacture, the entire core is kept in water at a temperature of 75deg. Fah. for twenty-four hours, and carefully tested to see that the conductivity of the copper and the insulation of the gutta-percha are above the value given in the contract specification. The figure for the insulation is given at 200 millions ohms. per knot, that is to say, that the actual resistance of a knot length of the material is 200,000,000 B.A. units per knot, or, compared to the smaller conductor, of 18,000,000 to 1. The actual figures obtained during these tests are carefully recorded, for the results obtained at the temperature of 75deg. Fah. are really the most valuable and most reliable of any tests taken during the life of a cable.

After the core has been tested and passed, it is forwarded to the sheathing works, where it is served and sheathed according to the specified type. Now in the present cable, although there are only two sizes of core, as many as six types of external sheathing are adopted. This is rendered necessary by the difference of the coast and the variation in the bottom of the sea. The following list will show the different kinds of cable used:—

Aden-Bombay Section.

Cable Type	D^2	Shore end, Bombay.	10 knots.	
"	E	Intermediate cable	86 "	
"	B^1	Second ditto . .	70 "	
"	C	Main cable . .	1,874 "	
"	D^1	Shore end, Aden .	10 "	
				2,050

Suez-Aden Section.

Cable Type	D	Shore end, Aden .	10 knots.	
"	B	Intermediate cable .	325 "	
"	A	Main cable . .	1,205 "	
"	D	Shore end, Suez .	10 "	
				1,550
			Total length	3,600

Similarly to the plan adopted in the French Atlantic Cable, the different varieties of cable are called type A and so on, and as such we will describe them, thereby making the matter easier and more comprehensible. The shore ends, types D and D^1, are served and sheathed similarly; the core is covered with a serving of jute yarn, steeped in a solution of cutch or other preservative mixture, and sheathed externally with 10 B.B. galvanised iron wires of the diameter of ·375in. (No. 00 B.W.B.), and then protected externally with two servings of jute yarn wound on in contrary directions, with two coatings of Clark's silicated bituminous compound. The served core of the intermediate size, or type B, is the same as the preceding, and is covered with 10 B.B. galvanised iron wires, ·200in. diameter (No. 6 B.W.G.), and protected externally with one serving of jute with one covering of silicated compound. For the main cable, or type A, the core and serving is the same as the previous types, but the sheathing is of a lighter form, consisting of 10 B.B. galvanised iron wires, ·150in. diameter (No. 9 B.W.G.). The cable thus completed is served with two coverings of jute yarn laid on in opposite directions, and covered with Clark's silicated compound.

In the various types of the Aden-Bombay section, the core is in each type served precisely the same, with a serving of jute yarn steeped in a solution of cutch or other preservative mixture. The sheathing in type C, or main cable, consists of nine strands of wire and hemp. Each strand consists of a galvanised best homogeneous wire ·099in. in diameter (No. 13 B.W.G.), surrounded with five yarns of St. Petersburg or Manilla hemp, each strand being passed through a mixture of pitch, tar, and silica before being used for sheathing. The entire cable thus sheathed has further a whipping of seven strands of hemp outside all, but laid in an opposite direction to the wire and hemp strands. The whole is served with a good silicated covering. This form of cable differs from the ordinary type of deep-sea cable in having the outside hemp and silica covering. It is specially adapted to resist the attacks of the "teredo." The outside hemp prevents any opening of the strands, and the quantity of silica used will, it is to be hoped, prevent any attack from these small but dangerous enemies to submarine cables. The intermediate cable, or type E, has, as we stated, the same core as the main cable, but the sheathing consists of 10 B.B. galvanised iron wires ·280in. diameter (No. 2 B.W.G.), further protected with two servings of jute yarn in opposite directions, coated with two coatings of silicated compound.

The Bombay shore end, type D_2, has the same core as the others, is well served with yarn, then coated with a covering of silicated compound, and sheathed with twelve strands, each of 3 B.B. galvanised iron wires ·200in. diameter (No. 6 B.W.G.). The main deep-sea cable and the Bombay shore end show departures from the usual type of submarine cables. In the former, considering the nature of the sea, the plan is an admirable one, constituting this cable the finest specimen we have yet seen of a deep-sea cable. It has the elements of great lasting power. In the Bombay shore end, the application of a hot compound to a served core is new, and we cannot think it an improvement. It would have been better to have made the inner portion of this type similar to the intermediate cable; this, well compounded and sheathed with stranded wires, would have formed a more substantial and lasting cable.

The nature of the course taken by the cable may be briefly stated. The cable, starting from Bombay, proceeds for a little distance in comparatively shallow water; it then suddenly deepens to 900 fathoms at a distance of 140 miles; the depth then increases to about 2,000 fathoms, which is maintained for the major part of the route; at a distance of 600 miles from Aden, the water shallows to 1,500 fathoms; from that point for a distance of 350 miles the depth varies between 1,500 and 1,000 fathoms at 250 miles, and close to Aden the depth varies from 1,000 to 600 fathoms. From the most recent surveys made, the latest being by H.M.S. "Hydra" during last year, the bottom seems well suitable for a submarine cable to rest on. In laying the cable up the Red Sea, the cable will be submerged about mid-sea in the deepest water. This varies from 1,000 fathoms to 300 fathoms, with an average depth over the principal part of 700 fathoms. For the rough parts at the shore end ample provision has been made for strength and for lasting, and we cannot see any reason why the present cable should not last, when submerged, for many years. It is intended to commence paying out from Bombay towards Aden, and then from Aden to Suez; as our readers are doubtless aware, the "Great Eastern" has been engaged for the work, and another success will prove beyond doubt that her mission is the submergence of submarine cables. She will take on board (she is now engaged in shipping cable) the whole of the Aden-Bombay section and a portion of the Red Sea section, the remaining part of the

latter section being taken by the "Hibernia."

The present state of the cable is about as follows:—

Manufactured	Type A	32	knots.
,,	B	325	,,
,,	B^1	63	,,
,,	C	1,742	,,
,,	D	12	,,
,,	D^1	10	,,
,,	D^2	2	,,
,,	E	41	,,
	Total	2,227	

Shipped on board the "Great Eastern," 1,556 knots.

The manufacture has been progressing so rapidly that the "Great Eastern" has taken cable on board quicker than was expected, and in all probability she will have her portion on board and take her departure about the 24th of October. The cable has been manufactured at Greenwich with twelve machines, the whole of which have almost invariably been at work the entire time, without delay or accident, the actual work done being greatly in excess of the French-Atlantic manufacture. The electrical tests of the cable leave nothing to be desired, and the cable when submerged and completed will be one of the finest submarine cables ever manufactured.

The cable when laid is to be capable of transmitting messages at the rate of twelve words per minute on the "Mirror" system, and the contractors are to erect and provide proper and sufficient station buildings, instruments for working the line at the various stations, and deliver the whole to the company in perfect working order. In addition, one month after the completion of the line, the contractors are to hand over their ship "Chiltern" with all her machinery and appliances, so that in the event of any accident happening to the cable, the Company will then have a repairing ship on the station. It will be some months before the cable can be successfully laid, owing to the distance necessary to transport the cable, but on the departure of the expedition we shall place before our readers some details of the manufacture of the British-Indian submarine cable.

The interests of the shareholders are watched over by the engineers to the British Indian Telegraph Company, Messrs. Latimer Clark and Henry C. Forde, and their experienced staff, and these gentlemen will also superintend the laying of the cables and conduct the thirty days' tests after their final submergence. Upon the result of these tests, if found good, the contractors receive their final certificate, and the cable will then be handed over to the company to be worked for the benefit of the shareholders.

THE QUARRYING OF MARBLE.

THERE is a certain class of minerals which require a vast amount of preliminary labour, capital, and perseverance before they can be drawn from their native source and made subservient to the comfort and convenience of mankind. Coals afford an excellent illustration of our meaning. Fortunes have repeatedly been expended before the coal has been "won," as the miners term the striking of a seam that will repay the cost of working it. Tin, copper, lead, and other mines are inseparably connected with visions of long shafts, subterranean galleries, driftways, and headings, not to mention the chances of errors, "faults," and local deviations. Moreover, the majority of minerals must undergo an expensive metallurgical and refining process before they are fit for commercial purposes. The word mining naturally suggests the idea of finding the substance sought for at some depth in the earth, while quarrying evidently applies more appropriately to operations carried on near the surface of the ground. Quarrying, therefore, is free from the risks and uncertainties attendant upon mining, and a very trifling outlay of capital will suffice in the former instance. It must not be imagined that marble comes from the quarry in a condition bearing much resemblance to that in which it meets the public gaze. In many instances it would be difficult for any but a proficient to recognise its individuality. Few would recognise the pure, clean, and white substance that is never absent from the domestic board in the impure, dirty-looking amorphous mass that constitutes rock salt. Nevertheless, in the mass in the mine rock salt multiplies in infinite reflections the surrounding lights, and a salt mine presents to the visitor a scene of almost fairyland appearance. It is rather curious that coal requires no subsequent purification or treatment to render it fit for use, but arrives at the mouth of the pit in a state perfectly fit for the market. All minerals are, to a certain extent, fit for the market when brought to earth, as they are sold as ore, but they cannot be considered in a finished condition until subsequently smelted, reduced, and purified. Many parts of England, Ireland, and Scotland are rich in marbles, but very little is done in marble quarrying at home. We are commencing to ornament our public buildings with this beautiful material, but as yet we do not absolutely use it in construction.

The business of a "marble merchant," if we may coin the phrase, embraces three distinct subdivisions. The first is the quarrying or the procuring of the material, the second the sale in the bulk, and the third the conversion of the raw article into such form as will adapt it for the purposes of ornament and utility. Among the marble quarries of the continent those of the Pyrenees are celebrated both for their extent and the beauty of the article they supply, and it will be interesting and instructive to examine a little into the methods by which it is procured. These quarries are either the property of individuals or of corporations, more generally of the latter, but the usual plan is to let them out to working quarrymen, who, from their want of scientific and mechanical knowledge, are enabled to make but a very partial and imperfect use of the advantages they purchase. They, moreover, cling with that wonderful but inexplicable tenacity to the old system of working which prevailed in the days of their ancestors, and obstinately refuse to believe in the teachings of geology or mineralogy, and the experience of those more fitted to be their instructors. While on the one hand, it is evident that operations conducted almost upon the surface of the earth do not require the same amount of skill and care that must always be bestowed upon deep subterranean explorations, yet on the other it is equally plain that geological and mechanical science may be employed to great advantage.

There are three principal errors into which the ignorance and obstinacy of the quarrymen lead them in the working of the quarries. Of these the most disastrous in its results is the excessive use of gunpowder, or "shots" as they are technically called. To save themselves trouble, the quarrymen roughly trace out by a shallow cut the contours of the block they wish to dislodge, put in the shot, and the explosion gives them generally a huge mass, cracked and fissured in all directions, of the form and shape of which they had no previous idea. Having obtained the block, such as it is, the next step is to "square" it as well as its shape will permit of. To effect this it is necessary to knock off and cut away as much of the material as would form a block equal in cubical contents to that which is left. Owing to this unscientific and extravagant plan of proceeding, nearly three cubic yards of rough block are required to yield one of tolerably squared marble. The above rude method entails a great waste of valuable raw material, a general deformation of the dislodged block, and, what is of still greater importance, a rending and shaking of the whole mass in the neighbourhood of the "shot." It is extremely important here to note the distinction between the quarrying of marble and that of any other ordinary description of stone. In the latter case the more the rock is rent and torn the better, provided blocks of a certain size are obtained, and in some cases the size of the block is of no consequence. All that is required is to "get the stuff," to bring down or blow up the absolute cubical quantity, regardless of its shape and size. But with marble quarrying the very reverse is the case. Not only are blocks of large size wanted, but they must be perfectly sound and free from cracks and fissures. Manifestly if the shot be very violent, it will so shake the surrounding mass that it will be almost impossible to get a good block out of it of the size required. This is a very serious contingency, for supposing that an order is sent to the quarry for several blocks of a certain size, a large amount of labour and material may be wasted before they can be obtained. Granting that by good luck blocks of the dimensions ordered are dislodged, they may be so rent and cracked by the explosion as to be useless except for cutting into smaller pieces.

In whatever light this system of violent "shots" be regarded, it is radically wrong in theory and ruinous in practice, and ought to be at once abandoned for a better and more economical mode of proceeding. The correct method consists in almost isolating the block that has been marked for extraction by deep cuts, so that it is only attached to its parent mass by one of its sides. Its permanent dislodgement may then be accomplished either by means of iron wedges or by a series of small "shots" calculated to produce only the local effect required. If the side by which the block holds on to the rock be situated in the line of least resistance, and L be the length of the side, the charge should be proportional to L^3. By this process, blocks of almost any given dimensions could be obtained, and, moreover, so sound in all parts, that a much higher price would be offered for them than when procured by the system described above.

The second mistake continually committed by the quarrymen is one which is more excusable than that already discussed, but one, nevertheless, which old and experienced hands ought not to fall into. It is a want of judgment in selecting the direction in which the material may be most readily and advantageously quarried, and also in cutting the blocks without sufficient regard to the harmony of their colour and contexture. The extraction and squaring should be so arranged that the greatest degree of homogeneity and uniformity of colour should be in the centre of the exposed faces. The third error of the Pyrenees quarrymen comes under the category of a blunder more than anything else, and would probably never be committed where there was a proprietor or manager of sense and responsibility connected with the works. It is the habit indulged in of despatching for exportation a very inferior description of marble on the same terms as the superior kind. This arises from the want of that proper selection and supervision which would ensure the retention of all blocks that were not "up to the mark," and only allow those to pass which would reflect credit upon the source whence they were procured. Those who have had to do with quarrying, or excavation in rock of any sort, are well aware that the men delight in "big shots." It requires the greatest care on the part of the foreman and overseer in seeing to the charging of the holes, that too much powder is not put in. When the stones "fly," and the report is very loud, one of two evils has been committed. Either there has been too much powder used, or the hole has been "jumped" in the wrong direction. A great

deal depends upon the manner in which blasting operations are carried on. A railway contractor that had a heavy rock cutting to get through would find it a losing job if he entrusted the excavation of it to any but a "ganger" who was an old hand at blasting.

TELEGRAPHIC NOTES.

THE example set by England in the matter of Government and the telegraph system appears likely to be followed in America, for we learn that the Western Union Telegraph Company of New York, which has absorbed all the other leading lines of the country, is likely to press upon Congress, at its approaching session, the propriety of the Government buying them up and carrying on the business after the English precedent. This enterprise was established about twenty-three years since by Professor Morse and some other gentlemen. It commenced operations with a single wire from Baltimore to New York. Its capital stock now, however, represents a sum equal to about eight millions sterling, besides a bonded debt of nearly a million. The company, under their charter, have the power of purchasing competing lines at pleasure, and it is by issuing stock for that purpose and also to patentees that a great part of their enormous nominal capital has been created. It is stated that in past years this company has been "a source of alleged fraud and corruption, as it has been charged that parties of controlling influence have bought up the stock of comparatively valueless lines at merely nominal figures, and officially turned the same over to the company at much larger prices and often at greatly more than they were worth, to the great damage of the company and to the profit of the officers directly or indirectly engaged in the transaction." At the present time, the company's plant and stock includes 3,462 stations, 52,099 miles of poles, and 104,584 miles of wire, which traverse every State and territory in the Union except Minnesota and New Mexico. The receipts last year were equal to about £1,460,000, and the net revenue was about £550,000, or about 6¼ per cent. on the capital stock. The company contend that the terms at which the Government should buy them ought to be calculated on the assumption that a 10 per cent. stock may be considered worth par, and that their stock, paying 6¼, should be taken over at 65. It is remarked by the Philadelphia "Ledger" that this mode of valuation would be very well if the company possessed any considerable real property for its capital and indebtedness, or if the exclusive privilege for which so large a portion of this capital was expended still continued to the company. But it appears that the patents have expired, anybody may put up lines, and more cheaply, and the present poles, wires, and insulators now in use are gradually falling into decay. At the same time, while the company take an opportunity to remark that, "based on the proposed purchase of English lines, the valuation for their system would be £11,200,000," it is pointed out that the reasoning in this respect is also deceptive, since there can be no just comparison of the lines of the Western Union Company with the English or European lines, the qualities of the wire, poles, insulators, and other materials used in America being very inferior, as everyone knows who has seen them.

The collection and supply of telegraphic intelligence to the various London and provincial news-rooms, chambers of commerce, and the press has hitherto been, and at present is, effected by the various telegraph companies. In a public point of view, this is one of the most important functions of the Electric and International Telegraph Company, but, on the transference of the wires to Government, the existing arrangements for the collection and supply of news will cease. In view of this the Home and Foreign Telegraphic News Company (Limited) has been formed for the special purpose of taking up and carrying on the intelligence department of the telegraph system as at present conducted. It is intended to secure the services of a portion of the working staff of the present intelligence department, and the whole, we are informed, will be under the direct personal superintendence of a gentleman who has not only for the last thirty years been engaged in this special work, but who has been intimately connected with the intelligence department of the telegraph ever since its first establishment. Arrangements are in progress for obtaining the co-operation of several of the most important news agencies in London, Liverpool, Manchester, and New York; and for establishing agencies at each of the European capitals, and at all the other chief centres of mercantile intelligence in Europe, India, China, and the colonies; so that by the time the transference of the wires to her Majesty's Post Office authorities takes place, it is expected that this company will be in a position to supply, irrespective of all other sources, original and early news on a more extended scale, and on a system of greater efficiency, than has hitherto been attempted.

Another telegraphic company is announced under the name of the Oceanic Telegraph Company (Limited), Ireland to Nova Scotia direct. The stated object of this company is to provide cheaper and more direct ocean telegraphic communication generally; in the present case, by a direct line from the south-west coast of Ireland to Sable Island and Halifax, Nova Scotia, which is in complete telegraphic communication with New York and America generally. The company's operations are based on a system of deep-sea telegraphy, admitting the selection of that route which is free from the risks of icebergs and anchorage, and enables the line of communication to be most cheaply constructed and laid, "releasing the telegraph world from its utter dependence on a 'Great Eastern,' and effecting a saving of 40 per cent. on first cost, with extra working capacity." Another material feature in the adoption of this route is that it is a through route, and avoids the dangers to which the present is liable.

Telegraphic communication between London and Australia may be anticipated at no distant period, as there are now only one or two short sections requisite to complete the circuit between Sydney and London. It is estimated that that portion in which Australia is chiefly concerned, namely, from the Gulf of Carpentaria to the Island of Java, a distance of 1,900 miles, could be laid for £500,000. Application has been made to the Government of Dutch India for a concession to land a cable on the east coast of Java, to connect Australia, under a subsidy or guarantee. It is proposed to ask from the Governments of the Australian colonies a guarantee of 7 per cent. on a moiety of the cost of construction, and the amount which they would be asked to contribute is set down at £17,500. The proportion payable by New South Wales would simply be £4,375, in the event of the traffic not paying a dividend of 7 per cent. over and above the working expenses.

We regret to find that a fresh injury has been sustained by one of the cables of the Atlantic Telegraph Company. The accident which has caused the parting of the cable has occurred about 70 miles from Heart's Content, near the locality of the former fractures of the line. The injured cable is the one laid in 1866. Fortunately, the communication between the two countries has not been interrupted by the accident.

In the United States there are 4,126 telegraph offices, or one for every 7,549 of the population, and nearly every town and village has its office. Over 50,000 miles of line, and 100,000 miles of wire, with 265 submarine cables, are in operation.

The number of messages which passed over the French Atlantic cable for the week ending September 25, was 686, the cable charge thereon being £1,797, showing an increase of £474 over the previous week.

According to the "Russian Exchange Gazette," M. Kumbari, a merchant of Odessa, is now engaged, together with the governor-general of that town, in making preparations for the construction of a submarine telegraphic cable from Odessa to Constantinople.

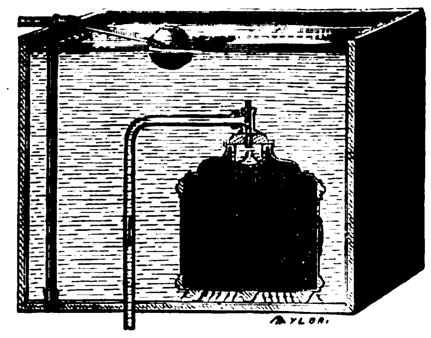
A line of telegraph has been completed from the Land's End to St. Mary's on the Scilly Islands, thirty-one miles, by which means the receipt of shipping intelligence will be much accelerated. The undertaking has been effected by a few private subscribers.

THE following statistics relating to the woollen manufactures in Italy are taken from a book recently published by Sig. Alessandro Rossi, entitled, "Dell' Arte della lana in Italia, ed all' estero guidicata all' Esposizione di Parigi, 1867." The number of persons of both sexes employed in the woollen manufacture in Italy is 25,000. The wages range from 70c. to 3f. 50c. per day. The number of spinning-frames throughout the kingdom is 673, and 6,480 looms. The following is the value of the annual consumption, production, and importation of woollen stuffs in Italy:—Consumption, 170,000,000f; production, 74,280,000f; imports, 86,685,290f.

A REMEDY FOR IMPURE WATER SUPPLY.

ALTHOUGH everyone using the London water supply can testify to its impure character, it is but just to the London water companies to state that they have done what they could towards effecting its purification. They have incurred heavy outlays in providing filter beds, and in constructing covered reservoirs for storage. By these means they succeeded in slightly diminishing the hardness of the water and in reducing the amount of organic matter held in suspension. But it is absolutely necessary to the health, both of individuals and of communities, that the organic matter should be entirely removed before the water is used for domestic purposes. It is hardly possible to effect this by any amount of filtration upon the ordinary principle adopted by the water companies, and it is a fact patent to all that the London water supplies are still contaminated by impurities. The Plumstead Company, it is true, who draw their water from the chalk formation, use Dr. Clarke's softening process, which leaves only 8½deg. of hardness. This compares well with the other waters of London, which average 20deg. to 22deg. of hardness, with 2·60deg. of organic impurity. But the Plumstead Company is the exception, whilst the other companies form the rule which has now to be dealt with. Of course a complete remedy for the evil would be a total change from the Thames to purer sources of supply, as has been done by the Plumstead Company. But, pending this, we must adopt a system of domestic filtration, by which means every consumer can purify the water required for his own use on the premises. This can only be effected by filtration through animal charcoal, which is unquestionably the best substance for the purpose.

There are various kinds of apparatus for effecting filtration, but which, for the most part, require frequent attention in filling, and even then they do not afford a constant supply for all purposes. The best plan with which we are acquainted is that advocated by the London and General Water Purifying Company, of 157, Strand, who have certainly hit upon a very perfect remedy for the impure water supply to which we have to submit. This consists in placing the filter inside the source of supply—the cistern,—and so arranging it that every drop of water must be purified before it is drawn for use. The system adopted is shown in the annexed cut; it is the Danchell filter, which is filled with animal charcoal, and operates by ascending currents. By this means the suspended



impurities are separately precipitated outside the filter, whilst those only which are held in solution pass into the filtering medium. The water becomes purified from these latter in the act of ascension through the animal charcoal. By this arrangement it will be seen that the mechanical impurities, which would otherwise clog the filtering material, are not allowed to enter the apparatus, a point of very great importance in connection with its durability. The system further affords the greatest facility for removing those impurities which are held in solution in the water, and which are intercepted within the filter. This system of filtration is not noticed here as a novelty, for the London Water Purifying Company have supplied these filters to the public for the past six years, and with very best results. But, having the experienced the inconvenience of the hardness, and having incurred danger from the impurity, of the London water, we have adopted one of the Danchell filters in our cistern. This has been followed by such excellent results that we think it only due to the public, who are subject to the same conditions of impure water supply, that they should know how the evil may be effectually remedied.

STATISTICS OF INVENTION ILLUSTRATING THE POLICY OF A PATENT LAW.*

By Henry Dircks, C.E., LL.D., &c.

THE time seems to have arrived for a closer inquiry into the policy of a patent law than the subject has hitherto obtained, for in all probability a parliamentary committee or commission will be appointed next session to take evidence in reference to the working of our present system of patent laws; and the matter has already been agitated by the working classes (particularly at a conference presided over by Sir Roundell Palmer), who consider their interests would be at stake should certain proposed measures be adopted, as suggested by a small but influential party who denounce patent law as an interference with the natural rights of man, and consequently retarding all improvement in arts, mechanical science, trade, and commerce. In fact, if we are to believe all we hear, patent laws never have had and never can have any other than an evil tendency, when considered in an enlightened point of view, for the benefit of mankind at large. The question whether patent laws are to be retained and reformed, or whether they are to be abolished, can only be satisfactorily answered by tracing historically and statistically what have been their results hitherto.

In the first place, it is quite clear that heavy patent charges act on the patent system like heavy duties on commerce—excessive fees become prohibitory duties, patents fall off, as only men of ample means can afford to procure them. Hence the history of patented inventions from the period of Queen Elizabeth to that of the present reign dating to October, 1852, is meagre in the extreme. Therefore, for no less than four hundred years Great Britain and Ireland were, if not completely, yet certainly very nearly approaching that happy state desired by the patent law abolitionists. The number of patents per annum was so exceedingly small that their influence on the arts and sciences and commerce of this country must have been infinitesimally little. But in what respect were manufactures benefited? What were the great inventions of the age thus indicated? Let an answer to such queries be given after a careful investigation of the mechanical and other treasures of the Kensington Museum.

When we consider guns and gunpowder as unpatented inventions of the thirteenth century it may be some consolation to opponents who see in unimproved inventions, in inventions in their infant state, all that man need desire. Or, in the same mood to revert to block printing, introduced by Gutenberg in the fifteenth century, a second splendid and unpatented invention. The waste period between is never considered, nor even the obvious stagnation of all improvement. Progress there was none—that is, as we consider progress, and yet, if patent law abolitionists expect to find vantage ground on such wild assumptions as these and similar instances afford them, it is very evident how indefensible their arguments are when thoroughly scrutinised. The ground was then so barren that the seeds of scientific knowledge refused to germinate on its ungenial surface. It is true the elements of modern progress were not wholly unknown—not even those of the steam engine, about the middle of the seventeenth century—but there was a decided torpor everywhere, all was stagnation, and as to inventors and inventions they were all equally reproached and stigmatised.

In October, 1852, the present improved patent laws came into operation, requiring only one process to include protection throughout the United Kingdom of Great Britain and Ireland, instead of being split into three; also reducing the patent fees, and making them payable by three instalments, namely, for three, four, and seven years, being a total of fourteen years. The result of this great change in the system of obtaining and paying for patent protection has been absolutely prodigious—so much so, indeed, that it would be impossible to point out any other than a constant increase in the trade and commerce of the country. A good invention commands capital, and capital its usual encouragement and spread of civilisation. A man need no longer be in a state of wretchedness, want, and misery, who possesses a novel, simple, and practical invention. Is he a humble working mathematical instrument maker? See how Boulton took Watt by the hand, dedicating his whole fortune to promoting the success of his steam engine, and that, too, in the face of Smeaton's declaration that he was convinced that Watt's engine "could never be generally applied as a useful agent;" for prejudice and shortsightedness always track the path of inventive genius. Mr. Young, holding in early life a very subordinate situation in a chemical establishment, now finds himself the possessor of great wealth, returning as his net proceeds in one year the immense sum of £300,000 derived from his manufacture of paraffin oil.

It is supposed that very strong arguments for the abolition of patent laws are offered by the suggestions, first, that the inventive faculty is innate in man, and so prolific and exciting that it must germinate under the most adverse circumstances. And, secondly, that, although in the infant state of arts and sciences patent laws may have served to foster inventive talent, such is their present growth and vigour that we may safely cast away all such nursery appliances. Indeed, Mr. Macfie, M.P. for Leith, thus plainly puts the case.

Now, as regards the first statement, it is quite true, so far as concerns the mere simple fact of invention, whether in literature or in science. Under every disadvantage invention will exist in some form or other, and may even slightly progress. But what kind of a crop shall we reap? Was ever any great invention brought to maturity without laborious experimental research, and without a large expenditure of capital? Next to printing, what invention has been of more utility to mankind than the steam engine? What would be the present state of society without it? And yet if we trace its history ever so briefly we perceive from what feeble efforts its present gigantic strides have arisen, permeating every class of industrial arts, and spreading far and wide the inestimable blessings of civilised life. Now if we look at an invention in its state of maturity it is like admiring a stupendous oak, and overlooking its having once been an acorn. To what can we trace the encouragement that has stimulated inventor after inventor to toil with mechanical and other inventions, amidst all the opprobrium that prejudice can cast on him, as his being a speculator, schemer, and fanatic? Undoubtedly he looks forward to fame and fortune, and no process so easily secures these to him as patent law; not that the present laws are perfect—far from it; but because any law is better than no law; and every inventor finds himself surrounded less by friends than by men ever ready to adopt his ideas (if found to be of any value) without the least compunction at leaving him to starve in adversity, as was the case with Henry Cort among wealthy ironmasters, and has been the lot of hundreds of other estimable inventors.

But as statements unsupported by facts are of little value, we select the progress of that great invention, the steam engine, as sufficiently illustrative of the importance of a patent law, merely premising that the modern term steam engine is one applied to an old invention, indicative of its progressive improvements. Thus, first, in its primitive state we find the following inventors, under the respective dates annexed to them:—1663, Marquis of Worcester; 1683, Sir Samuel Morland; 1698, Thomas Savery, F.R.S. Secondly, as an atmospheric engine: 1698, Dr. Denis Papin; 1705, Thomas Newcomen; 1718, Henry Beighton, F.R.S.; 1720, Leupold; 1736, Jonathan Hulls; 1739, Bernard Belidor; 1741, John Payne; 1751, Francis Blake, F.R.S.; 1757, Xeane Fitzgerald, F.R.S.; 1758, William Emerson; 1759, James Brindley; 1762, Dr. Joseph Black; 1765, John Smeaton, F.R.S.; 1766, John Blakey. Third, as the steam engine proper: 1769, James Watt, LL.D., F.R.S.

We have thus gone over a period of 106 years, and find that from the introduction of the first engine twenty years elapsed before a second one appeared, and from its date fifteen years elapsed before the third and fourth were made known; a fifth then follows after a lapse of seven years, a sixth in thirteen years, a seventh in two years, an eighth in sixteen years, a ninth in three years, a tenth in two years, an eleventh in ten years, a twelfth in six years, and afterwards at stages varying from one to three years. Now such was the state of invention as a national boon under what we may term the restrictive duties of high patent law fees, say from £300 to £400 for the United Kingdom, showing only eighteen inventions, all relating to one and the same object—the application of steam as a mechanical agent—spread over more than a century, when at length we arrive at the true and complete steam engine, superseding all its predecessors. Here is nothing problematical. We all know that the Marquis of Worcester spent a fortune in bringing his water-commanding engine to a sufficiently practical bearing to have it in public use for seven years raising water at Vauxhall. Unless he had been protected (in his case by an Act of Parliament) he would never by his example have stimulated, as he no doubt did stimulate, many succeeding inventors to follow in his footsteps. It is singularly absurd to presume that without the slightest legal protection inventors will give to society the suggestions they arrive at and the arduous labours necessarily imposed upon them, and it is remarkable that any one should suppose that an unworked idea is tantamount to an invention brought to a practical bearing; whereas what we see is the nature of the progress that has been made in the development of the steam engine, is precisely that which applies to all inventions whatever; and it would not be too bold an assertion to say that the principle of the steam engine proper might as well have been found out and in practice fifty years or more before the time of its great application by Watt had patent laws undergone earlier revision, and been as liberal to inventors as in our day. For at the rate of only one new engine per annum, there would have been 106, instead of only eighteen inventions for that long period; and in such cases number is absolutely indicative of the state of progress.

The second statement alluded to presumes that the present age of invention may be looked on as having arrived at maturity. Genius no longer requires nursing. Perhaps at no age of the world would mankind have felt disposed to believe otherwise than that the age was most polished and civilised, and yet age after age what revolutions take place! Are patent abolitionists who cherish such notions prepared to show that chemistry can make no further advances, that mechanical science is exhausted, and that no department of industry requires aid from inventors beyond what they have already acquired, and that for the future their services will be so light and unimportant that medals, or honourable mention, or a Government reward will sufficiently compensate them for all their mental and physical labours? As, however, it is unnecessary to dwell on arguments which only prove the weakness of the cause they are intended to support, it will be to greater advantage to point out what is really wanted for proving the impolicy of a patent law. It is always understood and believed that patented inventions introduce new manufactures, or improvements on old manufactures; also that they are labour-saving, or more productive than ordinary processes; and, finally, that in every instance they are so productive and economic that the public at large derive from them, either directly or indirectly, the greatest possible advantages. If the reverse of this representation can be shown—if trades or manufactures suffer, then nothing can be easier than to prove the facts historically and statistically. But one recommendation remains to be given to all patent abolitionists—who find inventions to be only ideas, and that ideas for improvements are the cheapest and easiest imaginable of mental processes—to turn inventors themselves, or bring up a school of inventors so as to be enabled to supersede one patented invention after another by their free gifts of such superior inventions as shall throw all patented ones in the shade, and to obtain from society their full meed of praise for their patriotic measures and thoroughly practical proceedings.

Manufacturers find that patent law fosters the decided inconvenience of introducing an amazing amount of competition; and competition, too, of a kind that even the oldest establishments cannot withstand, or the largest capital extinguish. Again, between patentees, patent laws are far from being all that they could desire, for while appearing to protect an original inventor in the matter of his invention, they afford to every petty improver an amount of protection equal in value, so that the giant and the infant are virtually placed on an equality with each other. But, as regards the public—the million—they, comparatively, know nothing about patents—they never purchase them, and scarcely ever see them, and are utterly unaware whether patents ruin, interfere with, or enrich trade; their only experience is, that the prices of all the manufactures they purchase are periodically purchased at declining prices, never concluding, however, on that account that the posperity of the country arises from the losses of their manufacturer on such patented articles of general consumption.

* British Association.

There was an eruption of Mount Etna on Sunday last, when two torrents of lava were flowing down its sides.

GUNPOWDER PILE-DRIVER.

BY MR SHAW.

FIG. 1.

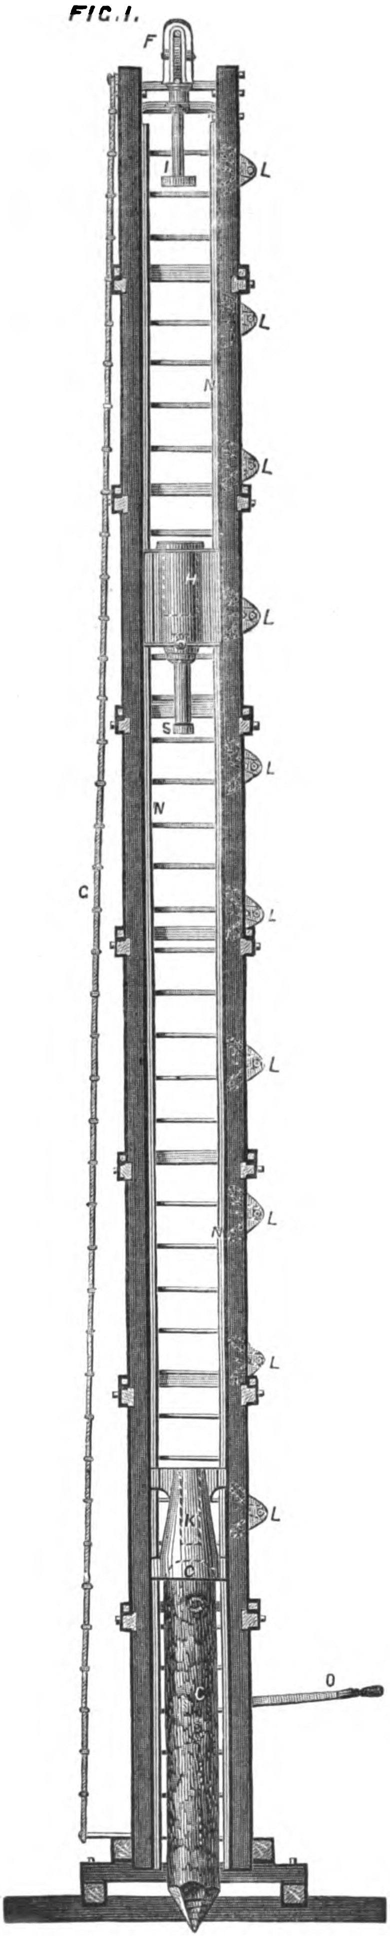


FIG. 2.

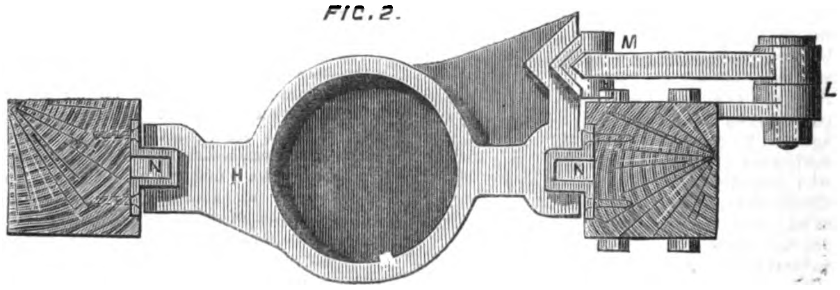
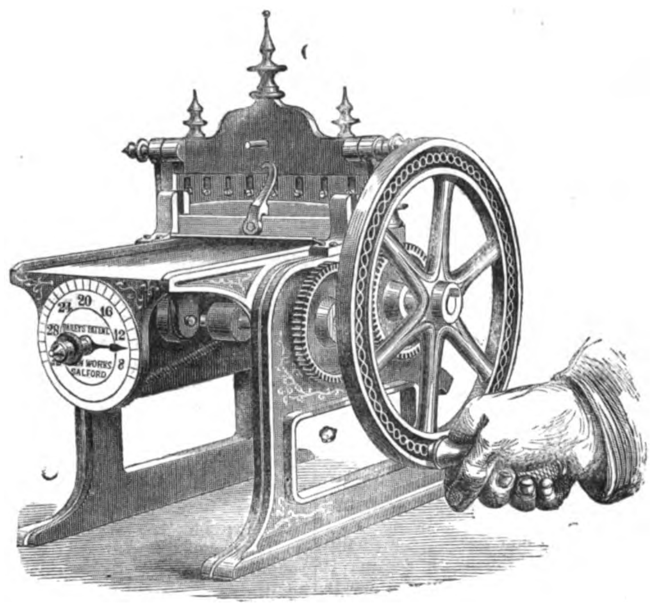
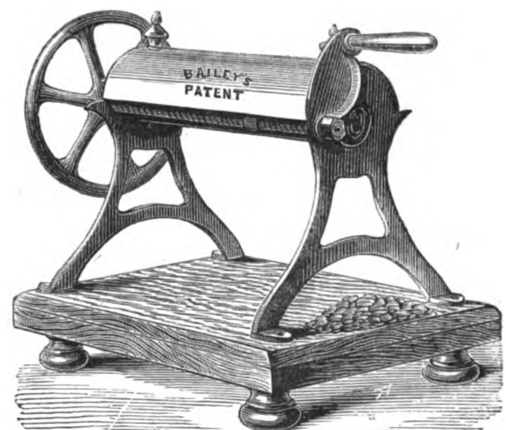


CAVENDISH CUTTERS.

BY MESSRS. J. BAILEY AND CO.





BAILEY'S PATENT CAVENDISH CUTTER.

THE annexed engraving illustrates a useful apparatus which we found at the Royal Agricultural Society's Show at Manchester. It is an adjustable and indicating feed Cavendish tobacco-cutting machine, and was exhibited by the inventor, Mr. W. H. Bailey, of Salford, Manchester. The general construction and working of this machine are seen from our illustration. The thickness of the cut may be instantly adjusted from 1-8th to 1-32nd of an inch. These thicknesses are indicated on the dial in front of the machine. The cutter is perfect in its action; the ease with which different degrees of fineness of cut can be obtained was demonstrated at the Manchester Show. Besides the above, Mr. Bailey has brought out another cutter for cavendish roll, which we also illustrate. It consists of a frame in which is a tube, having a screw on the side which, when turned, forces the tobacco to the mouth. A knife is attached to the end of the screw, and which cuts off a slice at each revolution. This machine is neat in appearance and efficient in action. It is patented in this country and America, and is manufactured by Messrs. J. Bailey and Co., of the Albion Works, Salford, Lancashire.—"Tobacco Trade Review."

SHAW'S GUNPOWDER PILE-DRIVER.

IN our issue for July 30 last, there appeared an interesting letter from Mr. Hector Orr, of Philadelphia, giving particulars of Mr. Shaw's gunpowder pile-driver and some trials of its powers. We think that letter will be well supplemented by the accompanying engraving of the pile-driver, and to which the present description refers. The machine is constructed of heavy wood framing, as in the ordinary pile-driving machine, and is provided with a cylinder head of cast iron K, resting on the top of the angle C, and guided by the iron rails N; the cylinder is bored out on its uppe end for the reception of a plunger S, of the ham mer H, and is cast concave on its lower end fo the reception of the pile C. The hammer H i guided by the rails N, and is bored on its uppe end for the reception of a piston I. It is cast wi a V-groove for the reception of a friction rod M, fi 2. The piston and rod I are connected with a cr beam, firmly fixed at the top of the frame, whe a rope pulley F is also placed for the convenie of hoisting the piles into position. The fricti

rod M is connected with the starting lever O, and also with short cast-iron arms pivoted to brackets L, figs. 1 and 2, for the purpose of pressing tightly against the V-groove in the hammer, as shown in fig. 2, whenever the hammer moves in a downward direction. A ring is made of steel and screwed on the end of plunger S; this ring, though of solid steel, expands under this pressure, the same as hydraulic packing, and makes a tight and durable packing.

The machine is operated and controlled by a man and boy; the latter is stationed at the rope ladder G, and throws a cartridge of powder into the cylinder K, when the hammer is allowed to drop by the man's pressing upon the lever Q, which elevates and releases the friction rod from the hammer and causes it to drop, forcing its plunger into the cylinder, compressing and heating the air contained therein sufficient to ignite the powder whenever the plunger comes in contact with the cartridge and tears the paper, so that the heated air may come in contact with the powder. The explosion of the powder elevates the hammer, and the recoil of the cylinder forces the pile into the ground. When the cartridges are thrown at the rate of fifty per minute, the hammer is operated without the use of the lever, except when desiring to cease operating. The object of the air cushion at the top, formed by the bore in the hammer H and piston I, is to prevent a heavy charge from injuring the machine.

The powder employed is of the most simple character, being composed of one and a half parts chlorate of potash and one part of bituminous coal, both pulverised and mixed through an ordinary sieve. This powder burns very slow in the open air; a barrel full might be ignited at once without causing any report. The charges of powder are exceedingly small, a charge of one-third of an ounce being employed to throw a hammer of 675lb. weight, and it is stated by the "Scientific American" that it exerts a force on the head of the pile equal to a dead weight of 300,000lb. for a temporary period. The pressure is exerted on the head of the pile during the presence of the plunger in the cylinder; this gives a blow and pressure of the character of the hydraulic press with the rapidity of the hammer; hence the pile can be driven more rapidly, and forcibly, and firmer, without in any way injuring or splintering it, as in the common method of driving. The usual wrought-iron ring, secured to the head of the pile preparatory to driving, is in this method entirely dispensed with, and it is estimated that even this trifling advantage will nearly pay for the powder employed.

A committee of engineers, composed of W. W. Wood, chief engineer of the United States Navy; H. L. Hoff, of the Eagle Ironworks, Philadelphia; and T. J. Lovegrove, inspector of steam boilers, Philadelphia, appointed to investigate the operation of this invention, give a most flattering report, indorsing fully all of the above statements.

THE TENTOONSTELLING.

THOSE of our readers who have not recently visited Holland and who is not familiar with the language of its inhabitants will naturally first like to be informed of the meaning of the above word. The Tentoonstelling, then, is the international exhibition now being held in the Crystal Palace at Amsterdam, and which is of the greatest interest to the manufacturing community. The time of its closing draws near, but there still remain a few weeks during which a visit can be made. But, as this is not practicable to all, we will tell them the next best thing to do. This is to go to the Polytechnic Institution, where they will find Professor Pepper, who has just returned from Amsterdam, and who has prepared a most interesting lecture upon the exhibition there, which he has been studying for that purpose. The Professor is always instructive as well as interesting, and, in the present instance, he combines both qualities in a very happy manner. He first advises those who have not yet made their holiday trip to go to Amsterdam and see the Exhibition and the city. He gives ample instructions to tourists,and is a very "Bradshaw" in the matter of routes and hotels. He then introduces his audience to the Palace itself, which is an elegant building of iron and glass. It was built some six years since from the designs of Mr. Outshoorn, a Dutch architect, Mr. Ordish, C.E., of Westminster, having worked out the engineering details of the structure. By the aid of some highly effective dioramic pictures, we have exterior and interior views of the fine building and its contents, which are all fully explained by the Professor. The costumes of the country are also illustrated in the same way, as are also some of the chief pictures in the galleries of Amsterdam. The exhibition is purely industrial, but Amsterdam abounds in rare paintings, and the introduction of these adds an agreeable feature to the lecture. Besides all this, we obtain a very good insight into the city itself, its buildings, its manners, and its customs, by the same means of illustration and description. Altogether Professor Pepper's new lecture gives an excellent idea of the Exhibition, the country, and the people, and should be attended by everyone who has a shilling and an hour to spare any morning or evening. We may add that the other lectures continue to be equally attractive. The Great Lighting Inductorium, upon which Mr. Thomas Tobin, the indefatigable secretary to the Institution, is now lecturing, always commands a crowded theatre, whilst the mysterious hand—taught by the same gentleman to answer in writing questions put by the audience—has constant demands upon its caligraphic powers.

THE FRANKLIN EXPEDITION.

THE week before last we announced in our naval items the publication in an American paper of a letter respecting Sir John Franklin's expedition. Later intelligence supplies the following further particulars in the shape of a telegram dated San Francisco, September 13. A party, vouched for as reliable, writes to the "Bulletin," from San Buenaventura, that a document had been found on the beach at that place on August 30, very badly mutilated. On the document was found a request for the finder to forward it to the Secretary of the Admiralty at London, or the British consul at the nearest port, the request being written in six commercial languages on the margin. Every vacant portion was filled with writing relative to Sir John Franklin and his party. The document was evidently cast in the water in lat. 69deg. 37min. 42sec., and long. 98deg. 4min. 5sec. It gives an account of the desertion from the ships "Erebus" and "Terror." The party numbered 105 at the time of the desertion, under the command of F. R. M. Crossier. They had succeeded in reaching the above latitude and longitude, where they had found relics of the late Sir John Ross. The document states that the party had wintered at Beechy Island in 1846 and 1847, and that Sir John Franklin had died on June 11, 1847. It contains many interesting incidents connected with the expedition.

COOPER'S METHOD OF STREET WATERING.

MR. NEWMAN, the superintendent of street cleansing, &c., of Liverpool, has just issued his report to the Health Committee upon the trials made during the past season of Mr. Cooper's street watering salts. The main thoroughfare along Lord, Church, and Bold streets, chiefly macadamised, is considered to have afforded as severe a test as possible from the heavy traffic over it during the hottest period of summer. It is stated in the report that the use of these salts has been entirely successful, and beyond comparison superior to plain water. In practical results two water carts with the weak solution were found equal to seven under the old system upon the macadamised road; but in paved streets one may be expected to do the work of five where the traffic is only ordinary. Financially, notwithstanding the saving of horses and carts, it appears that, at the price of £3 per ton hitherto charged for the salts, no economy can be effected; but then the supply has so far been in experimental quantities, and it should be stated that the patentee is now prepared to deliver in quantity at forty shillings. It is further considered that a reduction of 70 per cent. would be effected in water wasted in the streets, and that there is the collateral advantage of the surface of the roadways being maintained in superior condition, a saving of 20 per cent. in the cleansing being due to this effect. The system has also been tested in Greenock, and is reported upon equally favourably by Mr. Barr, C.E., the master of the works.

A TELEGRAM from Suez announces that the water having been admitted into the Bitter Lakes, the required level was obtained throughout the entire length of the Suez Canal, and that a steamer with M. de Lesseps on board has made the passage from Port Said to Suez in fifteen hours.

COAL IN PENNSYLVANIA.

THE coalfields of Pennsylvania supply nearly all the anthracite coal produced in America. They have been worked only for a comparatively short time; so late as 1812 they were unknown except by a few geologists. The coal region is divided into three sections—viz., the Schuylkill or southern district; the Lehigh or middle district, and the Wyoming or northern district. The product of these regions last year amounted to 13,405,016 tons. The bituminous coalfields of Pennsylvania, Maryland, and Virginia yielded over 2,000,000 tons more, so that altogether the quantity of coal mined in 1868 was upwards of 15,000,000 tons. In mining this amount, upwards of 35,000 people were employed. These are chiefly English, Welsh, and Irish, the last being mostly unskilled labourers, and the first two those more or less acquainted with mining. These operatives live generally in houses belonging to the companies, have their fuel for nothing, and, before the present strike commenced, earned as miners from 5dol. to 6dol. a-day, and, as labourers, from 15dol. to 19dol. a week. There are about fifty companies engaged in this coal business, with an aggregate capital of 100,000,000dol.

EXPLOSIVE COMPOUNDS.

WHEN a powdered nitrate, whether it be a nitrate of potash, soda, baryta, or lead, is intimately mixed with coal or any substance containing carbon or hydrocarbon, such as rosin, sugar, or starch, a combustible mixture is produced, which unless enclosed or confined under strong resistance burns too slowly to form what is usually called an explosive mixture. But a slight addition of nitro-glycerine intimately mixed therewith, so as to form a thin coating over every separate grain, admits of effecting the instantaneous combustion of the whole, owing to the intense heat developed by the explosion in immediate contact with every grain of nitre which it causes to melt. Taking advantage of these circumstances, Mr. Alfred Nobel, the inventor of nitro-glycerine and dynamite, proposes to manufacture an explosive compound on this principle, his invention having been patented in England. From the nature of the mixture it will be evident that the proportions of nitre and carbon or hydrocarbonated substances, as well as nitro-glycerine, may be greatly varied with no other difference in result than an increase or decrease of explosive power; it will, therefore, be unnecessary here to do more than give the composition of mixtures which will serve as a type of the strongest and safest of such compounds. Take, for instance, sixty-eight parts of nitrate of baryta, and mix therewith twelve parts of pulverised coal—that kind which contains the greatest proportion of hydrogen being best for use. To these ingredients add twenty parts of nitro-glycerine. As a modification of this combination take seventy parts of nitrate of baryta and ten of rosin, and add thereto twenty parts of nitro-glycerine. An addition of from five to eight parts of sulphur to either of the above mixtures somewhat increases the explosive effect of the mixture, but is less safe in use. To effect the explosion of the above compounds, a tube or cap containing fulminate of mercury is affixed to the end of the fuse, the cap then being inserted into the powder. Or instead of a fuse the cap may be fired in the usual manner by electricity. In either case it is the fulminate in the cap which causes the explosion of the nitro-glycerine, which in its turn carries off the mixture of nitre and coal or analogous compound.

THE large model of Captain Moody's razed floating fort has been moored off Southend during the late severe storms. The piermaster thus writes of its perfect endurance of wind and waves:—"The model here is quite safe. We have had some terrible weather, with heavy sea. I watched it on Monday, the 13th inst., when the gale was at its highest. It rode it out with perfect safety, and with little or no strain on its cable. I wish you and some scientific gentlemen had been here to witness it." This testimony is the more welcome as it is important: the only objection really brought against this novel class of vessel having been the possibility that mooring might be difficult; an opinion which it was only possible to combat on theoretical grounds in the absence of the practical proof to be afforded by the actual mooring of a construction of considerable dimensions. Captain Moody's system will be found described and illustrated at p. 420 of our last volume.

MACHINERY FOR CUTTING VENEERS.

BY MESSRS. LYMAN AND SQUIRES.

FIG. 1.

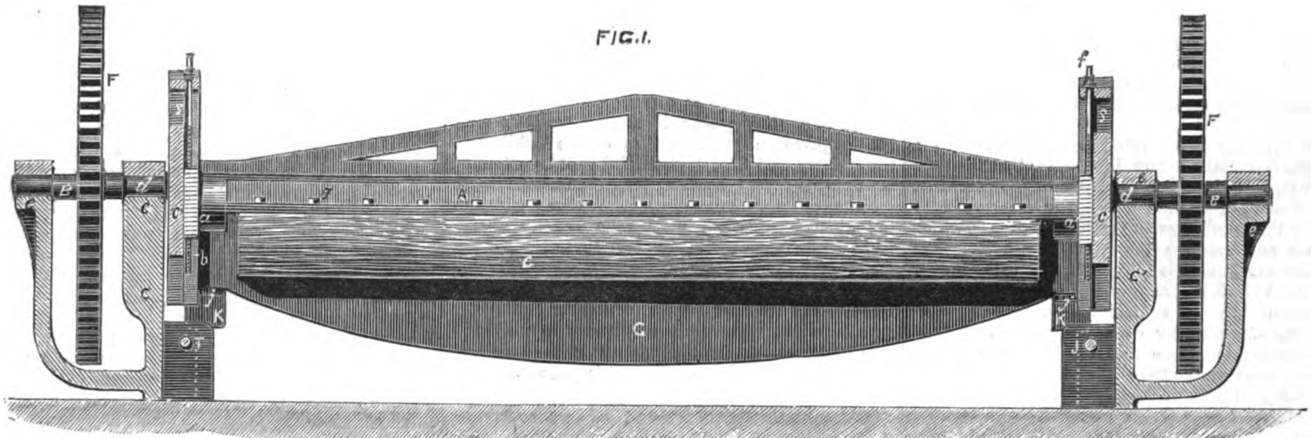


FIG. 2.

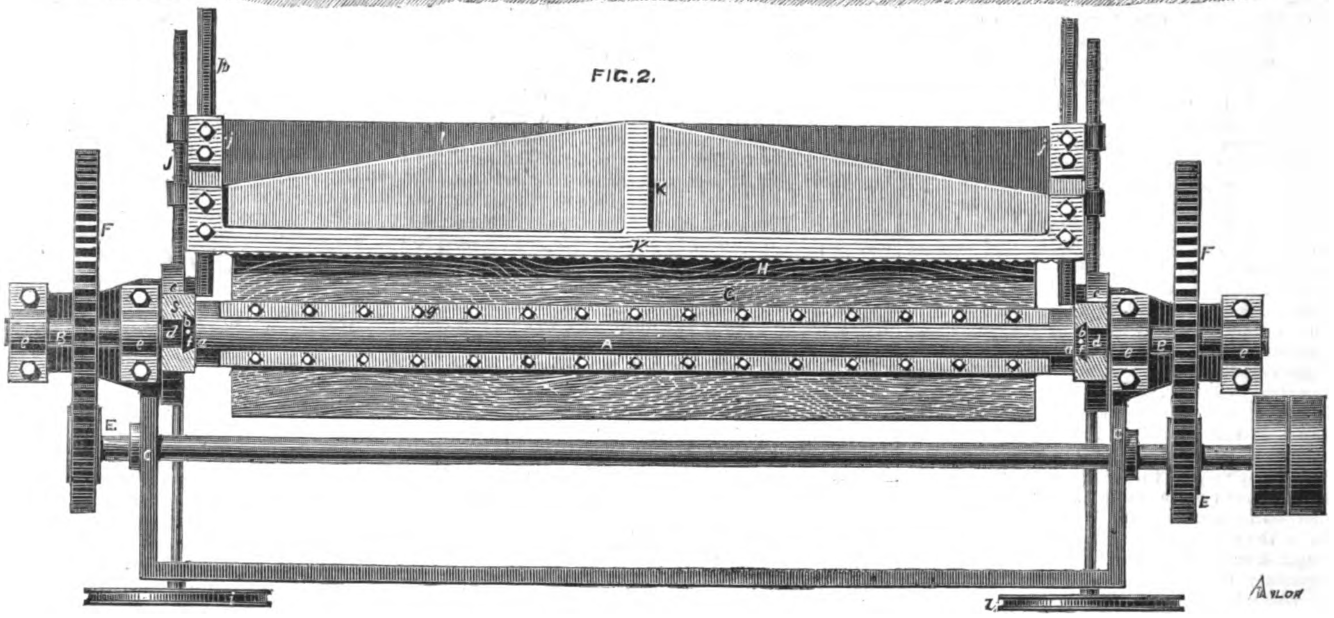

FIG. 3.

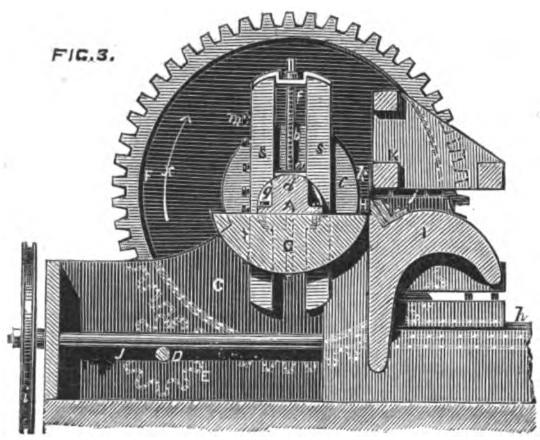

MACHINERY FOR CUTTING VENEERS.

A NOVEL construction of what is called the "stay log" of a veneer-cutting machine has been invented by Messrs. Lyman and Squires, of New York, and has been patented in England. The stay log, carrying a log, is made to revolve and present, as it rotates, the log to the action of a cutter so as to cut in curvatures corresponding to the rings of the tree. In the new construction the portion of the stay log to which the timber is bolted is rendered adjustable relatively to its journals, so that an eccentric adjustment may be given it to suit logs or log sections of different peripherical or perimetrical curvatures, and to adapt it to avoid cutting through defective portions of the log, which, in having a complete revolution given it, each cut affords ample time and opportunity to set or feed up the cutter without stopping or checking the motion of the machinery.

In the accompanying engraving fig. 1 represents a sectional longitudinal elevation of the machine, taken mainly through the centre of the revolving mechanism; fig. 2 is a plan, partly in section; and fig. 3 is a transverse section through the line *x x*, in fig. 1. The stay log represented is in its general features of the ordinary form and construction, excepting that the holding bar A is provided at its extremities with dovetail pieces *a a*, which are fitted to slide vertically within grooves *b b*, formed by ways *s s*, fast to flanges *c c* on the shoulders of journals *d d* of shafts B B, that rotate in bearings *e e* of the main frame C. These end pieces *a a* are secured within the grooves *b b* by means of set screws *f f*, locking or set screws *m m* serving to steady and hold the slides when adjusted. D is a shaft passing lengthwise of the machine, and to which the driving power is applied, and by which the same is imparted to the holding bar A by means of pinions E E, secured upon the ends of the shaft and gearing with cog wheels F F upon the shafts B B, that drive or rotate the holding bar A. By this application of power to both ends of the holding bar torsion of the latter is prevented.

In the operation of the machine the timber or log is first divided longitudinally into sections, and the flat surface of a section G of the divided log is secured by screw bolts *g g* to the flat surface of the holding bar A, substantially as in stay logs of ordinary construction. The veneer is cut as the log rotates in the direction of the arrow *x*, fig. 3, by the contact and passage of the log over a cutter H, carried by a stout metal frame I, which is adjustable horizontally on ways *h h* by means of screw shafts J J, turned by wheels or pulleys *i i*, to adjust the knife relatively to the log, and to give it feed for cutting a succession of veneers from the latter as it is rotated. K is a stout metal frame, seated and made vertically adjustable by means of screws *j j* on the knife frame or holder I, and carrying in front at its lower end a plate *k* for guiding the log to and steadying it during its cut. After the log has been secured to the holding bar A and the knife set or fed to effect a cut the section is adjusted relatively to the journals *d d* by the sliding of the end pieces *a a* inwardly or outwardly within the grooves *b b* to or from the axial centre of the journals, so that the outer or convex surface of the log may revolve at a uniform distance from the cutting edge.

By this radial adjustment of the holding bar to the journals *d d* the cuts may be made with grain or in conformity with the rings of the tree when working timber cut from trees of different size or girth, and consequently different curvatures on the side or surface exposed to the cut. By means of this adjustment of the holding bar any desired deviation from such lines of cut may be made to avoid defects or flaws in the wood. In thus adjusting the log section relatively to the journals *d d*, much timber is saved which otherwise would be lost. When the log section has been rotated past the knife to take off a veneer from its peripherical surface the revolving motion of the timber and its holding bar is continued in the same direction to cut a second veneer, and so on in succession, the interval which takes place between the succeeding rotations of the timber past the knife affording ample opportunity to feed up the knife when the log section is clear of the latter to give to the knife the proper set to effect a succeeding cut.

MACHINERY FOR STAMPING SHEET METAL.

BY MR. W. D. GRIMSHAW.

FIG. 2.

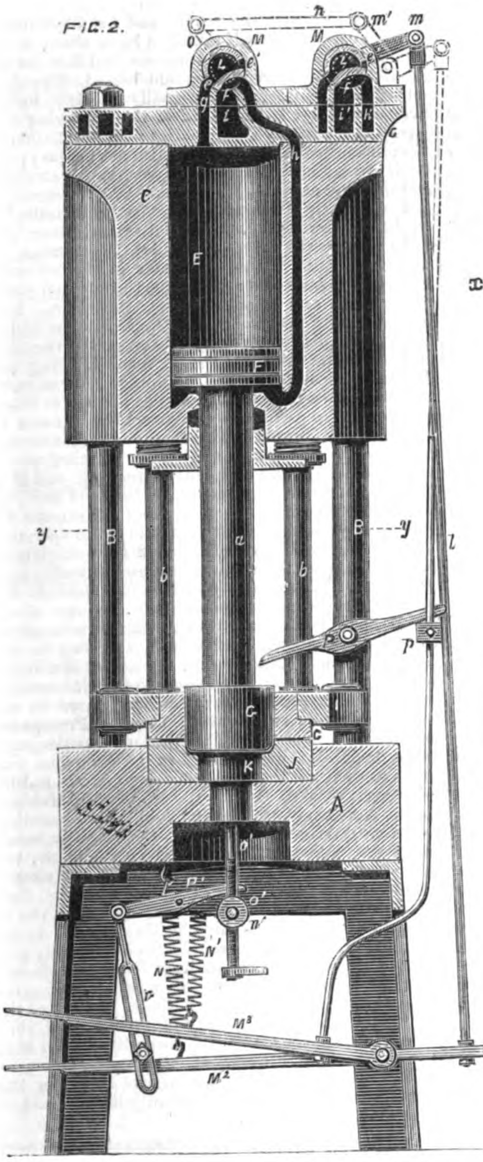

FIG. 1.

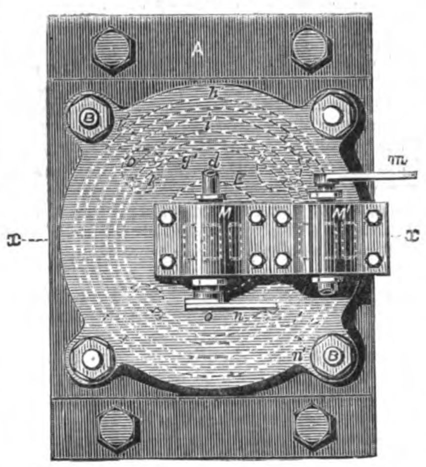

FIG. 4.

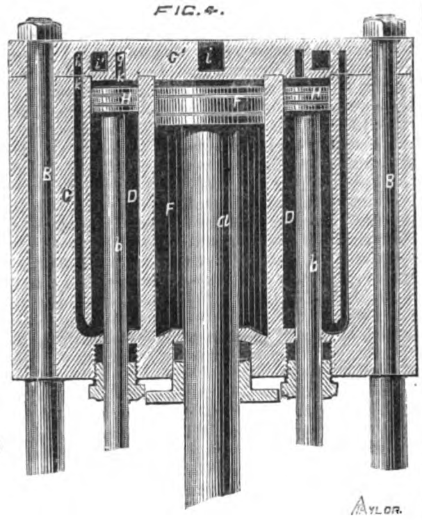

FIG. 3.

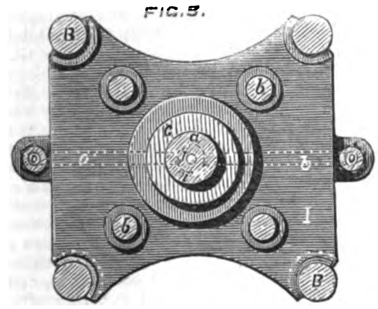

MACHINERY FOR STAMPING SHEET METAL.

THE object of the invention we herewith illustrate is the production of various kinds of sunken sheet metal work either heavy or light in a more perfect manner than has heretofore been done. The sheet metal plate is placed on and over the die, and a holding plate or block (carried by a series of pistons) is brought down to bear on the margin of the plate outside of and around the hollow of the die. The plate thus held is then subjected to the action of a stamp, operated by a main piston arranged to press the sheet metal plate into the hollow of the die. The pistons may be operated either by steam, air, or water, so that the whole apparatus forms what may be termed a steam, pneumatic, or hydraulic cylinder engine press. It will suffice here to describe the press as being worked by water under a head, and in this connection it is preferred to operate the pistons by water forced into a reservoir or reservoirs, having a compressed air space above the water therein for the purpose of giving an elastic action to the pistons. The invention is due to Mr. W. D. Grimshaw, of Newark, New Jersey, U.S., and two others, and has been patented in England.

In our engraving, fig. 1 is a plan of a machine constructed in accordance with these improvements; fig. 2 is a vertical central section taken in the line x x in fig. 1; fig. 3 is a sectional plan taken in the line y y in fig. 2, and fig. 4 is a vertical section in part through the line z z in fig. 1. A is a base block resting upon a suitable foundation, and B B are pillars serving to carry the upper castings C C ^{1}, in the lower one C of which are arranged a series of vertical cylinders D D, situated at an equal distance from each other. They surround a main cylinder E, which carries the stamp operating piston F, the rod a of which works through the lower end of the cylinder, and has the stamp G secured to it. The outside cylinders D have pistons H in them, the rods b of which project downwards, and are connected at their lower ends to a block I made up in part of a central bush c through which the stamp G works. This holding block I is guided as it is worked up or down by the pillars B B. In the centre of the base block A is a die J of the required form for the work.

The sheet metal plate to be worked into a sunken form is placed over the die J, and the pistons H are brought down so as to cause the holding block I or its bush c to bear on and hold the sheet metal plate around the hollow of the die J. The piston F then descends and carries down with it the stamp G, which pressing the sheet metal into the die gives the required form and finish to the work. After this and during the ascent of the stamp G and holding block I, a work clearer or raiser K has an upward stroke given it through the die to remove the work out of the latter.

The water to operate the pistons is drawn from a reservoir arranged to give the necessary head, and is introduced by pipes d d, and connected at their smaller ends to the interior of slightly tapering cylindrical valves L L ^{1} oscillating in chambers M M ^{1}. Each of these valves is constructed with side ports e e^1 and an exhaust passage f. The port e of the valve L serves to convey the water by a passage g to the upper portion of the cylinder E, while the port e^1 of the valve conducts the water by a passage h to the lower portion of the cylinder or beneath the piston F, accordingly as the port e or e^1 is brought in line with its respective passage g or h. The exhaust passage f of the valve L establishes communication alternately between the passages g h and an outlet or escape passage i. The ports e e^1 of the valve L ^{1} as the latter is oscillated similarly serve to conduct the water under pressure to passages g^1 h^1, while the exhaust passage f of the valve establishes communication alternately between the passages g^1 h^1, and an outlet or escape passage i^1, which is annular to serve as a general exhaust passage of the several cylinders D. The passages g^1 h^1 are also of similar character, and communicate respectively with the opposite ends of the cylinders D by openings and branches k and k^1.

To bring down the pistons and work the holding block I, the operator applies his foot to a treadle M ^{2}, which through a rod l and arm or lever m adjusts the valve L ^{1} so as to admit water to the passage g^1 to act upon the tops of the pistons H, at the same time opening the passage h^1, which connects with the bottoms of the cylinders D to the exhaust. This holds the sheet metal plate firmly down on the die J while the operator applies his other foot to a treadle M ^{3}, that through a rod l^1, bell crank m^1, rod n, and arm o operates the valve L to cause it to admit water by the passage g to the top of the cylinder E, and to open the cylinder from below by the passage h to the exhaust, which causes the piston F to descend and the stamp G (connected therewith) to press the metal plate into the die, and so form the work, as represented in fig. 2. The operator then releases his feet from pressure on the treadles, when springs N N ^{1} operate upon the latter to reverse the position of the valves L L ^{1}, so as to exhaust from above the upper faces of the pistons F and H and admit water under pressure to act upon their under sides, for the purpose of raising the holding block I and stamp G. Connected with the holding block I by side bars O and a cross rod O ^{1} and (made adjustable through a swell n^1 on the latter) is a screw rod o^1, which, as the holding block rises, serves to lift the work clearer or raiser K, that works through the die and removes the work from the latter.

To prevent waste of water by lift of the several pistons to an extent greater than is necessary for the clearance of the work from the press, and to give the pistons a variable lift (in an automatic manner) to suit work of different depths and thicknesses, the valve or treadle motions have connected with them adjustable devices, which serve to close the valves so soon as the stamp and holding block have reached their requisite elevations. Thus the stamp G when sufficiently raised is caused to act upon a trip lever P, which presses down upon a sleeve p (made adjustable on the rod l^1 to suit different lengths of stroke to the stamp) and thereby to work the valve L so as to close it, while the cross rod O ^{1} (in or by the ascent of the holding block I) similarly operates on a trip lever P ^{1} to depress the treadle M ^{2} to an extent sufficient to close the valve L ^{1}, the trip lever being connected in an adjustable manner by a slotted link r with treadle to provide for variation in the required lift of the holding block.

FLOATING TELEGRAPH STATIONS.

THERE is an instance how real merit will outlive unfavourable opinion in the scheme of floating telegraph stations. A few years ago a fierce paper war was waged on this subject, and the majority of sailors and engineers took the trouble to pronounce the scheme "impossible" and "mad." Gradually, however, one by one, some sailors and engineers, beginning perhaps both to understand the subject, came round, a few as advocates, more as well-wishers. But the public has never from the first suggestion to the last backed the hopes of the

various promoters of the scheme with substantial aid, and now we find it likely to obtain a fair trial only by the broad-minded spirit of a company already celebrated for its achievements in telegraphy.

The first scheme of a floating telegraph station which assumed a developed form was that of Captain Herbert, of the Trinity House. The ship suggested to be employed by him was a circular pontoon, to be moored from its centre of gravity, and in so far as experiments went, it gave promise of much that its inventor professed of it. It was proposed to anchor a row of light-ships on each side of the fairway of shipping, like the lamp-posts on each side of a street. Most, if not all the ships, were to have been connected by telegraph wires with the coast, and the whole would have formed, in our opinion, a most valuable, although obviously most expensive, aid to the navigation of the channels. A proposition of such ambitious pretensions was not likely to be looked upon with favour by the Trinity Board; partly because it was, in some sense, a mild reproach to that board for its own inefficient system of light-ships. Captain Herbert was an employé of that board, and such an implied reproach might have been under circumstances calculated perhaps to arouse personal prejudice rather than support. Anyhow, his scheme found no favour in that quarter, but his form of pontoon was adopted for some buoys which were placed, and gave, we believe, evidence of the correctness of the principles upon which they were constructed. The attempt made to carry out this light-ship scheme by means of a limited liability company also failed, although supported by the authority of such names as that of Mr. C. E. Varley as electrician, and Mr. E. A. Cowper as engineer.

The subject of floating light-ship stations was next taken up warmly by Mr. M. Beale, whose merit in the affair consisted in the collection of a great deal of valuable information. Mr. Beale succeeded in pushing the subject so far as to issue a prospectus of a company, with a proposed capital of £100,000, to establish telegraph light-ships off Scilly and Cape Race. The public, however, did not respond favourably, although asked in the names of a most respectable board of directors supported by the engineering authority of Mr. H. C. Forde and Mr. Jenkin. The details of the system were very carefully worked out, and a good suggestion was then, we believe, for the first time brought forward to institute a service of steam tenders to render assistance to derelict vessels and to sell stores. With the exception of Mr. Sabine's propositions to connect the Trinity House lightships with the coastguard stations by telegraph cables, and a few suggestions in the meantime from various other sources, all which came to nothing, the subject had dropped out of sight until, a short time ago, it was taken up by the Telegraph Construction and Maintenance Company. This company have, with a just appreciation of the important results which may arise from the systematic establishment of advanced telegraph stations of this nature, determined to anchor their steamship "Investigator" for a few months in the chops of the Channel, and to connect her by a telegraph cable with the shore. A small company with a capital of £150,000, of which £25,000 are called up, has been registered for carrying out this object, amongst the directors of which are Captain Sherard Osborn, the able chairman of the Construction Company, and Mr. Bevan, of the firm of Barclay and Bevan.

After the expiration of a few months the company will be in a position to judge whether the system advocated by so many authorities affords really the advantage and profit expected from it. If so, this first experiment will form the nucleus of considerable extensions; if not, the company will pick up their cable and send the "Investigator" again upon her old work of cable laying. In having thus taken the scheme in hand, the Construction Company have done what no other company is so well in a position to do, and will by this time next year either have definitely proved the soundness of the arguments brought forward in support of the scheme, or have silenced them for ever. Without some such timely aid this scheme would have slumbered on, for the public would never have subscribed capital enough to pay for the advertisements. This is amply proved by the fact that out of the £25,000 required for this experiment, the public proper, up to the day in which the share list was closed, had subscribed only £90; the shares having been taken up by capitalists whose interest had been enlisted in the scheme from previous knowledge or personal representation. The capital will be devoted thus—£1,200 to the general manager for "past expenses," his future expenses, the cost of steam tug and moorings, the hire of cable and light-ship, and the salaries and wages of the staff.—The "Engineer."

A great fire has occurred at Bordeaux from the ignition of a barge load of petroleum. Sixteen ships have been destroyed, but fortunately only one life is reported to have been lost.

EQUILIBRIUM STEAM FIRE ENGINE FOR HAMBURG.

In May last, the Fire Deputation of Hamburg issued notices for designs and tenders for a steam fire engine for service in that city. After a careful investigation of the various designs sent in by English and Continental manufacturers, that of Messrs. Shand, Mason, and Co. was selected. It has now been fully tested by the authorities in Hamburg, as will be seen by the following extract, translated from the "Hamburgeschen Correspondent" of September 24:—"The new fire engine manufactured by Shand, Mason, and Co., of London, for the Hamburg Fire Commissioners, was, for the first time, officially tried yesterday in presence of the members of the deputation. In the space of about seven minutes from lighting the fire, there was steam pressure sufficient to work the engine, but, in consequence of the prevailing strong wind, the height could not be ascertained. After this the engine was taken to a more sheltered place on the harbour where the trial was continued with the greatest success. The Fire Deputation expressed their entire satisfaction with the results obtained. At the Industrial Exhibition now being held at Altona, near Hamburg, Shand, Mason, and Co. were awarded the gold medal for the best and most efficient steam fire engine, that being the highest honour the jury had it in their power to bestow."

AMMONIA POWDER.

The following account of a new explosive material appears in the "Kolnische Zeitung," May 19, which gives the "Militar-Wochen-blatt" as its authority:—It is now some time since the proprietors of the Nora-Gyttorp Powder Mills obtained a patent in Sweden for the discovery of the so-called "ammonia powder," a substance which has hitherto been only employed in a few mining districts, but which otherwise seems wholly unknown. We are, therefore, fully justified in calling attention to the particular properties of this new explosive material. During the short time that it has been employed, it has won the approval not only of the proprietors of mines, but also of the working miners themselves. Its explosive force may be compared to that of nitro-glycerine, and, consequently, far surpasses that of dynamite. It cannot be exploded by a flame or by sparks, and the explosion is affected by a heavy blow from a hammer. Blast holes loaded with this powder are exploded by means of a powerful cap, or, better, by means of a cartridge containing common powder, for this forms a more reliable exploder. Miners who have been obliged to give up the use of nitro-glycerine, on account of the danger connected with this powerful explosive agent, have a most satisfactory substitute in the ammonia powder, as the danger of using it is so small that it surpasses in safety every other blasting material. One of the useful and important properties of this new powder is, that it does not require heating in cold weather, whilst nitro-glycerine and dynamite must first of all be warmed, and this has been the cause of many accidents. The price of the ammonia powder is the same as that of dynamite. The same paper further adds:—According to information we have received, ammonia powder was discovered by the chemist Norrbin. The German "Building News" contains extracts from a report of the Prussian architect Steenke, who makes the following remarks upon the safety of ammonia powder:—Experiments were made by fastening a lamp to a pendulum, which was caused to oscillate; gunpowder, gun-cotton, nitro-glycerine, and dynamite all took fire as the flame passed over them, but the ammonia powder did not begin to burn till it had been touched by the flame twenty times. In making experiments upon the force of the blow required to explode it, it was found that, with the apparatus employed, where the fall of a weight from 4ft. to 5ft. would explode gunpowder, nitro-glycerine only required 1¼ft. to 2ft., dynamite 2¼ft. to 8ft. fall, whilst a fall of from 12ft. to 15ft. was necessary to cause the explosion of the ammonia powder.

WHITWORTH SCHOLARSHIPS.—THE PRACTICAL EXAMINATION.

The examinations, on the results of which the first Whitworth Scholarships of £100 a year have just been awarded, deserve more than ordinary notice, as they are the first which have combined theoretical knowledge with the practical use of tools and skill in handicrafts. It will be remembered that when Mr. Whitworth offered to found a certain number of scholarships, by handing over £100,000 to trustees for that purpose, he desired that these scholarships should be awarded, in open competition, to young men, subjects of the United Kingdom, who showed the greatest amount of intelligence and proficiency in the theory and practice of mechanics and its cognate sciences. According to the regulations which were afterwards drawn up by Mr. Whitworth, it was settled that the competition should be decided by two examinations, one of which should test in a high degree the theoretical knowledge of the candidates, and the other their practical knowledge in mechanical handicrafts and the use of mechanical tools.

The endowment being vested in the Lord President of the Council, the carrying out of the founder's scheme rested with the Science and Art Department, Mr. Whitworth himself taking a large share in the arrangements required. It was decided that the two examinations referred to should be:—1. The theoretical examination, held annually in May, by the Science and Art Department, in the following subjects:—Elementary mathematics; higher mathematics; theoretical mechanics; applied mechanics; practical, plane, and solid geometry; machine construction and drawing; acoustics, light, and heat; magnetism and electricity; inorganic chemistry; metallurgy; freehand drawing. 2. A special examination, also to be held by the Science and Art Department, by which the skill of the candidates in the following tools was to be tested:—The axe, the saw and plane, the hammer and chisel, the file, the forge. And, further, their proficiency in the following under-mentioned handicrafts was to form part of the competition, viz.:—Smith's work, turning, filing and fitting, pattern-making and moulding. It was moreover laid down that none should be eligible to obtain a scholarship, under any circumstances, unless he should have passed satisfactorily in elementary mathematics, theoretical mechanics, practical, plane, and solid geometry, and freehand drawing, and in at least one of the before-mentioned classes of tools.

In order to assist in commencing his scheme for scholarships, which could only come into operation by degrees, Mr. Whitworth created sixty exhibitions or premiums, of the value of £25 each, tenable until April last. These were placed at the absolute disposal of the governing bodies of the various educational institutions and towns. Eight were given to Owen's College, Manchester, and two to the Grammar School, Manchester, the seat of Mr. Whitworth's workshops; three each to the Universities of Oxford, Cambridge, and London; three to the Society of Arts; two to the College of Preceptors, and one each to about thirty other universities, colleges, or public schools; and in addition one was given to each of the following towns, viz.:—Birmingham, Bristol, Swansea, and Cardiff, Halifax, Leeds, Northampton, and Sheffield, for presentation to the most deserving artisans. Each locality nominated the student it considered most eligible, the only conditions being that he should not exceed twenty-five years of age, and that all who were thus aided to qualify themselves were to undertake to compete for the scholarships in May, 1869. At the examination in May, 106 candidates accordingly presented themselves as competitors for these scholarships, including about fifty-five who held the exhibitions above referred to. Of these just over half, or fifty-four, failed to qualify in the essential subjects, and were consequently disqualified from further competition. Some of the successful ones showed great proficiency, the highest obtaining 122 marks, a standard which it is hardly likely could at any time be much excelled.

The details of the practical examination had next to be arranged, and, owing to the novelty and somewhat difficult nature of the scheme, it was not till September 15 that the work was completed, and the awards made known, which were published in the Mechanics' Magazine for September 17. The gentlemen appointed to the task of acting as examiners were Colonel Rich, R.E.; Mr. Marshall, secretary to the Mechanical Engineers; and Mr. Manby, hon. secretary to the Civil Engineers. As the latter gentleman was prevented from acting, his place was supplied by Mr. Hoyle, secretary to Mr. Whitworth. In order to economise the cost of the candidates' travelling as much as possible, it was found expedient to hold two examinations, one in London, and the other at Mr. Whitworth's works, in Manchester. By this arrangement, those who resided in the neighbourhood of London, and who did not wish to be examined in handicrafts, were not required to go to Manchester; and those who completely failed in the more elementary examinations were likewise saved the journey to that town, where alone there was convenient accommodation accessible for testing the various handicrafts.

For the purpose of holding the examination in the use of tools for the London candidates, Messrs. George Smith, Taylor, and Co., the Government contractors, lent their workshops at Pimlico, and these competitors, numbering twenty-one, commenced their work at 9 a.m. on August 30. Each candidate might take up one or more of the sets of tools, and two hours were allowed for each set; to those few who attempted all five sets eight hours were given to complete their work. The candidates from the neighbourhood of Manchester presented themselves on September 7, at the works of Messrs. Whitworth and Co.; they numbered twenty-five, so that altogether forty-six were in this part of the competition. The examination at both places was the same, and consisted of the programme which appears at page 138 of our present volume. As before mentioned, two hours were allowed for each

OVERHEATING OF FURNACE CROWNS AND BOILER PLATES.

BY MR. L. E. FLETCHER.

FIG. 3.

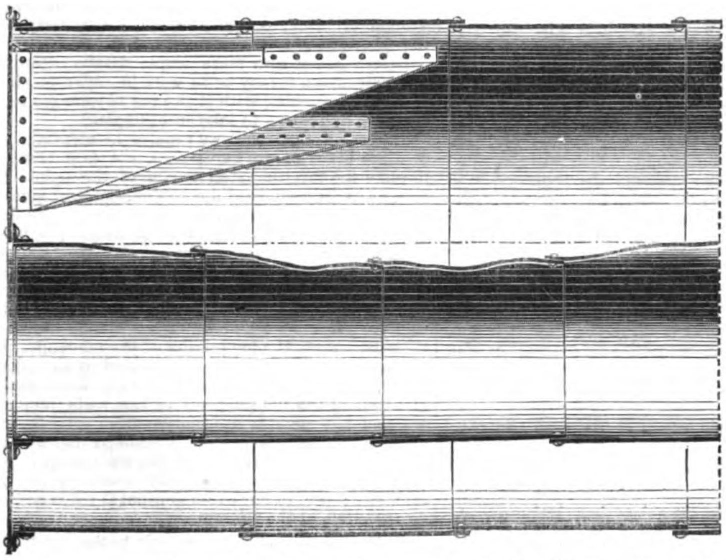

FIG. 4.

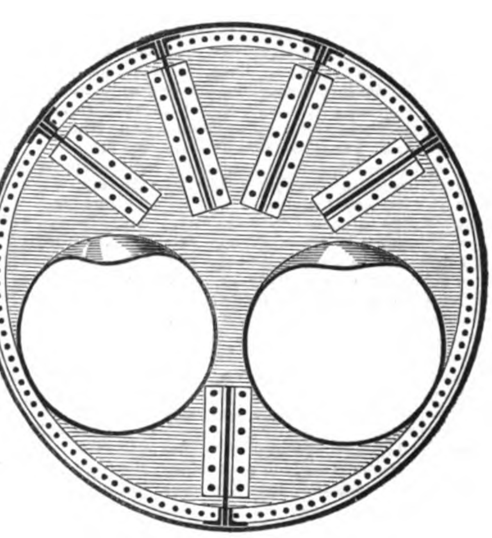


set of tools, though it was stated that, if the work were completed before that time, the time actually spent in the operation would be recorded, and taken into consideration in awarding credit. The proportion of the members who selected the different classes of tools will be seen from the following table, which appears in the "Society of Arts' Journal":—

	London.	Manchester.	Total.
The axe	9	10	19
The saw and plane	18	21	39
The hammer and chisel	19	20	39
The file	19	22	41
The forge	13	10	23
Total individuals examined	21	25	46

Such, then, was the examination in the use of tools, and it was open, to all who wished to gain additional marks in the competition, to be examined in one or more handicrafts. Those who put down their names for this examination had to present themselves at the workshops of Messrs. Whitworth and Co., on Thursday and Friday, September 8 and 9, and the nature of the tests applied to ascertain their proficiency and skill was as follows:—

Turning.—All taking up this handicraft were required to bore out a bevil-wheel to 1¼in. in the hole, using two drills and a finishing-bit, which were supplied. Also to turn up a piece of round iron supplied to them, to serve as a mandrel, to force on the wheel with the mandrel press, and turn it up on the back and face and tops of the teeth, and to scrape it up clean and smooth like the pattern.

Fitting.—All taking up this handicraft were required to key a boss upon the short shaft, cutting a key-way 7-16in. square, and letting the key half into the shaft, and half into the boss, to file up the key and fit it well in, and to let the end of the shaft project 1in. through the boss to support the head of the key.

Pattern-making.—All taking up this handicraft were required to make a pattern of a short piece of a girder, from a sketch and material given to them. The pattern was to be ready for the foundry, including the core-box for the two bolt holes in the flange of the girder.

Smith's-work.—No paper was set in this, as it was not required.

Four hours were allowed for each of these practical examination papers, and every candidate was allowed to attempt one or more, as he thought proper. Pattern-makers were required to bring the necessary tools with them, but other candidates had to work with the tools supplied to them, and were not allowed any others.

As regards the quality of the work performed at these examinations, and the amount of skill displayed, it is not possible to say anything at present, as no report has been published by the examiners of the Science and Art Department on the subject. It is, however, certain, from the lists of results issued to the candidates, that the practical examination very much altered the relative position which the candidates had attained in the theoretical. For instance, Mr. W. H. Greenwood, who stands first in the combined examination, was but eleventh in the theoretical portion; also Mr. Elgood has jumped from thirteenth to the fourth place, and Mr. J. N. Brittle from the thirty-eighth to the sixth, whereas those who stood fifth, sixth, eighth, and ninth in the theoretical, have failed to secure a scholarship at all.

In Mr. Whitworth's original scheme, he stated that he wished the number of marks obtainable in the theoretical subjects and those obtainable by the most skilled workman should be about equal; and also that he intended, by requiring a practical acquaintance with a few simple tools to be a *sine qua non*, to render the competition accessible on fairly equal terms to the student who combines some practice with his theory, and to the artisan who combines some theoretical knowledge with perfection of workmanship. Taking the experience of this year, there can be no doubt that any student wishing to compete on a future occasion would do well to pay particular attention to this practical branch of the work, which, it has been shown, will tell so decidedly in the competition; and also any artisan, having the same object, should study carefully the essential theoretical subjects which have thrown out so many. To encourage the attainment of high theoretical knowledge, combined with a practical and skilful acquaintance with the means employed in mechanics, was the chief object that Mr. Whitworth had in view when he established and so munificently endowed these scholarships, and, as a first trial, the result seems to be eminently successful, and cannot fail in a few years, when it becomes more widely known, and when the competition becomes more keen, to have a most important bearing on the mechanical industry and well-being of the country. It will, undoubtedly, in the words of the letter to Mr. Disraeli, in which Mr. Whitworth presented his endowment, "be the means of bringing science and than industry into closer relation with each other they are at present in this country."

OVERHEATING OF FURNACE CROWNS AND OTHER BOILER PLATES WHEN COVERED WITH WATER.

BY MR. L. E. FLETCHER.

THE fourth case of injury to furnace crowns through the use of a feed-water forming a fine floury deposit, came under my notice in August, 1867, and occurred in the neighbourhood of Lancaster to a range of three Lancashire boilers, measuring about 28ft. in length, 7ft. in the diameter of the shell, and 2ft. 7½in. in that of the furnace tubes, which were strengthened with T-iron hoops at each of the ring seams of rivets, while the blowing-off pressure was about 60lb. per square inch. In this case, though the feed water was drawn from a neighbouring stream, which was perfectly clear to the eye, these boilers were found to give repeated trouble at the furnace crowns, the plates bulging down, and the ring seams straining and leaking. The fault had erroneously been attributed to the construction of the boilers, in consequence of which the encircling hoops had been removed and the furnaces renewed with ordinary lap-riveted plates. This alteration was clearly in the wrong direction, and the plates soon bulged and the seams soon leaked again as badly as ever. The accompanying cuts, figs. 3 and 4, will show the nature of the distortion of the furnace crowns in this case.

At this juncture, I was requested to make an examination, and, on getting inside one of the boilers, found that it contained a considerable quantity of light floury deposit very similar to that met with on previous occasions, and already described, while, in addition, the feed-water was heated by the exhaust steam from the engines, and thus charged with grease. Though a surface blow-out apparatus was fixed to these boilers, it was quite neglected, the connection between the internal collecting trough and the scum tap being broken off, so that it was rendered useless, while the boilers altogether had been very carelessly looked after. These facts were faithfully reported to the manager of the works, coupled with the recommendation that the practice of heating the feed-water by the injection of the exhaust steam should be at once discontinued. But this view of the case by no means proved acceptable. The manager was resolved to have the boilers condemned, and not their treatment or that of the feed-water. The following analysis, however, of the feed water and sediment formed by it shows how similar they were in character to the previous cases referred to:—

SEDIMENT.

Carbonate of lime	84·210
Sulphate of lime	1·447
Carbonate of magnesia	8·991
Iron-peroxide, alumina	1·811
Silica sand	1·441
Moisture and volatile matter	7·100
	100·000

N.B.—The volatile matter seemed to be of an oleaginous nature and could not well be estimated.

WATER.

	Grains per gallon.
Carbonate of lime	11·228
Sulphate of lime	8·840
Carbonate of magnesia	2·224
Chloride of sodium	2·460
Silica	0·550

Total residue, 20·440
Hardness before boiling, 13·5de
" after " 4·5deg.

N.B.—The water was clear, slightly acid, and contained but a trace of iron.

Looking at the above analysis, there can be no question that the character of the feed water and the introduction of grease, coupled with the practice of allowing the sediment to accumulate in large quantities in the boilers, was the cause of the injury to the furnace crowns, as in the cases previously referred to, while it may be added in confirmation that, after examining these boilers, I was informed that one, if not more, of the fusible plugs had been blown out though covered with water at the time, which is a clear evidence that overheating had taken place. Trying, however, as the feed-water was in this instance, the injury to the furnace crowns would have been materially reduced, and probably avoided altogether, had the apparatus for blowing out from the surface of the water been kept in good order and regularly used.

It may also be stated that, at the time of my visit, I strongly urged that the boilers should be gently fired, since, under the circumstances, hard firing might bring the furnace crowns down in two hours. I had but just returned to Manchester when the manager wrote me that another of the boilers had failed at the furnace crowns, and the works, in consequence, were at a standstill. Hard firing is an important element in these cases of injury to furnace crowns with waters containing this fine floury deposit.

The fifth case which may be referred to occurred in Sunderland to a boiler of the patent double furnace conical water tube class, and my attention was called to it in January, 1868. This boiler had been found to fail repeatedly at the plates and seams of rivets in the furnaces, in consequence of which frequent repairs had been had recourse to, and, supposing that the injury to the boiler was due to expansion of the parts and to too much rigidity, a hoop of bridge rail or horseshoe section had been worked out of Low Moor iron, and introduced at one of the ring seams of rivets in each of the furnaces in order to give elasticity. This, however, proved of no avail, the furnaces again gave trouble and bulged inwards, when some strong stays, lashing the furnaces to the shell, were put in, somewhat as in the case of No. 2, and as illustrated in figs. 1 and 2.

At this juncture the owner of the boiler, who was a corresponding member of this Association, saw me with regard to it, and from his sketch of the shape in which the furnaces had given way, the case appeared very similar to those already mentioned, while it turned out on inquiry that the feed water contained a good deal of carbonate of lime, and that it was heated by the exhaust steam, and thus received the engine sewage. I laid the facts of the previous cases before the owner of the boiler, and on his return he had the feed water changed, when the bulging of the furnace crowns ceased, while it may be added, that he found on reference that the difficulty with the furnace crowns had commenced with the use of the feed water in question, so that this afforded a double proof of the cause of the injury.

The sixth case which may be mentioned, and to which my attention was first drawn about March, 1868, gave as much perplexity as any one of them. It occurred to an ordinary Lancashire boiler in the neighbourhood of Manchester, while the feed water, which was drawn from a well sunk on the premises, was heated by the exhaust steam from the engine. The boiler measured about 24ft. in length, 6ft. 9in. in the diameter of the shell, and 2ft. 3in. in the furnace tubes, while it was worked at a pressure of about 55lb. on the square inch. This boiler had been originally constructed for experimental purposes, in consequence of which some steam pipes from 10in. to 12in. in diameter, were carried through it from one end to the other, which thus served as longitudinal stays to the end plates. As these complicated the boiler, they were removed, and gusset stays substituted for them.

Shortly after this, the furnace crowns were observed to leak. Whether this had commenced before the removal of the pipe stays just referred to or not is difficult to ascertain; at all events the owner attributed the difficulty with the furnace crowns to the removal of these pipes and the introduction of gussets in their place. This, clearly, however, had nothing to do with it, though it was not very apparent what was the real cause. After repeated minor repairs, however, were found useless, the furnace tubes were taken out altogether, the front half of them entirely renewed and strengthened at two of the ring seams of rivets with T-iron hoops, while the front end plate of the boiler was also renewed. The manner in which the repairs were executed appeared on examination to be satisfactory, nevertheless, the boiler only worked on a few weeks before leakage again commenced. A consulting engineer was then called in, who gave it as his opinion that the fault was in the workmanship, and that the overlaps had not been well drawn up. The defective seams were therefore again repaired, the old rivets cut out, the holes rimered, and fresh rivets put in.

Just at the time that the boiler was re-started, a number of practical working boiler makers had a meeting, and discussed the cause of the continued and mysterious leakage that had occurred to this boiler. One of them strongly objected to the encircling hoops, and to these he attributed all the injury, stating that he had a similar boiler under his charge which was never out of trouble, but always leaking and needing repair, while he considered such a boiler was as good as an annuity to the boiler mender, and that the man who was charged to keep the one under consideration in order would never be in want of a job. At length the meeting unanimously resolved that encircling hoops prevented any expansion of the furnaces, and that it was against all the known laws of nature for boilers constructed in this way to keep tight, and further, that within three weeks, leakage would set in again, and the works would have to be stopped for further repairs. This decision was communicated to the owner of the boiler, and surely enough, within the appointed time the boiler commenced to leak once more. At this, the owner was quite disheartened, and regretted that he had not had the boiler entirely renewed rather than repaired.

In a long conversation with the owner at this juncture, it transpired incidentally that when his men first got into the boiler after letting off the water, they found some loose fine dusty deposit within it, when it at once occurred to me that this case might be similar to the others previously recorded in this report. This had not been suspected before, since the furnace crowns were not bulged out of shape, but merely strained at the seams of vets, while, in answer to inquiries, it had been stated that the deposit altogether was of a very inconsiderable and trivial character. I therefore explained to the owner my suspicions that all the trouble he had experienced was due to the feed water, and recommended him at all events to give the boiler a trial with the Manchester town's water, instead of that drawn from the well, a recommendation, it may be added, that had already been made, as a matter of precaution, but had not been thought worthy of adoption. Though he had no faith in the remedy proposed, it was so simple that he consented to try it. The boiler was at once washed out, and the next morning started to work with the town's water. From that day the trouble was over. The boiler worked on satisfactorily for several weeks, and after being slightly caulked so as to remove the effects of the old leakages, it was perfectly sound, and though the T-iron hoops, which were decided at the meeting of boiler makers to be "opposed to all the known laws of nature," had not been removed, the boiler has worked on to this day without giving further trouble, and promises to do so for the next seven years.

The following is an analysis of the sediment, from which it will be seen that carbonate of lime is the predominating ingredient, though it does not form so large a percentage as it did in the previous cases, which it is interesting to notice in connection with the fact that in this boiler the furnace plates were not bulged, but merely strained at the seams of rivets:—

Carbonate of lime		88·960
Copper		trace
Carbonate of lead		1·790
Sesqui-oxide of iron		5·005
Alumina		4·456
Sulphate of lime		4·490
Carbonate of magnesia		1·216
Magnesia		11·847
Phosphoric acid		trace.
Chlorine		trace.
Sand and silica acid		17·977
Fat	7·375	10·742
Other organic matter	3·367	
Moisture		2·219
		98·702

N.B.—The deficiency is partly due to the given percentage of carbonate of lead being too small, and to the traces of alkalies, copper, phosphoric acid, and chlorine.

When the boiler continued to work on satisfactorily week after week, and month after month, simply by exchanging the well water for the town's water, the owner could not entertain any further doubt on the subject, and on recollecting the changes made in his works from time to time, and remembering how the well had been deepened to increase the supply, he was able to trace a clear connection between the use of the well water and the leakage of the boiler. This shortly received a striking corroboration. In the course of the long drought that occurred in the summer of 1868, the supply of the Manchester Water Works, as all in this locality will remember, began to run short, especially for engine purposes, so that for one afternoon the owner was obliged to fall back on the well water, when, though he tried the experiment for a few hours only, the boiler at once commenced to leak as before, so that he gave up the well water once more, and resolved never to return to it again. This case, though not so severe as some of the others mentioned, is perhaps the most interesting, from the great perplexity which arose with regard to it, and the conclusive manner in which it was cleared up.

ECKHOLD'S OMNIMETER.

A NEW instrument, under this title, the invention of a German engineer, M. Eckhold, has been brought out to aid in surveying operations, such as measuring the bases of triangulation, measuring distances either inclined or horizontal, measuring altitudes, and measuring angles. The omnimeter is calculated to effect an important improvement, combining in one instrument the theodolite and the level; doing away with the necessity for tedious chain measurements, and requiring in its operation no complicated calculations.

The instrument consists of the following parts:—* First, of a graduated circle, to read off each ten seconds in the measurement of horizontal angles; second, of a powerful telescope, revolving in a plane perpendicular to the graduated circle; third, of a microscope of high power, connected with the telescope and moving with it; fourth, of a highly sensitive level lying upon it; fifth, of a rule, or plane, having a fixed length (of twenty centimetres for example); sixth, of a scale fixed vertically at the extremity of the said rule, at a distance coincident with the optical axis of the microscope, which scale is divided into half millimetres (the millimetres are indicated by the numbers between 1 and 100); seventh, of a micrometrical screw movement connected with the base of the scale and giving the 2-10,000th of a millimetre of the scale, legible on the graduated circle beneath; eighth, of a second extremely sensitive level capable of being applied to the telescope and of determining, in case of need, its horizontality; further, of all the necessary screws, keys, and other matters required to secure the efficient working of the instrument.

* This description was furnished by the inventor to the Society of Arts' Journal."

As the necessary complement of the omnimeter, there is a levelling staff, not divided, but of an invariable length (as, for example, three metres), which length is defined by two white lines on a ground of black, one at the upper extremity and the other at the lower extremity of the staff.

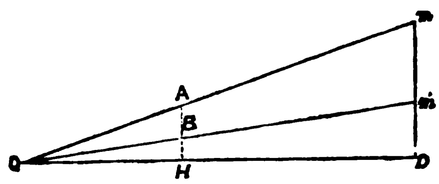
Before going into more ample details regarding the instrument, it may be as well, in order to show the way of working with it and the advantages to be obtained by its use, to take an example.

Supposing, then, that we require to ascertain the distance between any two points, the first thing is to place the levelling staff at one of the points (in this, as in all geodesical operations, the staff must of course be held in a true vertical position). We then take the omnimeter to the other point and set it up. By means of the level and its screw adjustment we place the instrument in a horizontal plane; then, directing the telescope upon the upper white line of the staff, we fix the telescope with the screw for that purpose; we read off on the scale, by means of the microscope, the inclination of the telescope. On account of the figures being magnified by the microscope, we shall be able to see only one number at a time of the 100 integrals of the scale; suppose we find the number 67 (millimetres) plus the unascertained fraction comprised between that number and the horizontal thread of the microscope. We ascertain the fraction exactly by means of the micrometer; say, in our example, that it reads as 2035 on the circle of the micrometer.

This we note down in our book to the right of the number 67 already obtained, thus	672035
We repeat this operation in every particular for the lower line of the staff, and we obtain, say	609400
The operation with the instrument is now complete, as we are in possession of the data required for calculating the distances; let us take the difference between these two quantities	62635

And divide 6000000—a constant number for all cases—by the difference we have thus obtained, and we shall have 95·79m. as the horizontal distance in question. In fact, suppose the levelling staff in position at mm', let O be the point round which the telescope revolves, AB representing the difference as found = 62635.

From the point O let us draw a horizontal line



let us produce the line AB to H, and the line mm' to D. We have then AB and mm' perpendicular to OD. In the similar triangles OAH and OmD we have the following proportions:—

$$\frac{\mathrm{OH}}{\mathrm{AB}} = \frac{\mathrm{OD}}{mm'}, \text{ then } \mathrm{OD} = \frac{\mathrm{OH} \times mm'}{\mathrm{AB}}$$

But

OH = 0·20m. (by the construction of the instrument).

mm' = 3·00m. (the invariable length of the staff).

AB = 62635 (the quantity obtained in our example by the scale).

The last quantity in fractions of the metre is 0·002635m.; if we substitute for the letters their respective values, we have—

$$\mathrm{OD} = \frac{0{\cdot}20\mathrm{m.} \times 3}{0{\cdot}0062635\mathrm{m.}} = \frac{0{\cdot}60\mathrm{m.}}{0{\cdot}0062635\mathrm{m.}} = \frac{6000000}{62635} = 95{\cdot}79\mathrm{m.}$$

In the preceding example we have supposed the staff to be placed at one point and the omnimeter at the other. This manner of operating is not, however, the only one; there are two others, one by placing the omnimeter in line with the two points, the other by fixing it at some point outside. In either case, a staff must be set up at each of the points. In the first instance the total distance is obtained directly by adding together the back and fore sights. In the second instance we obtain the distance by measuring the horizontal angle, which we read off on the great circle, and by calculating the triangle (trigonometrically) by means of the angle thus obtained and the two sides.

For the establishment of a base of triangulation, the latter mode is that which we should recommend for adoption; for, if we proceed thus by small distances from 10 to 20 metres on each side, or thereabouts, we may easily measure a base line of 1,000 metres within an approximation of 0·004m.; a result which is quite satisfactory. In fact, if for a distance of 10 metres, the scale gives us the differ-

ence 0·06m., it will give us for a distance equal to 9·99996m. the difference 0·0600002m., a quantity appreciable on the circle of the micrometer. The nature of this operation requiring extreme exactness, a staff of special construction should be employed. This staff would have the two faces similar to those already described; would be provided with supports to ensure its verticality, and, at its base, would be armed with a steel point and iron tressels. As regards the measurement of the slope or the inclined distance, the operation requires, further, the reading off of the horizontal line on the scale. We have then a new proportion:—

$$\frac{AB}{BH} = \frac{mm'}{m'D}, \text{ and } m'D = \frac{mm' \times BH}{AB}$$

Consequently,

$$Om' = \sqrt[2]{(m'D^2 + OD^2)}$$

General Observations.—The practice of the omnimeter has proved to us that in the measurement of lengths requiring extreme accuracy it is not prudent to make the points more than 200 metres apart. At that distance we are within an approximation of 0·04m.; at 500 metres, by making use of a staff 4 metres high, the approximation will be within 0·17m.; a sufficiently satisfactory result, as, by one forward and one back sight, we can determine a kilometre within 0·34m. With the chain we know, as a fact, that it is hardly possible to come nearer than within a mean of 1-700th of difference.

In levelling, the operation is identical with that we have described for the measurement of inclined distances. The quantity is given by the formula—

$$m'D = \frac{mm' \times BH}{AB}$$

that is, three (metres) multiplied by the difference of the sights, divided by the difference with the horizontal line.

The readings are obtained with the greatest precision. For distances not exceeding 100 metres, they are obtained within a fraction of a millimetre; and for greater distances (at which the instruments at present in use are inoperative) the measurement can be obtained within a millimetre. This degree of precision is attained, because:—

1. In placing the instrument, we have not to pay attention to centralising the optical axis.

2. Because the operator has always to point his telescope on the same lines of the staff, which lines denote an invariable length, viz., 3 metres.

3. Because there can be no hesitation in reading the staff as with the ordinary levelling staves, with which we have an element of guess-work not found here.

In difficult and hilly ground, levelling with the ordinary level becomes a very long and very expensive operation, because the sights are necessarily short, and because the number of them is multiplied in proportion to the rapidity of the incline. The omnimeter, as may be perceived at once from the nature of the instrument, allows of levelling points placed at great distances apart, and which make considerable angles with the horizon.

WEEKLY CHEMICAL MINERAL AND METAL REPORT.

(From J. Berger Spence & Co.'s Manchester Circular, September 30.)

Chemicals.—The chemical market during the past week has not displayed quite so much activity as in the two preceding weeks; prices, however, remain very firm and for the most part in favour of the sellers. Soda: soda ash, rather dull market, at £7 to £7 10s. for 48. Crystals inquired for at £4 5s. to £4 7s. 6d. Caustic moves off at 13s. to 13s. 6d. Nitrate of soda: being scarce is again rising and difficult to obtain under 16s. 6d. to 17s. Potash: muriates very firm, at £7 7s. 6d. to £7 10s. for 80. Saltpetre: very little doing, and prices remain the same—23s. for Bengal, and 27s. 6d. for English refined. Alum: an average business, at £7 to £7 5s. for export, and £6 5s. for home consumption. Ammonia: the demand for sulphate is still considerable, and £16 5s. to £16 10s. easily obtainable. 19 to 20 can be bought at £13. Copperas: green quoted at 52s. and 50s. for dry. Chloride of iron, 51s. per ton. Pyrites: a limited business, chiefly for Spanish, at previous quotations. Lime: sales of phosphate at 52s. for 65; bleaching powder in brisker demand at £8 10s. Disinfectants in good demand at £5 to £6 per ton for agricultural purposes.

Metals.—There is but a limited business doing in the metal market, and prices have barely maintained their previous values. An influential meeting of the North of England iron trade has taken place at Middlesborough during the past week, and the prospects of this branch of the trade were considered very encouraging. Iron: Scotch pigs are in slight demand, and the closing quotations are from 53s. to 53s. 1d. Cleveland firm, at 43s. for forge, to 48s. for No. 1. Welsh bars, £6 5s. to £6 7s. 6d; Staffordshire, £6 10s. to £7; gas tubes at 60 to 70 off list; boiler tubes, 40 to 45. Copper remains quiet, but an average business is being done, at £73 to £74 for tough ingot, and £68 to £69 for Chili slab. Tin: is rather weaker, and English is being offered under the official list. Straits £130 to £131; English £125 to £126. Lead: is in a little better demand at £19 to £19 5s. for soft English pig. Spelter: in moderate request, and English makers are all well sold forward, and look for better prices. English now selling at £20 15s. to £21; Silesian special brands, £20 5s. to £20 10s.; hard spelter for export, £16 5s. to £16 10s.

Correspondence.

SELF-RECORDING RAIN-GAUGES.

TO THE EDITOR OF THE "MECHANICS' MAGAZINE."

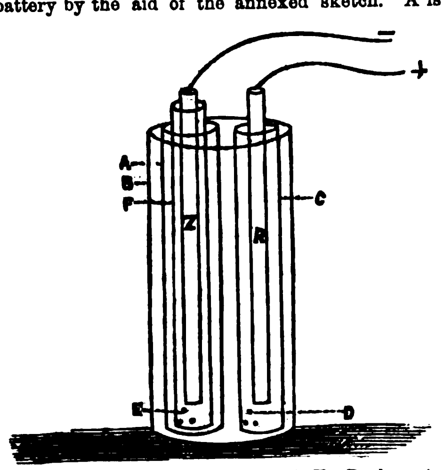
Sir,—I observe, in your last issue, a description of a rain-gauge by M. Rabache, who, in his remarks, refers to an apparatus for the same purpose by Mr. Beckley. M. Rabache finds fault with Mr. Beckley's apparatus, and as I am acquainted with the instrument to which exception is taken, I shall be glad if you will allow me to make a few remarks thereon. M. Rabache is not at all justified in putting forward his own invention (if invention it can be called) as an improvement upon Mr Beckley's. Of the latter he very justly says —"Great and minute precautions have been taken in the invention and construction of this instrument in order to render it as perfect as possible." He then goes on to urge five reasons for its imperfection, but, unfortunately, these same reasons, so far as they are sound and applicable to Beckley's, are equally so to his own instrument, which, moreover, has the additional serious defect of depending upon a reservoir of water (F in the figure). For this water, by evaporation, rapid in dry weather, will entail very erroneous indications on the register. This was, no doubt, what led Mr. Beckley to resort to mercury, very expensive, but still not appreciably affected by evaporation, so that it will not require adjustment for months. There are other particulars in which M. Rabache's instrument is much inferior to Mr. Beckley's which cannot be counterpoised by greater cheapness. I have no doubt myself that Beckley's is the best self-recording rain-gauge yet proposed, and I believe it will be adopted by the Meteorological Committee. I enclose my card.—I am, Sir, yours, &c.

September 29. A Meteorologist.

AN ECONOMICAL GALVANIC BATTERY

Sir,—In working a galvanic battery, as described in the Mechanics' Magazine, August 6, I found the copper solution within the copper cell soon became exhausted. A simple remedy is to place the zinc rod in the cell containing the platinized silver, and platinized silver in porous cell that held the zinc rod. By this arrangement the outside of copper cell receives a deposit, whilst the inside is electrically dissolved. In this new arrangement, a further improvement consists in dispensing with the porous cell holding the rod or plate of platinized silver, substituting for the latter a rod or plate of copper, which rod will receive, as well as the outside of copper cell, a deposit of copper.

I will now describe my last improved galvanic battery by the aid of the annexed sketch. A is



a porous cell containing a zinc cell F; B, the outer jar; C, a copper cell, containing a rod or plate of copper R; D, three small holes in the copper cell; E, three small holes in the zinc cell; F, a zinc cell, in which is a rod of zinc Z. The outside of the zinc cell F is coated with sealing-wax, varnish, or anything that will prevent it from being electrically dissolved. The zinc rod Z must not touch the zinc cell F; the rod of copper must not touch or be in metallic contact with the copper cell C. The porous cell contains a solution of sulphate of zinc or any other salt of zinc that will yield a reguline deposit of that metal on the inside of the zinc cell F. The outer jar holds a solution of sulphate of copper. The small holes D and E are coated with varnish to prevent them from being filled up with electro-deposit. This mode of working the zinc element is applicable to other arrangements of galvanic batteries. Other metals, when substituted for the zinc element, may be worked in the same manner. Persons familiar with electro-deposition need not be told that the deposit of zinc will vary in quality, according to the strength of the zinc solution and the relative sizes of the zinc rod and zinc cell.

I think this battery will prove to be the most economical of any yet invented. The solutions of zinc and copper will last a very long time when the various portions of the battery are nicely adjusted to each other, for each solution will be maintained at the degree of saturation commenced with if there was no loss of water by evaporation, &c.—I am, Sir, yours, &c., James Howard.

95, Cross-lane, Salford, September 24.

TO CORRESPONDENTS.

The Mechanics' Magazine is sent post-free to subscribers of £1 1s. 8d. yearly, or 10s. 10d. half-yearly payable in advance.

All literary communications should be addressed to the Editor of the Mechanics' Magazine. Letters relating to the advertising and publishing departments should be addressed to the publisher, Mr. R. Smiles, Mechanics' Magazine Office, 166, Fleet-street, London.

To insure insertion in the following number, advertisements should reach the office not later than 5 o'clock on Thursday evening.

We must absolutely decline attending to any communications unaccompanied by the name and address of the writer, not necessarily for insertion, but as a proof of good faith. Ed. M. M.

Advertisements are inserted in the Mechanics' Magazine, at the rate of 6d. per line, or 5d. per line for 13 insertions, or 4d. per line for 26 insertions. Each line consists of about 10 words. Woodcuts are charged at the same rate as type. Special arrangements made for large advertisements.

G. Jones, Liverpool.—You have no remedy against any person using your invention unless it is protected either by Letters Patent or by Registration.

Received.—H. N.—E. C.—K. and G.—W. J.—F. B.—H. P.—R. S.—W. R.—B. S. and Co.—G. E. P.—J. H.—F. F.—T. P.—J. D.—P. F.—O. G. and Co.—H. W.—O. E.—T. H.—J. G. W.—J. N.—S. and Co.—J. L.—B. and Sons—S. M. and Co.—R. N.—G. B. W.—H. S.—J. B.—F. H. and Co.—E. W. M.—C. F. T.—J. H.—R. E.

Naval, Military, and Gunnery Items.

The screw steamer "Hotspur" has sailed from Lynn for the Tyne, where she will take on board a cargo of Armstrong guns, which are intended for the Greek Government.

Dr. Hall, the Arctic explorer, arrived at New Bedford on September 26, from Repulse Bay, after an absence of five years. He discovered the skeletons of several of Sir John Franklin's party at King William's Land, and he brings numerous relics of the Franklin expedition.

Messrs. Robertson and Co. have launched a twin screw for Messrs. M'Crindall, Schaw, and Co., of Glasgow, to be employed as a towing and coasting cargo vessel at Buenos. She is being fitted by Mr. D. Rowan with a pair of direct-acting twin screw engines, on the combined high and low pressure principle.

The Secretary of State for War has authorised the issue of small-arm ammunition boxes (holding 500 rounds each), for storage of service ammunition at Aldershott Camp, on the requisition of commanding officers of regiments to the Control Office. The requisitions are to show the actual quantity of service ammunition in charge, the number of boxes, if any, on charge, and the number required.

Navigation in France presents the following results:—Out-going ships, 3,400,000 tons, of which 1,936,000 were under the French flag in 1868, against 3,450,000 tons, of which 1,538,000 were under the French flag in 1867, being a diminution of 50,000 tons outward, but with an augmentation of 57,000 tons in the case of French vessels. The foreign mercantile navies, therefore, support a loss of 107,000 tons.

The Royal Engineers' camp at Wouldham, a few miles up the river Medway from Chatham, where, during the summer months, detachments of Engineers proceed in succession from the School of Military Engineering at Brompton Barracks to go through a course of instruction in pontooning—the pontoon hard being at Cuxton, nearly opposite Wouldham—has now been broken up for the season, and a large portion of the apparatus has been conveyed from Cuxton to Brompton, to be stored there for the winter.

The demands of the Australian and Indian trades have become so extensive, and the forthcoming opening of the Suez Canal being likely to do away with the use of sailing vessels to a very considerable extent, some of the enterprising shipowners of Liverpool are combining together to substitute steam for sailing vessels. Already we hear of the formation of a large company, which has given an order for a steamer of 440ft. in length, and of light draft. Shipowners are quite alive to the changes which the successful navigation of the Suez Canal will bring about, and are building steamers suitable for the traffic by that route.

During 1868, the number of arrivals from Italian ports were 521, of a total tonnage of 48,786; the number of vessels that sailed from the port of Venice for Italian ports were 687, of 52,704 tons. The number of arrivals from foreign ports were 2,578, of 308,721 tons, and the departures 2,392, of 298,581 tons; making a total of 3,099, of 357,507 tons arrived, and 3,079, of 351,285 tons sailed. In 1866, the total number of arrivals were 2,886, of 258,435 tons, and departures 2,813, of 253,883 tons. The difference in favour of 1868 is therefore, 213, of 99,072 tons, arrivals, and 266, of 97,402 tons, departures.

The wood shipbuilding in Sunderland, says the "Newcastle Journal," was never in so stagnant a condition as at the present moment. Of 58 yards, 22 are empty and to let; 9 are occupied but have no new ships building; 7 have new ships finished, for sale, ready for market, and with the men paid off, and only 20 are in work, having ships finished or in progress, and in these there are 12 ships ready for sale, but no market for them. Seventeen wood shipbuilding yards have been converted into 10 iron or composite yards. The reason is attributed to the maintenance of the union hours and wages, which make building much dearer there than in other ports.

That time works wonders was never more apparently manifest than in the rapid strides and great improvements we have made during the last few years in ship architecture. It was but the other day when the English emigrant looked with pain into the narrow, ill-ventilated berth in which he was to be incarcerated for some three or four months in a voyage to our antipodes; but since the discovery of the precious metal in Australia our shipbuilders and owners have not been backward in their efforts to make the voyage as pleasurable as possible. The new ship "Collingrove," built by Laing, Sunderland, for the Adelaide trade, is a model of what a passenger ship should be.

An interesting ceremony took place on the Clyde on Wednesday week. By the exertions of a number of local gentlemen, the use of the war vessel "Cumberland" has been obtained from the Admiralty as an industrial training ship for the destitute and houseless boys of Glasgow and the west coast; and on Wednesday the ceremony of inaugurating the vessel took place. A large number of the subscribers to the fund for upholding the "Cumberland" were conveyed on board the vessel, which has been moored in Row Bay, nearly opposite Greenock; and after lunch had been partaken of, under the presidency of the Earl of Glasgow, speeches were made in explanation of the objects of the movement for establishing industrial training ships.

Miscellanea.

A white bear in the Zoological Garden of Florence, which had for a long time past been suffering from the itch, was destroyed three days back by a dose of 40grammes of sulphate of strychnine.

The number of visitors to the Patent Office Museum, South Kensington, for the week ending September 25, was 6,082. Total number since the opening of the Museum, free daily (May 12, 1858) 1,647,875.

The directors of the Tower Subway Company have notified that having carried their subway from the Middlesex side of the river to beyond high water mark on the Southwark side, they are prepared to receive proposals for loans upon that security.

The exports of sulphur from Sicily during the first seven months of 1868 were 142,583,914 quintals, as compared with 141,933,398 quintals during a corresponding period of the previous year. This shows an increase of 650,516 quintals in favour of the seven first months of 1868.

The number of visitors to the South Kensington Museum during the week ending September 25, 1869, was—on Monday, Tuesday, and Saturday (free), from 10 a.m. to 10 p.m., 17,029; Meyrick and other galleries, 2,681; on Wednesday, Thursday, and Friday (admission 6d.), from 10 a.m. till 6 p.m., 1,858; Meyrick and other galleries, 131; total, 21,694. Average of corresponding week in former years, 12,409. Total from opening of Museum, 8,829,761.

We are informed that baronetcies have been offered by Mr. Gladstone to Mr. Whitworth and Mr. W. Fairbairn, and that those gentlemen have accepted the honour. Our readers will rejoice with us at this recognition on the part of the Crown of the wonders achieved by these gentlemen, whom we congratulate upon the circumstance.

Mr. John Robert Seeley, Fellow of Christ's College, Cambridge, and Professor of Latin in University College, London, has been appointed to the chair of Modern History at Cambridge, vacant by the resignation of Canon Kingsley. Mr. Seeley graduated in 1857, when he was Senior Chancellor's Medallist, and bracketed senior classic with three others.

Mr. Robert Hunt estimates the annual production of the slate quarries at Delabole, near Camelford, at about 17,050 tons a year, which, at say £2 10s. a ton, would realise over £42,000 annually. The Devonshire slate quarries he estimates to produce 15,000 tons a year, value say £37,000 a year. Most of the Cornish slab is shipped either at Boscastle or Port Gavern, in Endellion.

A table which has been prepared in illustration of the production of rails in France during the last ten years presents the annexed results:—1859, 101,426 tons; 1860, 121,438 tons; 1861, 164,371; 1862, 216,175 tons; 1863, 226,948 tons; 1864, 215,983 tons; 1865, 184,131 tons; 1866, 159,061 tons; 1867, 154,351 tons; and 1868, 202,204 tons. The average price per ton in 1859 was £10 2s. per ton, while in 1868 it had fallen to £7 2s. per ton.

A considerable portion of the ruins of Kenilworth Castle having shown signs of falling, Earl Clarendon, the owner, is now repairing and strengthening the great hall, Leicester's buildings, and parts of the external walls on either side. His lordship is also restoring some of the doorways, windows, and fireplaces. In the course of the repairs excavations have been made, and underground apartments, cells, and passages revealed which had been hid for centuries.

It is asserted that one hour after the gas of London is lighted the air is deoxidised as much as if 500,000 people had been added to its population. During the combustion of oil, tallow, gas, &c., water is produced as well as carbonic acid; in cold weather we see it condensed on the windows. By the burning of gas twenty-four hours in London, more water, it is estimated, is produced than would supply an emigrant ship on her voyage from England to Australia.

Between 1852 and 1868, the Ponts Napoleon, Solferino, de l'Alma, and the Pont du Point du Jour have been built in Paris. The Ponts de Bercy, d'Austerlitz, Louis Philippe, d'Arcole, Saint Louis et Notre Dame, the Pont aux Doubles, the Petit Pont, the Pont au Change, the Pont Saint Michel, and the Pont des Invalides. The Pont Neuf has been completely restored, and the right of toll of the Pont de Grenelle has been purchased by the town.

The winter session of the South London Working Men's College, 91, Blackfriars-road, will begin to-morrow, Saturday, October 2, when a new French class will open. Among the other new classes are one in practical chemistry, under Mr. W. Rossiter, F.C.S., &c.; one in political economy, under Dr. Bithell, B.Sec.; and one in mechanics, under Mr. C. T. Mitchell, M.A. The college has also night schools for men and women and a day school of a high character under the direction of Mr. Rossiter, the honorary secretary of the college.

The following is a Turkish recipe for a cement used to fasten diamonds and other precious stones to metallic surfaces, and which is said to be capable of strongly uniting surfaces of polished steel, even when exposed to moisture. It is as follows:—Dissolve five or six bits of gum mastic, each the size of a large pea, in as much spirits of wine as will suffice to render it liquid. In another vessel, dissolve in brandy as much isinglass, previously softened in water, as will make a 2oz. phial of strong glue, adding two small bits of gum ammoniac, which must be rubbed until dissolved. Then mix the whole with heat. Keep in a phial closely stopped. When it is to be used, set the phial in boiling water.

The "Locomotive" calls the attention of steam users to the necessity of exercising greater care in the raising of safety valves. It says, it is the practice of many to lift the valve suddenly, and then let it fall, the spindle thereby receiving a violent blow; and in numerous cases we find the spindle sprung to such an extent by this practice that the valve can lift but very little, in some instances not at all. The valve should be raised carefully and let down gently; not only for the reasons above stated, but from the fact that nothing is more dangerous than the sudden shock caused by the valve being suddenly opened and shut. Valves should be frequently raised to prevent their becoming stuck, but too much care cannot be used in the operation. During the month, several cases of this evil have come to our knowledge, in one of which it was necessary to cut the spindle out after the cap had been taken off.

The "Journal Officiel" says that a chemist has discovered a method of illuminating letters whereby the names of streets, numbers of houses, and inscriptions become more distinct as darkness increases. The process is described as very simple, and consists in the application of a particular kind of liquid to the letters.

The "Minnesotian" has an account of Mr. Eames's discovery on the north shore of Lake Superior, at the foot of the Saw-tooth Mountains, of grey copper ore, a metal never before discovered in any considerable vein in that country, most valuable as an alloy for gold and silver manufactures, and in this instance singularly pure, without admixture with arsenic, iron, or zinc. The only impurity, so to speak, is silver, of which there is an amount equal in value to 16 dollars or 18 dollars per ton of ore. The vein varies from ½in. to nearly 4in. in thickness of ore. The ore yields 75 per cent. of pure metal, and its value in Europe is about 400, dollars per ton.

A report of the French Minister of Agriculture proposes the distribution of recompenses to a number of members of the Statistical Commission, established in the cantons of France in 1852, for furnishing the Government with regular local information relative to the crops, manufactures, rate of wages, and other questions concerning rural and industrial economy. His Majesty's signature approving of the suggestion is appended to the document, which is followed by a list of 1,182 persons to be so honoured. The awards consist of four medals of gold, awarded to persons proposed for the Cross of the Legion of Honour, 24 of silver, 669 of bronze of three classes, and 485 mentions very honourable or honourable.

The following statistics of the flour mills in Italy are taken from returns made to the Minister of Finance relative to the grinding tax just introduced in Italy. The total number of mills throughout the kingdom is 69,421, of which 38,000 are exclusively employed for grinding for the proprietors. Of the total number only 20,886 are continually at work. The number of pairs of mill-stones is 94,807, of which 55,986 are driven by water, 716 by steam or by wind, and 38,105 by cattle. The quantity ground amounts yearly to:—Corn, 20,619,646, quintals; maize and rye, 15,831,902 quintals; oats 109,387 quintals; other cereals, dried vegetables, and chestnuts, 1,736,818 quintals; total 38,297,752 quintals.

A few days ago, as two quarrymen, named John and Richard Stone, were working in the Kitcraft Quarry, on the Portland Heights, they had occasion to remove some stone from the "base-bed," and at 56ft. below the surface they came upon a fissure in the rock. On exploring it about 100 yards they found an opening on each side of 30 yards. Proceeding 400 yards farther, there was an opening to the upper surface, through which the light is admitted. The cavern then extends at least 100 yards further, and is altogether 600 yards in length. From the roof depend beautiful stalactites, many of them 2ft. and 3ft. long, and of different tints, some amber and others cream colour. Some curious petrifications have also been found of very fantastic shapes.

Patents for Inventions.

ABRIDGED SPECIFICATIONS OF PATENTS.

The Abridged Specifications of Patents given below are classified, according to the subject to which the respective inventions refer, in the following table. By the system of classification adopted, the numerical and chronological order of the specifications is preserved and combined with all the advantages of a division into classes. It should be understood that these abridgments are prepared exclusively for this Magazine from official copies supplied by the Government, and are, therefore, the property of the Proprietors of this Magazine. Other papers are hereby warned not to produce them without an acknowledgment:—

Boilers and Furnaces—655, 668, 686, 693
Buildings and Building Materials—700, 704, 710, 716, 723, 736
Chemistry and Photography—720, 722, 732
Cultivation of the Soil, including agricultural implements and machines—658, 691
Electrical Apparatus—733
Fibrous Fabrics, including machinery for treating fibre pulp, paper, &c.—645, 660, 675, 678, 683, 692, 696, 703, 714, 734, 735
Food and Beverages, including the apparatus for preparing food for men and animals—665, 715
Furniture and Apparel, including household utensils, time-keepers, jewellery, musical instruments. &c.—657, 667, 672, 673, 677, 680, 681, 685, 695, 702, 705, 706
General Machinery—656, 659, 674, 676, 679, 682, 687, 690, 707, 709, 718
Lighting, Heating, and Ventilating—661, 711, 712, 728, 730
Metals, including apparatus for their manufacture—699, 724
Miscellaneous—421, 635, 662, 664, 666, 669, 688, 693, 697, 698, 719, 727, 731
Roads and Vehicles, including railway plant and carriages, saddlery, and harness, &c.—663, 671, 701, 708, 717, 721, 725
Ships and Boats, including their fittings—670, 684
Steam Engines—729
Warfare—622

421 J. GREENFIELD, Down-villa, New Wandsworth, S. *Hop-scotch cloths.*
The object is to provide means in a portable manner or otherwise in the form of boards, cloths, inlaying, &c., for the purpose of playing indoor or outdoor hop-scotch or scotch-hoppers, and the invention consists in nothing.—Patent abandoned.

622 W. E. GEDGE, Strand. *Breechloaders and cartridges.* (A communication.)
The loading by the breech is effected by the aid of a main piece, termed the movable chamber. In use, this piece serves in the first place to close at the actual moment of firing the opening of the loading chamber, which is made towards the breech, while it has also for object in the contrary position to facilitate the introduction of the cartridge. It also serves, according to the position given to the lever, to determine or annul the action of the trigger. Finally, it fires the charge by the action of the striker on the cap of the cartridge.—Patent completed.

635 F. N. GISBORNE and H. ALLMAN, West Strand, W.C. *Metal tubes.* Dated March 2, 1869.
The inventors employ strips of metal coiled spirally around, so as to form a spiral tap joint. These joints or laps they either rivet, weld, solder, or braze, or they may be fastened by the process known as galvanising or tinning. By forming tubes as described, the inventors obtain a maximum amount of strength with a minimum weight of material.—Patent completed.

645 R. LAW and S. HARGREAVES, Burnley. *Warping.* Dated March 3, 1869.
This consists in warping with the heck open, that is, with the half of the "eyes" up and the others down (except when the lease is being taken), and in bringing the two sets of threads together or within about ½in. of each other at the half beer or dividing rollers by a rod plate or other suitable mechanism, arranged so as to be easily turned up or down or otherwise moved as required when taking the lease.—Patent completed.

655 W. H. TOOTH, Sen. and Jun., Greenwich. *Furnaces.* Dated March 4, 1869.
This consists in a new form and construction of the grate, or rather of the bars and bearers forming the grate, by which a peculiar and continuous motion may be given to them during the combustion of the fuel, and also in certain arrangements connected with the supply of fuel to the grate, which, while regulating the supply, also makes it self acting. The bearers or transverse bars upon which the longitudinal furnace bars rest are each formed so as to represent a series of double crank, that is to say, each bar is formed with a number of crank ends or arms on alternate sides, the number being proportioned to the number of furnace bars. A longitudinal bar having a notch or recess at each end rests with its notches upon each crank arm, so that when motion is given to the cranked transverse bearers a continuous reciprocating motion is transmitted to each of the longitudinal furnace bars.—Patent abandoned.

656 E. T. HUGHES, Chancery-lane. *Casting chains.* (A communication.) Dated March 4, 1869.
This consists in the construction of a flask divided longitudinally in quarters, and arranged so as to receive a mould board between each two of the four quarters, that is to say, so that the mould board will divide the flask both vertically and horizontally, and one half of the pattern be formed upon opposite sides of each part of the mould board, so that the links will be moulded one within the other, and when all are moulded the mould board is removed, the four parts or quarters of the flask set and locked together, and a succession of link moulds are formed in the centre into which the metal is poured to form the chain.—Patent abandoned.

657 M. G. COLE, Bexley Heath. *Watches.* Dated March 4, 1869.
This consists in placing the banking pins at the tail of the lever, and in so forming this tail as to act as a spring instead of making it rigid as heretofore, such spring being sufficiently stiff, when coming in contact with the banking pins, to limit the ordinary motion of the lever to the required extent, while it is sufficiently elastic to allow the lever to yield to the second blow of the ruby pin, and to assume its correct position after the ruby pin has passed it. In place of making the tail of the lever act as a spring, the inventor sometimes fits a spring on to the pallet staff in addition to the ordinary lever, so that the spring will act on the banking pins and yield to the second blow of the ruby pin as in the other case.—Patent completed.

658 T. HOWCROFT and A. M'GREGOR, Bedford Leigh. *Reaping.* Dated March 4, 1869.
This consists in an improved arrangement of the framework and gearing, whereby a more perfect and complete combined machine is produced, affording various great facilities for the more easy and perfect conversion of a distinct and complete mowing machine into a distinct and complete reaping machine. The invention also consists in the application of a self-acting side delivery apparatus to a two-wheeled mowing machine. The inventors prefer adopting a different arrangement of the framework and gearing, in order to admit of the better attachment of the self-delivery apparatus, and keeping the finger bar in the same relative position to the self-delivery rakes. The arrangement consists principally in giving motion to the main axle, through the two driving wheels, by means of ratchet wheels and pawls as in the combined reaping and mowing machine.—Patent completed.

659 S. MARSDEN, Manchester. *Bolts and rivets.* Dated March 4, 1869.
This consists in an arrangement whereby the pressure of the ram is enabled to be suspended or repeated at pleasure without detaching the motive power from the machine. To effect this it is proposed to connect the driving shaft to the carriage of the ram by a part which may be removed at pleasure.—Patent completed.

660 T. GREENWOOD, Leeds. *Screw gill roving frames* Dated March 4, 1869.
Instead of effecting the necessary changes of speeds as heretofore by changing the driving pulleys or the driving drum, the inventor proposes to provide a set of change wheels for varying both the speed of revolution and the transmitted speeds of the ordinary driving shaft without changing the speed of the driving pulleys.—Patent completed.

661 J. B. SPENCE, Manchester. *Purification of gas.* Dated March 4, 1869.
This consists in manufacturing muriate of iron from certain substances, whereby the said muriate is produced economically and in a suitable condition for the purification of gas. The inventor takes slag derived from the puddling furnace in the manufacture of iron or from the smelting of copper, and which are in a proto state, and grinds them by any ordinary means. He then treats with muriatic acid in a suitable vessel, using sufficient to take up the iron contained in them, and he thus obtains muriate of iron suitable for being transferred to the gas purifiers in its crude state, or it may be previously crystallized.—Patent completed.

662 T. FORSTER, Streatham, and R. TAYLOR, Kennington, S. *Printing rollers.* Dated March 4, 1869.
This consists in covering the stocks of printing rollers with vulcanized india-rubber and subsequently coating the exterior surface of the vulcanized india-rubber with gelatine or glue combined with treacle or with other analogous composition. It is preferred that the coating of vulcanized india-rubber should be in the form of what is termed sponge.—Patent completed.

663 W. MACRAE, Johnstone, Renfrewshire. *Velocipedes.* Dated March 4, 1869.
The bushes which carry the spindles of the wheels are made of brass, gun metal, or other suitable metallic substance, and a piece projects upwards from them, to which the forked part of the framing is attached by bolts, a recess being, by preference, formed in the piece projecting from the bush, and into which the end of the fork fits. The two forked bars are connected together by a bar extending from the lower end of the fork, which contains the small wheel, to the upper part of the fork, to which the larger wheel is attached. The bar is bent to the requisite form, and its lower end is also forked. The upper part of the fork of the larger wheel passes through a bush, and is mounted by a hand lever frame for guiding the velocipede.—Patent abandoned.

664 J. H. JOHNSON, Lincoln's Inn-fields. *Dyeing and printing.* (A communication.) Dated March 4, 1869.
The process consists in employing an acid bath, in which the dyed fabric is immersed, either immediately after undergoing oxidation or after the employment of an alkaline bath, the degree of concentration or strength of the acid being regulated according to the fabric under operation, and the result it is desired to obtain.—Patent abandoned.

665 W. BETTS, Wharf-road, City-road. *Marks on capsules.* Dated March 4, 1869.
This consists in the application of designs produced by what is known as the meta-chromotype process or analogous processes to the surfaces of capsules for the purpose of ornamenting the same, or for producing multi-coloured trade marks thereon. The meta-chromotype is moistened and applied to the capsule with gentle pressure, either before or after it is put on the bottle, and on removing the paper containing the design the latter will be found adhering firmly to the capsule.—Patent completed.

666 J. GOUGH, Kirby-street, E.C. *Cylinders and distributing colour.* Dated March 4, 1869.
The main feature of this invention is the construction and employment of a cylinder or cylinders in combination with a composition or other roller or rollers, whereby a uniform distribution of colour, ink, or fluid is maintained, and in the construction of the machinery or apparatus in which the cylinder is mounted. The cylinder is formed of fillets or ribs and V-shaped rings or spiral thread; it is covered with wire gauze, and distributes colour or ink placed inside on to a composition roller used in printing, with which it is used in combination. The ink is drawn through the wire gauze by the rollers in their rotation. If the cylinder is used separately it is coated with a saturable material.—Patent completed.

667 C. TIGHE, Poultry, E.C. *Studs.* Dated March 5, 1869.
The inventor forms on or fixes to the shank of the stud or button a metal plate having a number of points or projections arranged around the edge thereof, and in order to attach it to a glove or other article or garment he, by a convenient tool, makes suitable cuts or slits in the glove or other article or garment, through which slits or cuts the head of the stud or button and the points or projections, which have been previously turned up at right angles, are passed; then, by a suitable tool, the points or projections are turned over flat on to the material to which the stud or button is to be fixed, a piece of leather or other suitable material being fixed over the back of the plate carrying the points or projections.—Patent completed.

668 C. D. ABEL, Southampton-buildings. *Injectors.* (A communication.) Dated March 5, 1869.
The steam cone is provided with a regulating spindle by screwing which to a greater or less extent into the cone the supply of steam is regulated. The cold water is introduced through a branch pipe behind the combining cone while the hot water is introduced through a side aperture in a casing or chamber surrounding the combining and receiving cones. The combining cone is secured by a flange at the end thereof, being held between a shoulder on the casting containing the steam and water passages (in which casting the steam cone is screwed) and the one end of the before-mentioned casing which is screwed into such casting.—Patent abandoned.

669 F. WINDHAUSEN, Brunswick, Germany. *Ice making.* Dated March 5, 1869.
The inventor employs a single double-acting cylinder or two distinct cylinders, the double-acting cylinder being capable of compressing the air on one side of the piston and of expanding it on the other, whilst when the two cylinders are employed one is used for compressing the air and the other for expanding it afterwards. The air is first admitted into the compressing chamber and thence passes into a condenser, which forms a material part of this invention and consists by preference of a rectangular chamber divided into two portions or divisions having a parallel series of pipes in each division, the nearest series of such pipes to the compressing chamber through which the air first passes being surrounded by cold water, which is constantly running through it in an opposite direction to the current of air so as to cool the air passing through such pipes, the second series of such pipes through which the air next passes being surrounded by cold water.

670 W. E. GEDGE, Strand. *Iron ship preservers.* (A communication.) Dated March 5, 1869.
This consists in transforming the ship into a vast electric battery, nearly similar to a trough battery, which is effected as follows:—First, on the inner sides of a ship are established zinc reservoirs, either in the form of cases, the position of which will be regulated by the interior arrangement of the vessel, or in the form of a tube, making a complete or incomplete circuit round the ship. Second, these reservoirs, which may vary in form, are constructed exclusively of zinc, leaving a small section, which can be filled up either by the inner side of the ship, if it is of iron, or by a sheet or band of the same metallic nature as the sheathing to be preserved if the vessel be sheathed. Third, these reservoirs are in perfect electric communication with the metal to be preserved by means of bolts, rivets, or other contrivance, always, however, of the same nature as this metal. Fourth, various parts of the reservoirs will be connected together at certain distances by bands of zinc, crossed diagonally by other bands of the same metal, so as to render the whole body of the ship uniformly subject to the same action. These bands should be also in perfect electric communication with each other and with the metal intended to be preserved. Fifth, some sheets of zinc in communication with the reservoirs are placed on the exterior a little below the float or water line, but so that they may be easily changed or removed when required. Sixth, at the upper portion of the reservoir apertures are formed of sufficient size to give vent, if necessary, to the gases which may be disengaged in the interior. Seventh, the reservoirs are filled daily with sea water, acidulated water, or with any liquid possessing identical properties. Eighth, a clock placed upon the lowest part will serve as an escape for the waste water. Ninth, by the aid of a current of water all the apparatus may then be washed. Tenth, a movable cover of sufficient section is also placed at a certain point of the reservoir, so that from time to time a cleansing can be made by any mechanical contrivance.—Patent completed.

671 H. KNIGHT, Ryde, Isle of Wight. *Horse clipping* Dated March 5, 1869.
This apparatus consists of a flat plate of metal, one edge of which is provided with teeth arranged like the teeth of a comb. This plate, when the instrument is used, rests upon the skin of the horse, the hairs to be clipped or cut off standing up between the teeth. Upon the said toothed plate a cutter or series of cutters works, the said cutter or cutters cutting off the hairs against the edges of the teeth of the said toothed plate.—Patent abandoned.

672 H. A. BONNEVILLE Sackville-street, W. *Necktie fastening.* (A communication.) Dated March 5, 1869.
This consists in a little metal or other plate, of any convenient form, on which the article is sewn or otherwise fixed, and at the centre of which exists a slight swelling, wherein lodges the button, and which is furnished with a little slot through which passes the rod or the threads, fixing the button to the shirt collar.—Patent abandoned.

673 C. E. BROOMAN, Fleet-street. *Fur fabric.* (A communication.) Dated March 5, 1869.
This consists in introducing strips of the furs of animals or the down of birds into fabrics during the process of weaving, whereby a curved or down fabric is produced which may be of varied design, shade of colour, or thickness. The strips of fur or down employed may be thin or narrow and in different shades, and are inserted in the warp either close together or at a distance apart, whereby a regularly furred fabric is obtained, and one more or less thick, according to the quality desired.—Patent abandoned.

674 W. B. WATERLOW, London Wall. *Stamping pres* Dated March 5, 1869.
This consists in constructing the frame of such presses with a lever piece hinged or jointed to the lower part of the frame. This lever piece as it extends upwards is fitted or made with two arms, which arms extend towards the upper part of pillar of frame, such part of the pillar being curved or inclined in the direction of the arms. These arms are for the purpose of receiving a spindle, on which is carried the ink duct and surface for inking the type or die. The inking duct is carried or fitted in such manner upon this spindle that it is capable of being moved within certain limits around it, or so as to make a small portion of a revolution upon it.—Patent completed.

675 J. HOLDING, Manchester. *Looms.* Dated March 6, 1869.
This relates, first, to the "temple," and consists in extending the centres between the back and front rollers of the present two-roller "temple." Second, to a new and improved arrangement and adaptation of mechanism to be employed in connection with the "reed," for slowly raising and lowering the latter during the time the warp yarns are passing between the "reed dents," making them thereby more durable. This is accomplished by connecting the weighted levers of the cloth roller with the under frame of the reed in the "lathe" by elbow levers and connecting rods, that will allow the "lathe swort" freely to vibrate.—Patent abandoned.

676 J. LOADER, Upper Clifton-street, E.C. *Rotary engines.* Dated March 6, 1869.
The engine is constructed as follows:—Through a cylinder the inventor places a central shaft or axis, having a crank pin or eccentric formed on or carried thereby, and upon the crank pin or eccentric he fits a disc which is capable of revolving thereon, and the periphery of which fits against the inside of the cylinder. In the cylinder he cuts a slot, in which a stop or abutment slides. This stop or abutment may be in a line radiating from the centre of the cylinder or inclined thereto and such stop or abutment is connected to the disc or piston by a stud or pin, which is received into a suitable hole formed for it in the disc or piston, or it may be connected thereto in other convenient manner.—Patent abandoned.

677 R. BADGER, Sawbridgeworth Hertford. *Shears or scissors.* Dated March 6, 1869.
The object is the construction of scissors and shears, to be used by pressing downwards against the surface on which the fabric to be cut is laid. For this purpose the inventor places above the blades a handle, which upon being pressed down closes the blades, and the same can be opened by a spring (when the downward pressure is released). The handle should be so arranged that it may be attached to the upper blade, and be connected to the shank of the other blade.—Patent completed.

678 W. S. MELDRUM, Leeds. *Carding engines.* Dated March 6, 1869.
This consists in the application to carding engines of sets of rotating blades or beaters mounted on axles and made to work in the outer interval between the two rollers, commonly called the workers and the strippers. —Patent completed.

679 J. B. Spence, Manchester. *Purification of gas.* Dated March 6, 1869.

This consists, first, to the production of muriate of iron suitable for the extraction of sulphur and ammonia from gas. To effect this the inventor takes the spent oxide of the purifyers and drives off the sulphur by any method now practised. Or he takes pyrites from which the sulphur has been driven off in the ordinary manufacture of sulphuric acid, and treats them with muriatic acid, preferably with heat.—Patent abandoned.

680 A. Morrall, Studley. *Needle threader.* Dated March 6, 1869.

The needle threader consists substantially of a piece of flattened wire, having at the one end or point thereof a kind of hook or projection for the purpose of grasping and holding the thread.—Patent completed.

681 T. Ross, jun., Glasgow. *Slide for magic lanterns.* Dated March 6, 1869.

This consists in the combination of two discs or wheels, one of glass, or any other transparent substance on which pictures are painted, drawn, printed, or photographed, the other wheel being made of metal, wood, or any opaque substance, in which wheel openings or slits are formed converging to the centre. The object of this combination is to produce the effect of moving figures, chromotypes, or other objects, by placing the two wheels or discs on an axle and revolving them in contrary directions, by means of pulleys, wheels, or other means.—Patent abandoned.

682 H. and J. Ellis, Salford. *Cranes.* Dated March 6, 1869.

The inventors employ, in addition to a large pulley and endless chain, two chain pinions, one on a shaft having a handle, and the other on a lever which can be moved to and fro, and on the shaft there is a ratchet wheel, which can be held by a catch.—Patent abandoned.

683 W. G. Simon, Oakley-square. *Hanks.* Dated March 6, 1869.

This consists in applying friction rollers to hanks for hoisting and lowering fore and aft sails. The improved hank is composed of a circular disc of metal or other material, around the inside of which is arranged a series of friction rollers revolving on spindles or pins fixed in the disc, or the spindles and rollers may revolve together when required, a circular space being left between the peripheries of the rollers for the stay to pass through.—Patent abandoned.

684 R. R. Bevis, Birkenhead. *Screw propellers.* Dated March 6, 1869.

In order to be enabled to feather the blades of a screw from within the ship so that they may be brought in a line fore and aft or any intermediate angle a sliding rod is employed passing through a hole bored through the centre of the last length or lengths of shaft. The inner end of the sliding rod is fitted with a crossbar which passes through a slot in the shaft into a recess in a large nut, which embraces the shaft and works on a screw thread cut on the shaft and gives the required motion to the sliding rod.—Patent completed.

685 A. M. Clark, Chancery-lane. *Envelopes, &c.* (A communication.) Dated March 6, 1869.

The inventor makes the envelope of paper, linen, or other suitable material, and of such form that the water, wax, gum, or other substance employed for sealing will adhere both to the envelope and its contents. The envelope may be thereby firmly attached to the contents so that their separation would destroy the seal connecting them, the traces of which would remain on the contents.—Patent completed.

686 A. Dixon, Railway-place, E.C. *Steam lubricators.* Dated March 8, 1869.

This consists in fixing a stand pipe into the inside plug of the apparatus known as a hollow plug grease cock, thus enabling the apparatus when so constructed to lubricate by displacement when this inside plug is turned round so as to bring the stand pipe over, and upright, or nearly so, with the discharging hole in the outer shell or casing leading to the steam. The inside plug is further provided with one or more holes for filling, and suddenly discharging and emptying, all of which operations can be performed as desired by the same handle or hand wheel acting upon the inside plug and causing it to revolve, brings the holes to their proper positions for each operation. The holes are placed in the inside hollow plug in such positions relative to the other and to the stand pipe that no two of them can at any one time be open together.—Patent abandoned.

687 J. L. M'Elroy, Glasgow. *Pumping and measuring.* Dated March 8, 1869.

The apparatus comprises a cylindrical chamber formed by a flanged cylindrical casting, to which end covers are bolted, and which is formed with feet whereby it is bolted down to a bed frame. Inside the chamber there is an elliptical or approximately elliptical boss or drum, fixed eccentrically on a central shaft extending out through stuffing boxes in the end covers. The boss touches the cylindrical surface of the chamber, and has a strip of metallic packing pressed out by springs applied at the point of contact whilst it revolves like a piston. There are abutments or sliding stops which are opposite to each other in the same diametrical line, and which, extending out through stuffing boxes, are connected together by external crossheads and rods so as to work together, and so that as one is pushed out by the action of the eccentric boss it causes the other one to move inwards, the inner ends, or rather metallic packing strips, fitted thereto, being always in contact with the boss.—Patent completed.

688 J. B. Rowcliffe, Manchester. *Wire cloth.* Dated March 8, 1869.

This consists in weaving wire cloth so as to produce a twilled or fancy surface. In order to make the wire cloth run more evenly on the paper making machine, the inventor reverses the direction of the twill in the warp at intervals as often as may be required.—Patent abandoned.

689 W. Burr, King Edward-street, E.C. *Compressed leather.* Dated March 8, 1869.

Instead of leaving the surfaces of the compressed leather in an unprotected state, one or both of the surfaces thereof is or are coated with a composition capable of resisting the influence of moisture, and of preventing the same from being absorbed by the leather. This composition consists of a mixture of vegetable black, boiled oil, and litharge.—Patent abandoned.

690 W. A. Gilbee, South-street, E.C. *Raising water.* (A communication.) Dated March 8, 1869.

The apparatus or pump consists of a wheel furnished with one or more hollow cylinders closed or not to the water, and with a number of paddles or arms. It is suspended on its shaft, and enclosed between three walls or partitions of masonry or other suitable material, and separates directly the up water from the down water when no valve is placed before the wheel on the side of the up water. In turning on its shaft the circumference of its outer cylinder forms the movable side or partition of a pump body; the three other sides formed by the masonry are fixed, thus forming a pump with rotary pistons, which, without pipes, valves, or other accessories, raises the down water into the up water without any unnecessary elevation, whatever be the levels and the speed of the wheel.—Patent completed.

691 J. Pitt and Brothers, Cleckheaton. *Drilling.* Dated March 8, 1869.

This apparatus consists of a rotary spindle mounted in a headstock fixed upon a suitable bed or frame, and on one end of which is fixed a drill cutter or shaping instrument suitably formed for the purpose required to be effected. On this spindle are also ordinary cone pulleys for driving the same.—Patent abandoned.

692 C. Mather and W. Rossetter, Salford. *Warping.* Dated March 8, 1869.

This relates, first, to warping machines having self-stopping motions for stopping the machine when one or more of the warp threads break, and further consists in improvements upon an invention for which letters patent were granted to W. Rossetter, dated October 7, 1868 (No. 3,061). Second, the invention consists in various improvements applicable to all descriptions of power looms used for weaving, and also for further improvements upon an invention for which letters patent were granted to W. Rossetter, dated October 13, 1866 (No. 2654).—Patent completed.

693 C. Fairbairn, Edinburgh. *Furnaces.* Dated March 8, 1869.

This consists in arranging in the angle of the furnace bars perforated firebricks and hot-air passages which are led towards a hollow hanging bridge in the furnace, whereby the combustion of the unconsumed gases is rendered more complete and the formation of smoke prevented.—Patent completed.

694 L. M. Ruiz, Paris. *Clarifying oils.* (A communication.) Dated March 8, 1869.

This consists in the employment of several materials and apparatus for obtaining a proper clarification and purification of all sorts of oils, whereby the processes hitherto employed are much simplified. Thus for all mineral oils extracted from coal, or those of various natural production, called petroleums, as well as such as are extracted from vegetable or animal matter, the same result is obtained in their purification by employing a filter of whatever form, and filled with natural powder of calcined mineral coal, such as schist or lignite or tripoli clay, argil, or other minerals. By preference the inventor employs such minerals as contain either in their natural state or by admixture at the time of calcination, a carbonic principle mixed with phosphate or carbonate of lime, or of potash and sulphate of iron.—Patent completed.

695 H. Tylor, Queen-street, E.C. *Spring bottoms for bedsteads.* Dated March 8, 1869.

This consists in fitting the springs composing the bottom between a bar at the under side and a lath at the upper side of the springs. The ends of the bars are secured by pins on their ends being dropped into holes in any convenient manner in a bar or bars fitted parallel to and under the ordinary angles or side rails, while the laths are secured by studs or other connections to the angles or side rails in the ordinary way, and with which they are almost level. The springs being secured in the manner above described can be removed with the bar and lath to which they are attached without interfering with the other springs, bars, and laths.—Patent completed.

696 P. Buchan, Green Island, Belfast, and A. Guild, Belfast. *Preparing jute.* Dated March 8, 1869.

The inventors first steep the fibre in a solution of either soda, potash, or ammonia, by preference heated to 80deg. or 90deg. Fah., or it may be cold, and for such length of time and employing such strength of alkali as from the character of the fibre may be found necessary. After such steeping the fibre is exposed to a bleaching solution of either chloride of lime, soda, or magnesia, or to the action of chlorine gas, but, by preference, to that form of bleaching solution known as Jauvelle water, until the required lightness of colour is obtained. The fibre is next washed to rid it, as far as possible, of the bleaching liquor, and it is then steeped in a weak solution of sulphuric or hydrochloric acids, marking (say) 1deg. Twaddell, for from two to three hours. When removed from this solution it is placed in an oil bath prepared from a mixture of vegetable oils and carbonate of potass, from which it is taken and dried.—Patent abandoned.

697 J. A. Jaques, J. T. Oakley, and J. A. Fanshawe, Tottenham. *Grinding and surfacing.* Dated March 8, 1869.

This consists in rendering the chuck temporarily magnetic, so that when the rings, plates, discs, or other articles are placed thereon they will be held firmly against it by the magnetic attraction, which may be produced in any of the well-known ways of rendering iron temporarily magnetic.—Patent completed.

698 H. W. Cook, Ovington square. *Clocks.* Dated March 8, 1869.

This consists in the application of electrical regulators to various kinds of clocks, which are or may be worked in the ordinary manner, either by weights or springs, or by any other means except electricity, the electrical agency to be employed merely serving to regulate the action of the clocks, which are to be driven by other power.—Patent completed.

699 J. P. Budd, Ystabfera, Swansea. *Iron and steel.* Dated March 8, 1869.

The object is to subject molten cast iron to the action of nitrate of soda and soft hematite, iron ore, or other oxide of iron previous to its being subjected to the puddling process. For this purpose the inventor runs the molten cast iron into shallow pans capable of holding from 3in. to 5in. in depth of melted metal and lined with a paste composed of a mixture of the materials above mentioned, or of either of them separately. When the fluid metal is poured into the pans a violent ebullition takes place, and a large proportion of the silica, together with some of the carbon, phosphorus, and sulphur contained in the iron, is carried off in the slag, so that when the slabs of purified metal are subsequently worked in the puddling furnace the puddling operations are effected much more rapidly than with ordinary pig iron, as when puddling ordinary pig iron in a puddling furnace but a very small proportion of carbon is separated from the iron before the greater proportion of the silica is eliminated.—Patent completed.

700 R. F. Piltz and T. H. Lee, Newnham-street, W. *Paper hangings.* Dated March 8, 1869.

This consists in coating strong well sized paper with oil colours spread upon the surface of the same by an apparatus charged with the colouring matter, so that on the paper being drawn longitudinally beneath the apparatus (which is mounted horizontally upon a fixed bench or table), the colour is caused thereby to flow evenly over the surface.—Patent abandoned.

701 R. Turnbull and J. G. Piton, Cowper's-court, E.C. *Signal for trains and ships.* Dated March 8, 1869.

Steam pipes are placed underneath the framing of the carriage immediately over the centre line, to convey the exhaust steam from the cylinder or other part of the engine to the end of the train or carriage. In the centre of each carriage, placed between and connected to the pipes, is a steam whistle; pull cords or wires leading from each compartment are connected to the handle of the whistle, such whistle also forming a stopcock. When the engine first discharges the exhaust steam it enters the pipes and is conveyed through them to the end of the train, the stopcocks being all open, but in case of danger or signalling being required to be made, then by pulling a cord or wire the cock is shut and confines the steam, causing a great pressure against the whistle, giving instantaneous alarm through the whole train, and commanding the engine driver to stop, the whistle sounding so long as the engine discharges steam.—Patent abandoned.

702 T. Baker, Buckingham-villa, Stratford, E. *Umbrellas.* Dated March 8, 1869.

This consists in the use of ribs and stretchers made of metal, either rolled or twisted, or drawn spirally or plaited. For example, the inventor may take a strip of metal and pass it around a rod in such a manner that it shall form thereon spirals or convolutions, and when the rod is withdrawn, the strip of metal will retain the form thus imparted, and be, in fact, a spiral tube, from which a rib or stretcher may be made.—Patent abandoned.

703 W. B. Thompson, Dundee. *Textile fabrics.* Dated March 8, 1869.

Rollers for picking cloth which may be either made of wood or iron, and the circular surfaces of which are filled with teeth or spikes set at a tangent or nearly so to the circumference of the rollers. The spikes or teeth may be put through either leather, wood, iron, or other material, and then fixed on the rollers, or they may be driven direct into the roller itself.—Patent abandoned.

704 A. Mitchell, Leith. *Cutting and dressing stone.* Dated March 8, 1869.

The apparatus is contrived to operate with dressing tools or chisels, and to actuate these instruments in a manner closely approximating to that in which the mason works them. The chisels in connection with hammers for striking them are arranged so that they may be adjusted at any inclination to the surface of the stone to suit the varying qualities of the stone, and the motion when struck is regulated by specially arranged guides, in such a way that their points move as nearly as possible in lines coinciding with the intended surface of the stone.—Patent completed.

705 W. Saunders and C. Smith, Newgate-street, E.C. *Dressing bags.* Dated March 8, 1869.

This consists in an improved detachable frame made of two upright end pieces united at the top by a cross piece extending from end to end of the bag. The end pieces are provided at the bottom with feet, which rest on bars or plates permanently fixed inside the bag at the bottom thereof. To each of these bars is attached two sliding bolts formed with catches, which secure the feet of the end pieces, and with projections arranged to be operated upon by a vertical rod extending to the top of the same, and are provided with heads or buttons at the mouth of the bag. The sliding catches are held by springs, and are operated to release the frame by pressing the heads of the rods.—Patent abandoned.

706 W. Saunders and C. Smith, Newgate-street. *Chess and cribbage board.* Dated March 8, 1869.

The board or table top, which may be of any desired size, is like an ordinary chess board made of two parts, hinged together at the middle of the board, the interior of the board forming a tray, which may be provided with backgammon points or fitted for some other games, or if preferred left quite plain. The chess squares are preferably perforated to receive pegs, which are formed on the bottom of the chess men, and are inserted in the said holes to prevent the disarrangement or interruption of the game by the motion of a vessel or vehicle whereon the board is used.—Patent abandoned.

707 W. R. Lake, Southampton-buildings. *Reciprocating and rotary motion.* (A communication.) Dated March 9, 1869.

The invention is divisible into two parts. The first division relates to the particular construction of shackle bars or link rods, which connect the treadle with any suitable pawl and ratchet mechanism for working the shaft, and the second division relates to an improved friction pawl, particularly adapted to be used in combination with the peculiarly constructed linkrods above mentioned.—Patent completed.

708 F. F. Villepigue, Northampton-street, W.C. *Velocipedes.* Dated March 9, 1869.

This consists in the application of revolving plates or pieces, which convert the sliding or rubbing together of the parts into a rolling motion, unattended by friction, the plates or pieces being free and revolving within a box without being fixed at their extremities by any pieces which could connect them together and thereby occasion friction.—Patent abandoned.

709 W. R. Lake, Southampton-buildings. *Tilt hammers.* (A communication.) Dated March 9, 1869.

This relates to that class of machines known as power hammers, and consists in a combination and arrangement of devices for communicating the power to the hammer, also in the arrangement for hanging, operating, and controlling the hammer, and the changing of the hammer dies, both in the hammer head and in the anvil.—Patent completed.

710 R. BRIGGS, Leeds. *Regulating temperatures of rooms.* Dated March 9, 1869.

Between two parallel vertical standards secured to a suitable table, the inventor places a T cylinder upside down and charged with mercury. To the upper portion of such cylinder he connects a double-flanched joint and gland furnished with a piston. Between the connecting flanges of the cylinder and joint, he places a diaphragm of stout indiarubber, which separates the one from the other. To the upper end of the piston he connects a horizontal lever having its fulcrum upon a convenient projection from the framework.—Patent abandoned.

711 J. J. SHEDLOCK, Camden Town. *Wet gas meters.* Dated March 9, 1868.

This relates to the mode or method by which the water level is maintained at the proper height, thereby ensuring correct registration. For this purpose, a tube is provided having a partition fixed diagonally in the interior and two apertures made therein, one on either side of the partitions. The tube is held vertically at its ends by two stuffing boxes fixed on the upper and lower parts of the chamber in which the tube is placed. The upper end of the tube communicates with the square front of the meter, and the lower end with the overflow or waste water chamber. The lower part of the chamber containing the tube communicates with the drum case below the water line, and the upper part of the tube chamber with the gas passage from the inlet pipe. The float carrying the inlet valve is adjusted to the proper height by means of a nut fixed in the lower part, and a screw, on the upper part of which is fixed a valve.—Patent completed.

712 J. J. SHEDLOCK, Camden Town. *Dry gas meters.* Dated March 9, 1869.

This relates to improvements in dry gas meters, the diaphragms of which are so constructed that when distended they take the form of truncated pyramids, the sides of which are leather or other like flexible material. Metal frames forming the lower bases, and plates of metal forming the upper bases, are securely attached to the flexible sides, double hinge joints connect the plates of metal forming the upper bases to vertical rods, the lower ends of which work in studs fixed in the bottom of the meter, and the upper ends are supported by and work in stuffing boxes attached to the valve plate.—Patent completed.

713 H. A. BONNEVILLE, Paris. *Porcelain.* (A communication.) Dated March 9, 1869.

This process consists in mixing in equal quantities kaolin and gypsum, and in adding thereto pulverised charcoal or an analogous pulverised substance done away with in the baking in variable quantity according to the degree of porousness desired. The mixture of these substances is effected by the usual means, and by adding water in sufficient quantity to obtain a paste of such consistency as to be able to mould the same into any convenient form, according to the use and application for which it is intended.—Patent completed.

714 H. MASON, G. HARTLEY, and J. HINDLE, Bradford. *Looms.* Dated March 9, 1869.

The object is to obtain increased steadiness and certainty in working. For this purpose the inventors apply an extra swell, or other suitable elastic retaining means, adapted to act on the picker to steady it after picking the shuttle from one side to the other. These retaining means will admit of the picker passing it in picking, but it prevents the too free rebound, and retains it in position better to receive the shuttle from the opposite side.—Patent completed.

715 I. HUDSON, Stockport. *Cask tilts.* Dated March 9, 1869.

The casks or barrels are placed on the ordinary stillages, and above each cask or barrel a double lever or steelyard is suspended by a link to a bar or rail at the upper part of the cellar or other elevated position; on the arm there is a weight which can be adjusted and held at any required position, and the other arm is formed as a quadrant to which is linked one end of a chain, the other end of which is passed through one eye of a hook having two eyes, and then turned up and hooked to one of the ends of the cask or barrel. Through the other eye of this hook is passed another chain having at one end a hook which is hooked to the other end of the cask or barrel, and the end of this chain passed through the eye is turned back and hooked to the same chain to the length required.—Patent completed.

716 J. DICKIE, Glasgow. *Uniting parts of grates.* Dated March 9, 1869.

This consists in placing iron pins and screws in the moulds, so that the parts are cast with the holes in them, whilst the pins and screws are easily removed from the castings afterwards, the latter by unscrewing them.—Patent abandoned.

717 B. HUNT, Serle-street, Lincoln's Inn. *Locomotives.* (A communication.) Dated March 9, 1869.

This improved locomotive is similar in its general arrangement to the tender locomotives employed on railways. It is principally adapted for the transport of goods at a slow speed. By a modification consisting of a simple change of wheels easily performed, it can be transformed into a passenger engine with double speed. It is carried on a frame formed of longitudinal and transverse beams, and is suspended by springs on the driving and guiding wheels. The boiler and water tanks are completely independent of the mechanism, and easily dismounted. The mechanism placed under the boiler is within the longitudinal frames, and is provided with reversing gear and a brake. The furnace is placed at the same end as the fore carriage, which brings the engineer and conductor together; they being both covered by the same roof, and having within reach all the driving gear, can help each other if need be.—Patent completed.

718 W. R. LAKE, Southampton-buildings, Chancery-lane. *Turbines.* (A communication.) Dated March 9, 1869.

This consists, first, in constructing a waterwheel with two series of buckets, both receiving the water horizontally, one series discharging the water vertically and the other discharging the water towards the centre of the wheel. Second, in enclosing the wheel in a metallic case consisting of a crown plate with a horizontal flange and a cylinder having at its upper end a horizontal flange, a series of oscillating gates of a *cyma reversa* form placed between the parallel flanges and a series of shouldered bolts connecting the flanges. The wheel shaft has its support on a bridge tree bolted to the cylinder, and is maintained in a vertical position by a sleeve or by brackets attached to the crown plate.—Patent completed.

719 A. M. CLARK, Chancery-lane. *Umbrella coverings.* Dated March 9, 1869.

Fabrics suited for the above purposes are produced in various ways. Thus, first, two fabrics of different colours or aspects may be superposed either before or at the time of use, and united by sewing, pasting, or other means. Second, two fabrics of different colours or aspects may be superposed and united by weaving them simultaneously.—Patent completed.

720 H. W. GOLDRING, Moorgate-street. *Soap.* Dated March 9, 1869.

This consists in the use of a machine or apparatus of the following construction:—The pan, which is somewhat of the ordinary shape, with a hemispherical or dished bottom surrounded by a jacket, into which steam is admitted, as commonly practised, and at the centre of the pan an upright revolving shaft is adjusted, through which three or more horizontal rods or bars pass one above the other. These rods or bars are connected to and revolve by their ends in two upright flat bars of metal made of the same shape as the sides and bottom of the pan against which they fit nearly close and move freely. The bottoms of these bars are firmly connected together by another bar fitting the extreme bottom part of the pan, and this bar is fixed to the upright shaft and moves therewith.—Patent abandoned.

721 G. GOLDSMITH, Leicester. *Railway signalling.* Dated March 9, 1869.

Beneath the seat and either above or below or partly above and partly below the floor or other convenient situation a cylinder closed at the bottom and by preference made of metal is attached to the carriage. This cylinder is fitted with a piston and piston rod, the rod being carried up the back or partition dividing the compartments to which it is held by a spring, bolt, or other suitable contrivance. At the bottom or lower side of the cylinder an outlet is made, which by means of a metal pipe screwed or otherwise fastened thereto leads to the next cylinder. The pipes at the end of each carriage are however carried some distance up the outside of the back thereof, where they each terminate in a socket, and in order to connect the pipes of each carriage together recourse is had to a flexible pipe having metallic plugs at each end which can be inserted in the sockets before mentioned and retained in position by a bayonet catch or other appropriate fastening, such, for instance, as a short metal pipe with a stud on the exterior passing into a pipe of slightly larger diameter with a slit to receive the stud and fitted with a leather disc which will surround the interior pipe so as to make a close joint.—Patent abandoned.

722 G. H. T. FINZEL, Bristol. *Cooling charcoal.* Dated March 9, 1869.

The inventor cools and sifts animal charcoal after it has been reburnt, and at the same time raises it to the desired elevation by feeding it into a pipe or shaft up through which a current of air is caused to pass. The current of air is sufficiently rapid to carry the charcoal along with it, and the charcoal is by this means raised to the desired height at the same time that it is cooled; the upper end of the pipe or shaft opens into a chamber, and the charcoal as it issues from the shaft or pipe falls upon the floor of the chamber, whilst the dust passes off with the air into a second chamber, where it is collected.—Patent completed.

723 R. M. CAFFALL and D. MILLER, Alton. *Wall waterproofing.* Dated March 9, 1869.

The inventors prefer to take paraffin in its solid state and subject it to the action of heat by melting it in a metallic or other suitable vessel. When thoroughly liquefied they apply it by means of an ordinary brush such as is used by painters to the wall or other surface desired to be protected. Sometimes the inventors previously warm the wall or other surface with what is known as a "painter's stove" or "devil," and after the liquid paraffin as above described has been applied they again use such "stove" or "devil" to liquefy and force in any paraffin remaining visible on the exterior of such wall or surface.—Patent completed.

724 J. HENDERSON, Auchencairn. *Iron and steel.* Dated March 9, 1869.

The puddling furnace may be termed a double reverberatory furnace, as the hearths are arranged two deep, being placed back to back so as to receive their heat from one and the same fire chamber. In this chamber the inventor uses waste or small coal as fuel with a blast of air on each side which consumes all cinder and enables the heat to be kept up night and day without any stoppage whatever from cleaning or renewing the fire.—Patent completed.

725 J. EDWARDS, Hackney. *Permanent way.* Dated March 9, 1869.

This consists in applying a tube to railway trains. Into this tube the inventor inserts whistles, to be blown by passengers, the tube being open throughout. The current of air passing through the tube carries the sound of the whistles with it into the guard's van. The invention also consists in the application of a rope (or its equivalent) to railway trains with elastic connections suspending weights. This rope is coupled when necessary, and in order to give the signal it is only necessary to uncouple the rope and set the weights at liberty, which then fall, and in their fall ring a bell.—Patent abandoned.

726 W. SAUNDERS and C. SMITH, Newgate-street, E.C. *Dressing case and bag.* Dated March 9, 1869.

This consists chiefly in the peculiar construction of the parts of the case and bag, whereby the inventors are enabled to combine in one article the advantages of an ordinary separate dressing case, a compact and convenient dressing bag. The whole of the fittings and instruments are carried within the case, which is preferably made of a semicircular form in cross section, the flat side forming the base. The bag is made to contain the case, and to allow the same to be readily and conveniently placed in the bag or removed therefrom.—Patent abandoned.

727 G. SPENCER, Cannon-street, and J. BARKER, Mortlake. *Provision preserver.* Dated March 9, 1869.

This consists in placing the substance to be preserved in an airtight vessel, from which the inventors withdraw the atmospheric air contained therein, and refill by an atmosphere of nitrogen, in which decomposition cannot take place.—Patent completed.

728 T. OBACH, Manchester. *Fuel economiser.* Dated March 9, 1869.

The inventor forms upon the pipe and near the end thereof two or more studs or projections to pass when the pipe is inserted into the socket. These recesses open into a groove or grooves, and a shoulder or face is provided in the socket corresponding to the face on the end of the tube.—Patent completed.

729 W. WALKER, Newton Heath. *Expansion slide valve gear.* Dated March 9, 1869.

This consists in the method of actuating the cut-off plates of such slide valves so as to use the steam expansively by means of a novel adaptation to the purpose of the well-known archimedian screw, which is mounted in a suitable bracket or pedestal, and has a square formed upon its extremity to prevent it turning in its bearing in the bracket or pedestal, and is jointed to the governor at the other extremity, so as to move in the direction of its length by the action of the governor, but not to turn upon its axis, thereby removing all strain from, and not interfering with the correct action of the governor.—Patent completed.

730 W. R. LAKE, Southampton-buildings, Chancery-lane. *Self-lighting gas burners.* (A communication.) Dated March 10, 1869.

This consists, first, in confining a coil of platinum wire or its equivalent with a gas burner in such a manner that it will cause the re-ignition of the gas if the latter should be extinguished without shutting off the flow. Second, in supporting the said platinum coil or its equivalent upon a ring which may be cast upon the wire or secured thereto in any other manner, and is adapted to fit around the gas tip or burner. Third, in combining a cap or hood with a self-lighting gas burner or self-lighting attachment.—Patent completed.

731 B. BRITTEN, Red Hill. *Whips.* Dated March 10, 1869.

Instead of employing wood or the other material now generally used for the sticks or pliant stems of whips used for riding or driving, the inventor makes use of steel, iron, or other metal. The metal he uses in the form of light tubes, or of other shape which will give the strength, pliancy, and lightness. The thong is attached as usual, and may be of the ordinary kind. To prevent the metal from rusting he gives it a coating of japan lacquer or other varnish or paint, or by means of the electro or other process he gives it a coating of gold, silver, tin, or other metal.—Patent completed.

732 W. WELDON, Highgate. *Manufacture of chlorine.* Dated March 10, 1869.

This relates, chiefly, to the regeneration or other production, in the wet way, from residual products of the manufacture of chlorine, of certain compounds containing peroxide of manganese, and to the manufacture of chlorine by means of such compounds so regenerated or produced.—Patent completed.

733 J. SAX, Great Russell-street, W.C. *Telegraph receiving instruments.* Dated March 10, 1869.

Two metal plates are framed together by pillars, so as to be one over the other about 1¼in. in distance apart, the bottom or larger plate being about 4in. square and the top 3in. The inner side of the top plate carries a small ratchet wheel in the centre, about ½in. in diameter. This small wheel has fourteen or fifteen teeth, according to requirement, while the bottom plate is about 1in. from the top edge in a direct line with the axis of the small wheel on the top plate, and is suspended perpendicularly by an axis passing through the centre of the same. A light bar magnet has affixed to either side of it two light steel springs. These springs pass about ½in. beyond the extreme end of this light bar magnet. They are parallel to each other, but so fixed that the inside edge of each are in the same place, as the ends of these presents would have a tendency to press downwards towards each other. The bar magnet has, therefore, a small piece of brass fixed on the extreme end of it with two set screws, each screw facing one of the springs from the inside, so that by setting the screw each spring may be adjusted to the proper position.—Patent completed.

734 W. KNOWLES, Bolton. *Spinning mule.* Dated March 10, 1869.

This consists in supporting the yarns by means of a wire, distended by arms or levers, which are raised and lowered by a rail fixed to the floor, or in any other convenient manner.—Patent abandoned.

735 R. RULE, Glasgow. *Weaving ornamental fabrics.* Dated March 10, 1869.

This consists in weaving the fabric in such a way that the stripes appear to be of a texture or material quite different from that of the remainder or ground of the fabric, and this is done by making the cloth "double" at the stripes.—Patent abandoned.

736 C., W., and J. DRAKE, New Kent-road. *Breaking stone for concrete.* Dated March 10, 1869.

The inventors employ rollers with corrugated surfaces. The grooves run around the rollers with their sides parallel, and the grooves in one roller are set to correspond with the projections or ridges on the other. The rollers are mounted horizontally on parallel axes. They are caused to rotate by powerful driving gear, and the material to be broken is fed in between them. The ridges may have ratchet-like teeth or grooves cut upon them to cause the rollers to take down the materials between them with greater certainty.—Patent completed.

APPLICATIONS FOR LETTERS PATENT.

Dated September 21, 1869.

2739 H. and F. C. Cockey, Frome Selwood, Somersetshire. Improvements in apparatus for scurfing retorts.

2740 J. Elce, Manchester. Improvements in the shape and manufacture of bobbins or spools, and in the machinery for winding rovings thereon.

2741 R. Swift, Hardy-terrace, Hounslow, Middlesex. Improvements in the manufacture of iron kegs and other metal cases.

2742 J. I'Anson, jun., Darlington, Durham. Improvements in locking apparatus for controlling railway switches and signals.

2743 P. J. Kurtz, Rippberg, near Walldurn, Baden. Improvements in chaff cutters.

2744 J. Jacobi, Kladno, Bohemia. An improved proces

for removing phosphates from ores, and for utilising these phosphates.

2745 W. R. Lake, Southampton-buildings, Chancery-lane. Improvements in the spindles and fliers of spinning frames.

2746 A. V. Newton, Chancery-lane. An improvement in the treatment of spirits or alcoholic liquids for the purification of the same, and apparatus therefor, a part of which invention is also applicable to the separation of the lighter from the heavier particles of oils and other liquids.

2747 R. L. Hickes, Liverpool-street, City. Improvements in cartridges.

Dated September 22, 1869.

2748 M. Macleod, Manchester. Improvements in apparatus for sanitary purposes.

2749 J. Windsor, Pulrose Mill, Braddan, Isle of Man. Improvements in desiccating and preserving potatoes.

2750 G. H. Chatwin, Gresham-street, City. Improvements in the manufacture of umbrellas, parasols, and sunshades.

2751 E. Hill, Longton, Staffordshire. Improvements in slide valves.

2752 R. R. Gibbs, Liverpool. Improvements in pumps, vacuum pumps, and blast engines, and in lubricators for the same, which are also applicable to other lubricating purposes.

2753 W. J. Cunningham, New Oxford-street, and A. P. M'Carthy, Bloomsbury, Middlesex. Improvements in obtaining motive power.

2754 J. Tarbuck and T. Burns, Abram, near Wigan, Lancashire. Improvements in the method of pumping water from shafts, pits, or similar places, which method is also applicable for drawing gas from goaves in mines, and for ventilating pits or shafts in course of sinking.

2755 C. L. Light, Richmond, Surrey. Improvements in the construction of tram-rails, in the modes of fastening the same, and in a mode of shifting carriages from one line of rails to another.

2756 W. R. Lake, Southampton-buildings, Chancery-lane. A new method of purifying solutions of sugar and syrups.

2757 W. R. Lake, Southampton-buildings, Chancery-lane. Improvements in sewing machine and other needles.

2758 A. V. Newton, Chancery-lane. Improvements in threshing machines.

2759 H. R. Minns, Stapleton-road, Bristol. Improved mechanism for locking or securely connecting the doors of safes, strong rooms, and other like depositories, to the frames thereof.

2760 E. Hernulewicz, King William-street, City. An improved method of securing the intermediate uprights of all kinds of metal and wood fencing.

Dated September 23, 1869.

2761 W. Black and T. Hawthorn, Gateshead-on-Tyne, Durham. Improvements in locomotive engines and vehicles intended to run on railways and tramways.

2762 D. Witty, Manchester. Improved apparatus for propelling vessels.

2763 R. C. Wallace and D. Crawford, Ardrossan, Ayrshire. Improvements in pumps and mechanism connected therewith, applicable to ships and other purposes.

2764 J. Watson, Govan, Lanarkshire. Improvements in tyres for wheels.

2765 V. Chemery, Sedan, France. Improvements in the construction of apparatus for damping and pressing simultaneously the surface of cloth and felted fabrics previous to finishing.

2766 J. F. R. Badiou and F. Bernard, Paris. An improvement in shoes for horses, mules, or other analogous hoofed animals, and in apparatus for manufacturing such shoes.

2767 W. E. Gedge, Wellington-street, Strand. An improved drying machine with application of central ventilation.

2768 W. J. Turner and H. Yewdall, Bradford, Yorkshire. Improvements in machinery or apparatus for the manufacture of bisulphites, and in the application of the same to bleaching and preparing for dyeing or printing textile fabrics and fibres.

2769 F. Trench, Dublin, and E. C. Warner, Brighton, Sussex. Improvements in horseshoes.

2770 G. A. C. Bremme, Liverpool. Improvements in machinery for untwisting and unlaying threads, yarns, strands, ropes, and other spun and twisted materials, which improvements are applicable to twisting, spinning, and other analogous purposes.

2771 J. M. and J. B. Spence, Manchester. Improvements in the manufacture of disinfectants, applicable also to the preservation of manures.

2772 W. E. Newton, Chancery-lane. Improved apparatus for drying grain and other substances.

2773 J. Mackenzie, Edinburgh. Improvements in weighing machines.

2774 J. B. Spence, Manchester. Improvements in feeding steam boiler and other furnaces with fuel, and in machinery or apparatus connected therewith.

Dated September 24, 1869.

2775 J. Faulkner, Manchester. Improvements in exhausting, drawing, or draining the gas from coal and coal mines.

2776 W. H. Hewett, Great Yarmouth, Norfolk. Improvements in producing characters, inscriptions, devices, and designs on metal surfaces.

2777 B. Hunt, Serle-street, Lincoln's Inn. An improved automatic railway carriage or car brake.

2778 W. Strang, Glasgow. Improvements in apparatus for dressing, and in apparatus for beaming, warps.

2779 R. Collis, Webber-street, Blackfriars-road, Surrey. Improvements in the means of propelling velocipedes, also applicable for other purposes.

2780 J. H. Davis, Fenchurch-street, City. Improvements in ships' compasses.

2781 W. I. Palmer, Reading, Berks. Improvements in the manufacture of paper.

2782 G. L. Morton, Grosvenor Park, Camberwell, Surrey. An improved method of stoppering bottles intended to contain effervescing liquids.

2783 J. T. Greenfield, Pencester-street, Dover, Kent An improved side arm for clearing the chambers and rifling of ordnance.

2784 J. W. Morgan, Edmund-street, Liverpool. Improvements in ships' and mooring anchors.

2785 T. B. Daft, Lorn-road, Brixton, Surrey, E. Axmann, Belsize-road, South Hampstead, Middlesex, and T. W. Willin, Clerkenwell Green, Middlesex. Improvements in watches and other timekeepers.

Dated September 25, 1869.

2786 I. Farrell, Clanbrassil-terrace, Dublin. Improvements in bearings for axles, shafting, and such like.

2787 W. Harper, Bolton, Lancashire. Improvements in machinery or apparatus for suspending fabrics in drying stoves.

2788 J. T. Gaze and J. Hymas, Erith, Kent. Improvements in firebars.

2789 H. A. Bonneville, Sackville-street, Piccadilly. A new and improved Greek firearm.

2790 J. P. Turner, Birmingham. Improvements in buckles or fastenings for braces, belts, bands, and other articles.

2791 J. W. More, Market-street, Finsbury, and J. Norman, Hoxton-square, Middlesex. Improvements in means or apparatus for clipping horses and other animals.

2792 J. Worrall, Manchester, and J. Kershaw, Wadsworth, Halifax. Improved machinery for folding piece goods.

2793 S. G. Archibald, Edinburgh. Improved machinery for carding and twisting or spinning oakum, and for balling the same.

2794 J. C. Cushion, Penrose-street, Walworth, Surrey. Improvements in mill bills or chisels and picks for dressing millstones, marble, and other stone.

2795 J. Stuart, Ropemakers' Fields, Limehouse, Middlesex. Improvements in the treatment of the ores of the metals and their products, and in the manufacture of the oxides of the metals, and of the carbonates of the oxides of the metals, and of the metals themselves, also in the manufacture of soda and its carbonates, and of potass and its carbonates.

2796 G. W. Rendel, Newcastle-upon-Tyne. Improvements in gun carriages and slides.

2797 G. W. Rendel, Newcastle-upon-Tyne. Improvements in breech-loading guns.

Dated September 27, 1869.

2798 T. Hall, J. B. M'Kerrow, and T. R. Shaw, Pendleton, Lancashire. Improved means for effecting the removal or discharge of dye wood from banks or yarns.

2799 C. de Bergue, Strand. Improved mode of, and apparatus for, utilising man's muscular power when employed in driving machinery.

2800 W. Boulderson, Strand. Improvements in coverings for the head.

2801 F. W. Fox and E. Walker, Atlas Ironworks, near Bristol. Improvements in locomotive and other engines, and their steam boilers.

2802 J. Peel, J. Sharp, and J. Walworth, Bradford, Yorkshire. Improvements in looms for weaving.

2803 G. Bennie, Kinning Park, Renfrewshire. Improvements in distilling oils from minerals, and in apparatus therefor.

2804 J. Hastie, Greenock, Renfrewshire. Improvements in applying heat and in obtaining motive power.

2805 R. Harlow, Heaton Norris, Lancashire. Improvements in valves or cocks.

2806 E. O'Brien, Liverpool. An improved self-feeding, discharging, and registering beam balance for weighing grain and other substances.

2807 G. T. Bousfield, Loughborough Park, Brixton, Surrey. Improvements in the manufacture of sized paper.

2808 J. R. Swann, Leith-walk, Edinburgh. Improvements in boiler tubes.

2809 J. R. Wigham, Albany House, Monkstown, Dublin. Improvements in the means and apparatus employed in illuminating buoys, beacons, lighthouses, and other establishments or localities, which improvements are partly applicable to other purposes.

2810 T. R. and T. W. Harding, Leeds. Improvements in leather driving bands, and in machinery employed in the manufacture thereof.

2811 W. E. Newton, Chancery-lane. Improvements in lappet or embroidering looms.

2812 W. Kendall, Newcastle-on-Tyne. Improvements in furnaces.

2813 F. Armstrong, Southampton-buildings, Chancery-lane. Improvements in knitting machines, and in the production of selvages thereby.

NOTICE.—Having received communications from persons residing in the country to the effect that difficulties are occasionally experienced by them in obtaining copies of printed specification from the Patent Office, in consequence of the varying nature of the postage thereon, our readers are informed that upon receipt from them of particulars of the specifications they require, together with a remittance for the cost and approximate postage thereof, we shall be happy to procure and forward such specifications free of all further charge. Sums under Five Shillings may be remitted in postage stamps, for sums above that amount a Post Office Money Order should be sent, payable to ROBERTSON, BROOMAN, and Co., Patent Department, 166, Fleet-street, London, E.C., to whom all communications upon the subject should be addressed.

THE

MEC IANICS' MAGAZINE.

NDON: FRIDAY, OCTOBER 8, 1869.

THE C LD COINAGE CONTROVERSY.

WH THER any practical results will llow the prolonged newspaper dis- cussio: to which Mr. Lowe's remarkable coinag speech has given rise is problematical. One a antage has, however, already arisen from i and that is that public attention has been gely directed to the occult and com- plex, it important, subjects of currency and banki . That those subjects are not under- stood ven by those who have been deemed auth ties upon them is evidenced by the c itradictory conclusions at which they have rrived. When such men as Lord Ove one and Sir John Lubbock dispute witl ach other, and Mr. Hubbard and Dr. Leo Levi disagree, it is not easy for the uni iated to decide as to who is right and wh wrong. That somebody is in error is cer n, and Mr. Lowe is not the Daniel wh judgment is to settle the question.

thout wishing to assume infallibility for ou lves, we venture to re-assert that the pro osition of the Minister to reduce the wei ht of the sovereign was in itself a serious mis ake. At this moment that coin stands pre eminent in all respects. Its rate of fine ess is undoubted, its intrinsic and its non inal value agree, and, artistically speaking, it is an admirable example of British minting. It circulates freely, and, without question, over a very large portion of the civilised world; and even the semi-barbarous but commercial natives of the west coast of Africa recognise the English sovereign as a perfect standard of value. Let it be tampered with in weight or in purity, and faith in the coin, now universal, will quickly vanish. No arbitrary enactment of the Legislature can ever establish an artificial or undue value for a mere token of gold, which the sovereign would become by the "Lowe" process. The coin is now a fair measure or division of the material of which it is a compound. It would not be so then. Existing Acts of Parliament recognise and ordain that the weight and value of the coin must agree, and we commend the following extract from the Coinage Act of 1816 to the notice of the Chancellor of the Exchequer, *i.e.* :—"And be it further enacted that from and after the passing of this Act no person shall by any means, shift, or contrivance whatsoever, receive or pay for any gold coin current within the United Kingdom any more or less in value, benefit, profit, or advantage, than the true lawful value which such gold coin doth, by its denomination, import; nor shall utter or receive any piece or pieces of gold of this realm at any greater or higher rate of value, nor at any less or lower rate of value, than the same shall be current for in payment, according to the rates and values set upon them by law; and that every person who shall offend herein shall be adjudged guilty of a misdemeanour, and being convicted shall suffer imprisonment for six calendar months."

It is plain that those who were responsible for this clause knew that by law 40lb. (troy) of standard gold must be coined into exactly 1869 sovereigns, each weighing 123·2744 grains (as is the case at present), and that the Mint price of the article was (as it now is) £3 17s. 10½d. per oz. They, therefore, manifestly, and very wisely, as we think, ruled that the individual sovereign should form an absolute and exact measure of the substance of which it was made. To attempt an infringement of this wholesome and simple arrangement is to invoke confusion, whilst its consummation would be fraught with the direst mischief. By Mr. Lowe's scheme practically the 40lb. weight of standard gold, instead of yielding only 1869, would be made to produce 1884 sovereigns and a fraction, and yet we are asked to believe that the depreciated pieces will be equally valuable with their full weighted predecessors.

With gold at £3 17s. 10½d. per ounce, indeed, such a change cannot be effected with any chance of success. It is not at all probable that even a West African trader would be long deceived by such a piece of legerdemain. He would inevitably diminish the quantity of ivory or palm oil to be sold for British money in accordance with the diminished value of the pieces of gold paid for those commodities. This principle would become general, and no one would receive a Lowe sovereign for more than its real worth. Thus viewed, the whole question is narrowed and becomes comprehensible. With regard to the point of seignorage, it may be well to offer a few observations, for upon this the Chancellor partially relies. He proposes to deprive every sovereign hereafter struck at the Mint of twopennyworth of gold, and still to call it a pound, but he further wishes to make a charge of twopence to the importer of the metal for every sovereign he receives in ex change for that metal. After these marvellous transactions shall have been effected, Mr. Lowe thinks that the public will have no cause of complaint. He maintains that "the charge made for coining adds as much to the value of the sovereign as the amount of metal (one grain) taken from it tends to diminish its value." Some difficulty will be experienced in inducing ordinary people to put faith in this theory, should they be fortunate enough to comprehend it.

It is not clear to us that anything would be gained by the general public if a seignorage were charged. The Bank of England is the general importer of gold to the Mint, although private individuals may send in parcels of the standard metal—in quantities of not less than £10,000 worth—and receive sovereigns in exchange for them. What advantage would follow from charging the Bank twopence for every sovereign returned in exchange for its ingots is not clear. Neither is its justice apparent. The cost of coining every sovereign produced at the Mint was set down by the late Master at one halfpenny as an average. Mr. Lowe proposes to charge this sum in order to cover the cost of manufacture, and three halfpence additional to pay for the prospective wear and tear of each coin. Is this fair to the Bank or the private importer? The public it is who will use up the coins eventually, and ought not the public treasury to be the disburser of the seignorage? In other words, is it not quite as well, and would it not be rather nearer to strict justice, to vote money year by year for the purpose of carrying on the gold coinage from the national treasury?

The truth is that, from whatever point of view the Minister's plans are regarded, they do not present a satisfactory appearance. It is unfortunate to have to differ with so eminent a statesman as the Chancellor of the Exchequer, but it is an unavoidable contingency in this instance. Some time since it was demonstrated in these columns that the selection of heavy sovereigns from the channels of circulation for the purpose of illicit gain was utterly impracticable, so that here again we are at issue with Mr. Lowe. It may be trusted that a thoroughly practical gentleman will be appointed presently to the Mastership of the Mint, and then the Chancellor will have an adviser at his elbow who will protect him from critics, or, rather, obviate the necessity for adverse criticism, and thus neutralise antagonism.

THE FALMOUTH, GIBRALTAR, AND MALTA SUBMARINE CABLE.

IT is in contemplation to have submarine telegraphic communication between England and Malta complete, about the same time that communication is established between Suez and Bombay by the British Indian Cable. The amount of work required to be done to complete the present cable is very much less than with the British Indian; the length, for example, is about one-third less, and the cable has to be submerged starting from our shores, whilst, on the other hand, the Indian cable has more than a two months' voyage to accomplish before reaching its destination. Although the actual work completed up to the present time is but small, yet, for the above fact, there is no reason why the two works should not be completed simultaneously, giving us then the possession of a submarine route from England to India, and one entirely in our own hand and worked by our own staff. The core of this cable will be of the same dimensions throughout, and of the same type as the Suez-Aden section of the British Indian line. The conductor is seven strand copper, of the weight of 120lb. per nautical mile, and of a mean resistance 11·03 B.A. units, at a temperature of 75deg. Fah. The insulator consists of three coatings of gutta-percha alternating with three coatings of Chatterton's compound, to the weight of 175lb. per nautical mile, making a total weight of core of 295lb. per mile. As usual, the core is to be tested after immersion for twenty-four hours in water at a temperature of 75deg. Fah., and at that temperature it is to give a resistance of not less than 200 millions of B.A. units per nautical mile. The total amount of cable required for the work, including the necessary slack, will be 2,462 nautical miles. This length is required for the following sections:—

Falmouth to Lisbon . . .	872 knots
Lisbon to Gibraltar . .	380 ,,
Gibraltar to Malta . . .	1210 ,,
Total	2,462

For the varieties of deep sea, shallow water, and shore end cables, five varieties or types will be required. Of the shore ends required for the three sections as much as 68 miles will be wanted. This type consists of the core well served with jute yarn, steeped in a solution of cutch or other preservative mixture. The core for each type is the same, the only difference being that according to the size of the cable a little more serving may be required. The served core is sheathed with 10 B.B. galvanised iron wires, each ·375in. in diameter (No. 00 B.W.G.). Around this are applied two servings of jute yarn in opposite directions, each serving being coated with a compound of pitch, tar, and silica. Of the intermediate cable there will be two sizes, one much heavier than the other, and being really a light shore end. Of the former type 412 knots will be made. This type is made of the served core sheathed with 10 B.B. galvanised iron wires ·200in. diameter (No. 6 B.W.G.), and protected with two servings of hemp and silicated compound. The heavier type, intended specially for passing through the Straits of Gibraltar, will be sheathed with 12 B.B. galvanised iron wires, protected with a double serving of hemp and silicated compound; of this type about 51 knots in all will be required.

The deep-sea cable—677 knots—for the Falmouth and Lisbon section will be of the usual deep-sea type. The served core will be sheathed with nine strands of wire and hemp, each wire being of the best galvanised homogeneous iron of the diameter of ·099in. (No. 13 B.W.G.) each wire to be covered with 5 yarns of St. Petersburg or Manilla hemp, each strand being passed through a mixture of pitch, tar, and silica, and with a similar mixture the completed cable is served. The

deep-sea cable for the Lisbon, Gibraltar, Malta sections—1,254 knots—will be of a different type, and consist of the served core sheathed with 16 best galvanised homogeneous iron wires of the diameter of ·099in. (No. 13 B.W.G.) and protected externally with two servings of jute and silicated compound. The total amount of cable required, therefore, according to present arrangements, will be:—

Shore end	68 knots
„ intermediate . .	51 „
Intermediate	412 „
Deep sea 1	677 „
„ 2	1254 „
	2462

The foregoing gives some details of the description of cable to be manufactured, but as the work proceeds and shipping commences we will place before our readers some further information with regard to the engineering details of a work so interesting and so important.

ON THE MANUFACTURE OF PIPES.

A MUCH greater amount of importance attaches to the material of which pipes for the conveyance of water and other liquids for domestic purposes are made than people generally imagine or admit. The pipes conducting the water supply from the mains into our houses are for the most part of lead, and this, of all others, is about the most dangerous material that can be used. Lead-poisoning is now so well known to result from the action of certain waters on the pipes that we need not stay here to insist upon the point. We will merely mention in passing that the fact that water is poisoned by being brought in contact with lead has been known for several thousand years. Vitruvius, who flourished B.C. 46, forbade its use for this reason; whilst Galen, A.D 130, condemned lead pipe for conducting water because of its injurious effects. We therefore proceed first to notice the various materials of which pipes are made, then to point out their respective defects or demerits, and finally to determine the material which should properly be employed for the purpose. Pipes, in general, are made of wood, iron, lead, copper, tin, stone, and pottery ware. To these substances we may add bitumenised paper, which has recently been introduced as a material for the manufacture of pipes, although we have had samples of this ware by us for nearly twenty years. Wooden pipes are the most economical in first cost, but their many drawbacks have long since led to their disuse, except, perhaps, in some very exceptional cases. They are wanting in strength to resist the pressure of fluids, and are liable to decomposition, decay, leakage, and infection by insects. Water, too, lying long in wooden pipes, becomes putrid from the animal and vegetable matter collected in them. Iron pipes are employed as street mains for conducting water, and sometimes for house purposes, but are troublesome from rust, difficult of repairing, and are liable to break at the joints when a settlement takes place in the surrounding soil.

The process of galvanizing iron pipes has met with considerable favour, but, in the main, we think it will be found to injure the tenacity of the iron, rendering it liable to split under pressure or during frost. It has, moreover, been found to corrode rapidly. At page 59 of the Mechanics' Magazine for July 28, 1865, we wrote as follows:—"The question of the best and safest material for the construction of water tanks for ships is being discussed in France. Galvanized iron, it seems, has been employed in the French navy, but this is condemned by M. Roux, the author of a memoir on the subject, who finds zinc in the water kept in such tanks, and in such quantities that he considers the liquid unfit for domestic use. He recommends for the Imperial navy water tanks tinned inside."

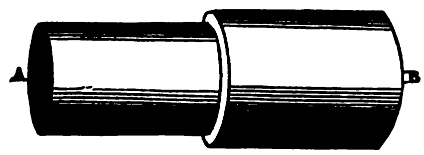
As already observed, lead pipe is commonly used for conducting water from the iron main pipes under the streets into and through buildings. The physical qualities of this pipe admirably adapt it for such use; and in this regard nothing better could be desired. It is easily bent, soldered, and repaired when damaged. These properties have influenced its adoption, notwithstanding a risk popularly understood and admitted, of injurious results to the health of those employing it. With regard to copper pipes, we need only observe that they are rarely employed except in sugar refineries, breweries, and a few other exceptional cases. Tin pipe is employed for beer, soda water, condensing worms of stills in the chemist's and pharmaceutist's laboratories, and occasionally for service pipe in dwelling houses. Stone pipes have been used, and are perfectly safe and wholesome, but difficult to manufacture, and therefore too expensive for use. Pottery ware pipes can only be made in short lengths, are very liable to be broken, and cannot be made to stand a great pressure. It appears, from some ancient buildings, that the Romans sometimes made use of them.

During the past fifty years inventors and manufacturers have bestowed much time and labour upon experiments for making a pipe which would possess the physical qualities of lead, and, at the same time, the chemical properties of tin. These experiments have been induced and stimulated by the advice of chemists and physicians respecting the want of such a pipe, as a substitute for, and to avoid the deleterious effects resulting from the use of, lead pipe. When eminent scientific and professional ability, devoted to the investigation of this subject, testifies to the existence of this evil and to the importance of its correction, it is absurd for individuals to interpose contrary opinions, entirely arbitrary, and based neither upon facts nor intelligence. These opinions are rendered still more absurd in many cases by the efforts they themselves have long been making to accomplish the same object. Among the various plans proposed, one consisted in tinning the ordinary lead pipe inside and outside by drawing it through a bath of molten tin. Another attempt was made to tin lead pipe on the inside by passing it over a hollow mandrel, through which the melted tin was supplied. The method usually employed at present to coat lead pipe is by passing the pipe as it is formed through melted tin held around the pipe above the die for the exterior coating, and supplying it for the interior from a perforated cup in the top of the core or mandrel.

This process forms a thin wash of tin which affords no protection against the lead, as an exposure to the atmosphere destroys in a few weeks all appearance of it, and the friction of water passing through the pipe removes it almost immediately. The process, when applied with the utmost care, is also extremely uncertain in the continuity of its action, often leaving spaces entirely untouched by the tin, and sometimes stopping up the pipe completely by the rapid cooling of the tin held in the cup, which then passes off in a lump, a circumstance not unfrequently discovered only when the water or gas is turned on, and thereby incurring the necessity of taking down the ceiling to remedy the fault. The cost of this pipe is from three to six shillings per cwt. more than the common lead pipe, while it possesses no advantage over it. Lead pipe has also been electro-plated with tin, but this was really no improvement upon the methods previously named. Several other plans have been tried, and more or less practised; but, while some have been attended with such difficulties in the manufacture as to make the pipe expensive, all have been imperfect up to the present time.

Now, however, we appear to have a remedy for the evil complained of in Haines' patent lead-encased block-tin pipe, which is being introduced by the manufacturers, Messrs. Walker, Campbell, and Co., of Liverpool. The pipe manufactured by these improvements differs in many respects from any other of its kind. The encased tin tube is made of any thickness desired, perfectly uniform throughout the whole of the pipe, and in coils of any required length. The two pipes are made simultaneously, and the metals are so thoroughly united at their surfaces of contact that the junction cannot be disturbed, except by the application of heat sufficient to fuse them. In this peculiarity the pipe comports itself as a homogeneous metal, and yet the two metals composing it remain quite distinct in their mechanical and chemical properties. It has all the pliability and other qualities required by plumbers, which, with its great value as a sanitary agent, warrants the recommendation of it for general use. The accompanying figures afford an idea of the character of this pipe. They show the exact thickness and proportions. Fig. 1 represents a specimen of lead-encased block-tin pipe, with a portion of the lead or outer pipe (B) removed, so as to show the tin or inside pipe (A).

Fig. 1.



Figs. 2, 3, 4, and 5 are sections of lead-encased block-tin pipe and lead pipe, tested by hydraulic pressure, and highly spoken of in a report from Mr. A. W. Craven, Chief Engineer of the Croton Aqueduct Department, in the United States. Experiments relating to the strength of these pipes have been repeatedly made, and comprise tests of all sizes in ordinary use. The pipes were subjected by hydraulic pressure to a bursting strain illustrating their comparative strength.

Fig. 2.

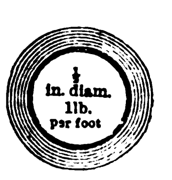


Fig. 3.

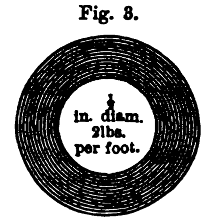
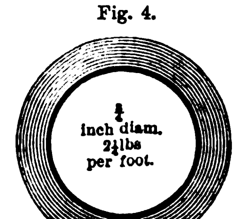


The section shown in fig. 2 burst at 1,650lb. pressure square inch, and that in fig. 3 burst at 1,200lb. pressure square inch.

Fig. 4.



The section shown in fig. 4 burst at 1,325lb, pressure square inch, whilst that shown in

Fig. 5.

fig. 5 burst at 1,150lb. pressure square inch. The heavy black line on the inside of figs. 2 and 4 represents the tin as enclosed by the lead. From a number of testimonials we

have perused it appears that for conducting gas in public and private buildings this pipe is found to be a most admirable substitute for the heavier lead pipe, or the iron tube which is so liable to corrosion. The interior surface is highly polished, and entirely free from flaws or inequalities, and thus presenting no impediment to the flow of water or gas, affords no facility for the accumulation of deposits or tendency to oxidation, which is so frequently the cause of inconvenience or expense in the pipe ordinarily employed for this purpose. With regard to the all important question of cost, as far as we have been able to ascertain there is no difference in price between the new tubing and the ordinary lead pipe. It, therefore, appears a most desirable article, and its superiority in respect of immunity from poisoning leaves no doubt but that it will rapidly come into general favour. It only requires that the public should be made fully aware of the value of the encased tin pipe to ensure that, for domestic purposes at least, none other should be used.

THE ABYSSINIAN WAR MEDALS.

THE Mint is at present engaged, in addition to its ordinary work, in striking 20,000 medals for the troops and others employed in the late Abyssinian campaign. We have been favoured with an inspection of one of these metallic decorations, and unfortunately are not able to speak very favourably of its design. The obverse, of course, comprises the head of Her Majesty as its principal device; this is shown on a plain field, and in profile looking to the left. The portrait is of comparatively small size, but it stands out in very bold relief. The royal brow is encircled by a diadem of rich workmanship, and from beneath which a veil falls in graceful folds down to the shoulder, which is partly represented. Circles of jewels encompass the Queen's neck, and it must be admitted that the features of Her Majesty, allowing a little for idealisation, are faithfully depicted. The bust is placed within an inner ring slightly raised, and engrailed, or dotted, on its inner circumference. On the outside of this ring or frame for the royal picture, a series of nine vandykes are based, their apexes touching the outer ring and protecting edge, which also is finely engrailed. The pyramidal form of the floreated vandykes gives a star-like appearance to the design, and reminds one of the brass medallets of the Virgin Mary, sometimes sold in Roman Catholic churches on the Continent at a nominal charge. In fact, the obverse, as a whole, at the first glance, suggests the idea that its design was borrowed from an original of the class of art treasures just indicated. The legend is very simple, being comprised in the one word—when you can decipher it—"Abyssinia." The letters are placed between the vandykes, and, therefore, at some distance from each other. The first and last letters, "A A," stand immediately over the head of the Queen, and make the points of commencement and termination of the legend dubious. The protecting edge, instead of being broad and bold, is narrow and meagre, and it thus confers an unfinished character on the whole work.

The reverse consists of an admirably executed wreath of laurel leaves, united at the base by a riband, and placed between the protecting edge and an engrailed inner ring. Contrary to the ordinary practice of imprinting the name of the recipient and his rank or title on the edge of the medal, the field or surface of the disc will bear that inscription in the present instance. Thus the warrior's patronymic, &c., will be encompassed by laurels, and made patent to all observers, like the words "one shilling" on a coin of that denomination. The medal is of silver slightly finer than standard, its diameter being 1¼in., its weight ⅞oz., and its intrinsic value 3s. 10½d.! From the diminished size and cost of the medal as compared with those of the Crimean and Indian rewards of valour, it might be supposed that the Chancellor of the Exchequer had interposed and lowered the standard of estimation in which British prowess was once held. It is likely that some two or three months will elapse before the Abyssinian medals are lettered, clasped, ribanded, and made ready for distribution. Every medal has to be twice, or it may be thrice struck between the dies before completion. Medal striking, as compared with the stamping of current coin, is indeed a slow process, whilst the inscribing of individual names and titles on each medal multiplies the labour and consumes much time. Claimants must, therefore, exercise that practical and essential virtue—patience. We must not omit to state that the Messrs. Wyon, of Regent-street, are the artists who designed the medal and engraved the dies for producing it.

LAND SURVEYING.

IF it be true that the art of surveying originated with the ancient Egyptians, consequent upon the effacing action exercised by the periodical inundations of the Nile, one might imagine that the subject must be pretty well exhausted at the present day. This, however, is true only so far as the principles of the art are concerned, which consist in determining an accurate delineation of the horizontal features of the earth. It is evident that the means of accomplishing this result are almost infinite, and will vary with the degree of precision necessary, and the greater or less perfection of the instruments that may be employed for the purpose. While, therefore, on the one hand, the author of a volume on the subject now before us* has to travel a good deal in a well-worn path, it is open to him on the other to strike out a few fresh branches, without actually deviating from the main line. Mr. Smith has availed himself of this opening, and also treats the whole subject in that advanced style of mathematical and geometrical investigation which it is now able to bear. In former times surveyors, as a rule, were not educated men in any sense of the term, and a book similar to the one under notice would not have been appreciated as it deserves to be. At the same time it must not be imagined that the author has plunged into the regions of abstruse mathematics. On the contrary, the formulæ and rules he gives are of a simple and practical nature, and may be easily mastered by anyone possessed of that moderate amount of algebraical knowledge which all professional students acquire as a matter of course. Mr. Smith points out clearly the cases where plain surveying, that is, surveying with the chain only, may be used, and where it is indispensable to have recourse to angular instruments. These, such as sextants, prismatic compasses, and theodolites, are in much greater favour than they were in the early days of the profession. This is owing altogether to the improvement in the education and social status of professional men. It will be easily understood that where a theodolite or other angular instrument is employed a greater degree of skill is required in the observer, and to this must be added a larger amount of mathematical knowledge. Without an acquaintance with the ordinary rules and formulæ of trigonometry, it is impossible to reduce to calculation the observations that may be taken with a theodolite. One of the most useful portions of Mr. Smith's work is that relating to the surveying of submerged districts, which, in fact, is a combination of ordinary surveying and what is nautically termed "sounding." A large number of excellent woodcuts and plates are annexed to the work as illustrations of those parts of the text which need the assistance of such elucidation. The author and the publisher may be alike congratulated upon their successful efforts to produce a volume which will form a valuable aid to all those desirous of learning how to survey and level

* "A Treatise on Land Surveying, in theory and practice, giving the best methods of surveying and levelling, for statistical, estate, and engineering purposes, together with full explanations of the construction, adjustment, and use of theodolites, levels, and other instruments required in the field and office work of surveying and levelling." By JOHN A. SMITH, Civil Engineer. London: LONGMANS, GREEN, and CO. 1869.

TELEGRAPHIC NOTES.

WE last week briefly noted the completion of a line of telegraph from the Land's End to the Scilly Isles; we now append a few further particulars. The credit of originating the undertaking is due to Mr. Buxton, of Scilly, who, since the passing of the Telegraphs Bill through Parliament, has been unremitting in his endeavours to get the Post Office authorities to lay down a wire to the island, but they having declined to take the matter in hand, it was eventually decided that it must be done by a private company. The company was formed and negotiations were entered into with the Post Office, the Board of Trade, and the Duchy of Cornwall, and with Mr. Augustus Smith, lord of the Scilly Isles; and eventually all the powers sought for were obtained, Mr. Smith granting a concession to the company of the exclusive right to lay, maintain, and work the cable for twenty-five years. Mr. Fenwick, of Gateshead, was entrusted with the manufacture of the cable, which is one of the light kind, and is about three-quarters of an inch in diameter. The core consists of three copper wires, insulated by india rubber, the work of the Silvertown Company. The outer covering is composed of six strands of the best Manilla hemp, through each of which there runs a galvanised iron wire. It weighs 17cwt. per mile, and its breaking strain is 3½ tons. The shore ends, for a mile and a half, are bound, in order to protect them from chafing against the rocks, by six strands of charcoal galvanised iron wires, each strand containing seven; and perhaps nowhere is the perfection of the workmanship so clearly visible. Thoroughly compact, the cable at these points is yet admirably flexible. The wire-coating naturally adds materially to the weight of these portions, which, instead of 17cwt. per mile, are four tons. The steamer "Fusilier," which was engaged in the work of laying the wire, and had some few passengers interested in the work on board, on her return to Penzance was received with a salvo of guns. The cable lies between Yawn Reeth, a small cave in Millbay, a mile and a half south of Land's End, and a spot close by Deep Point, beneath the high lands of Normandy, at St. Mary's, one of the Scilly Isles.

The following particulars appear in the "Eastern Budget" relative to the proposed submarine cable between Odessa and Constantinople:—The project is warmly supported by the department of commerce in Odessa, and a company in London has offered to complete the undertaking for £75,000. It is calculated that in order to obtain a return of 5 per cent. on the capital at least 50 dispatches a day, or 18,000 a year, will have to be forwarded The "New Russian Telegraph" says that the laying of this cable will be of the greatest advantage to Southern Russia, as telegrams can now only be forwarded between Odessa and Constantinople *via* Vienna and the Danubian provinces. At the station of Toultcha so many telegrams are received that they are sometimes delayed from two to eight days.

On the 1st inst. the submarine telegraph cable, lately manufactured by Mr. W. T. Henley, of North Woolwich, for connecting Grisselhamm (Sweden) and Nystad (Russia), was successfully laid by him, thereby completing the system of the Great Northern Telegraph Company of Copenhagen. The length of the cable is about 100 nautical miles.

We understand that the post of engineer in the new Department of Post-office Telegraphs will be conferred upon Mr. R. S. Culley, the present engineer of the Electric and International Telegraph Company.

The number of messages which passed over the French Atlantic Telegraph Cable during the week ending October 2, was 775, the cable charge upon the same being £1,710

NOTES ON RECENT DISCOVERIES IN SCIENCE AND THEIR PRACTICAL APPLICATIONS.

AMMONIA EXPLOSIVE—CHLORAL AND ITS EFFECTS—A SCARLET DYE WITH ROSANILINE—IMITATION SILVER—IMPROVED MODE OF REFINING RAPE OIL.

THE "ammonia" powder, some of the effects of which we noticed in our last, excites curiosity from its name, ammonia not being recognised as an explosive. In all likelihood, the ingredient in the composition from which the name is taken is picrate of ammonia. This alone is not a very explosive compound, but when mixed with a nitrate or with a chlorate, it forms a detonating mixture of great power, perhaps of greater power than the mixture of picrate and chlorate of potash which caused the terrible explosion in the Place de Sorbonne. Such a compound may be a little safer than nitro-glycerine, since it would not be liable to spontaneous explosion, and would require greater force to set it off. But the mixture can possess no such advantages as would be likely to make a rival of gunpowder and gun-cotton.

We may notice here an English discovery, of which we learn from the proceedings of the Academy of Science of Paris. The Academy meets every week throughout the year; and though, in all probability, the communication was made simultaneously to our Royal Society, we are not likely to hear of it through this channel until about Christmas. It is true that this particular discovery is of no great importance, but if it had been ever so valuable the same delay would have occurred. Mr. Crace Calvert has found that nitrogen is obtained by the action of hypochlorite of soda on sulphate of ammonia. It ought to be borne in mind that Mr. E. Davey, of Dublin, several years ago, found that nitrogen was liberated by the action of hypochlorite of soda on urea. The reactions in the two cases will be somewhat similar; and the step from the one discovery to the other is not a wide one. As Mr. Davey's discovery enables us to estimate urea very accurately, so Mr. Calvert's process will perhaps be useful to chemists who have to value commercial sulphate of ammonia.

We have mentioned the new anæsthetic, which, however, proves to be no anæsthetic, but a sleep producer of the most gentle and agreeable quality. Chloral is a compound of chlorine, carbon, hydrogen, and oxygen in proportions which lead chemists to assign to it the formula $C^4Cl^3HO_2$. It may be prepared in two or three ways, but the most easy is by distilling together starch or sugar, hydrochloric acid, and peroxide of manganese. This process, although the most simple, is still complicated and troublesome, particularly in the purification of the chloral, which in the end is obtained in the form of a thin oily liquid which assimilates water, and becomes a solid hydrate. The value of the substance is such as will stimulate chemists to endeavour to simplify the mode of production; and we shall soon, no doubt, have chloral at a more reasonable price. As to its effects, it is not necessary to say more than that a few grains, in the course of a quarter of an hour, produces a deep refreshing sleep, lasting for several hours, from which the subject awakes without feeling any discomfort.

Attempts have been made to dye scarlet by means of picric acid and rosaniline, but only with partial success. The picrate of rosaniline precipitated upon the fabric has always a dull, tarnished shade which nobody admires. A beautiful bright scarlet may, however, be obtained by first dyeing a yellow with Persian berries or turmeric, and topping this with rosaniline, a pure colour being employed. The berries, mordanted with tin, alum, and cream of tartar, give the best ground.

Wagner and Winkler give the proportions for a new white alloy, or imitation silver, which takes a beautiful polish and does not readily tarnish. It is composed of 70 parts of copper, 23 parts of nickel, and 7 parts of aluminium.

M. Michaud has improved the mode of refining oils by means of sulphuric acid. As ordinarily employed the acid is poured among the oil, and the two are mixed together by means of an agitator. The admixture is tedious and never very complete. M. Michaud directs the acid upon the oil in very thin streams, and at the same time blows a strong current of air through the oil. In this way a very lively agitation is maintained, and the air carries the "foots" to the top, where it forms a thick scum, which may be skimmed off. The draught of air is then continued as long as a scum forms. After this a jet of steam is sent in, and the oil kept for half an hour at 212deg. Fah.; after which the mixture is allowed to settle and the oil is then run off and filtered. An oil of very superior quality is said to be obtained by this process.

SAFETY OF DR. LIVINGSTONE.

FALMOUTH, OCT. 6, NIGHT.

A MISSIONARY who has landed here to-day from Zanzibar brings important intelligence concerning the safety of Dr. Livingstone. He states that letters had been received at Zanzibar by Dr. Kirk from the great traveller himself, dated Lake Tanganika, February, 1869. At that time Livingstone was well, but short of provisions. He had been deserted by all the Europeans who had accompanied him, and was then living on rice and fruits supplied by Arabs.

THE CHEMICAL FIRE ENGINE.

ON Friday last, a series of experiments were made with Dicks' chemical fire engine, which thoroughly demonstrated its value as a perfect fire extinguisher. This apparatus, as will be seen by the annexed cut, is what is generally

known as "l'extincteur," but the details of which have been improved by Mr. Dicks. The engine is simply a huge soda-water bottle, the contents of which are allowed to escape by opening a valve-cock instead of by withdrawing a cork; in fact, it is a monster gazogene. The cylinder is filled with water, into which is emptied a given quantity of bicarbonate of soda. Tartaric acid to the required extent, in the shape of crystals, is then placed in a perforated tube, which is screwed into the top of the cylinder, and, of course, dips into the alkaline water as seen in the section. The crystals take some time to dissolve, and thus the carbonic acid gas is generated by degrees. In about four hours the apparatus is ready for use. It is, of course, always kept charged, and the inventor has found, on trying one which had been charged for three years and a half, that it was quite as active as those only recently charged. On the outbreak of a fire, the arms of the operator are put through the slings shown on either side of the elevation of the machine, and it is carried on his back. He directs the hose with his right hand whilst he regulates the valve with his left. On the occasion to which we have referred, the agent for the apparatus, Mr. J. Sinclair, of 9B, New Broad-street, City, had prepared a trough, some 10ft. square, which was filled with pitch. Upon this some petroleum was thrown and the whole was ignited. In a few seconds, Mr. Sinclair had extinguished the flaming mass, which was afterwards re-lit and again extinguished as rapidly as before. Afterwards, a structure of inflammable wood, 14ft. long, 9ft. high, and 4ft. thick, composed of barrels, split wood, and shavings, profusely sprinkled with petroleum, was set on fire, and it was allowed to burn fiercely. Two extincteurs were brought to bear upon the burning mass, and the flames were instantly subdued. A quantity of petroleum was again thrown over the structure and allowed to burn up more fiercely than before, this time the fire getting a good hold of the material used, when it was again completely extinguished in about a minute and a quarter by the two machines. The importance of the apparatus in arresting fires at an early stage, and thus preventing large conflagrations, cannot be over-estimated. We are informed that, during the four years that the machine has been before the public, seven hundred fires have been successfully arrested by them, thus saving a vast amount of valuable property, and, it may be, a number of valuable lives. Its proved efficiency is such that no one should be without such a simple and economical means of rapid fire extinction.

THE PROPOSED CHANNEL BRIDGE.

THE arrangements which are being made in Paris for testing M. Boutet's principle of bridge construction are now nearly completed. The final experiments, which will shortly be inaugurated, will be attended by the principal engineers in France; invitations will also be sent to the leading engineers in England. We may, therefore, conclude that its merits and demerits will be thoroughly investigated. The main point to be determined is the solidity of the structure, for in its construction there is really no practical difficulty. The piers will be floated into their required position, then submerged and screwed into the rocks at the bottom of the Channel by means of powerful submarine drills. The upper part of the main structure is to be composed of iron cables, carried across each pier, and united by members of the same material. The spandrels of the arches will form a sort of cross lattice bracing, and will, it is said, add considerably to the support of the whole bridge. The total cost of the bridge will not, it is estimated, exceed £3,000,000, and it is believed that in little more than two years from the date of the commencement of operations the bridge may be got into actual use. When we consider the gigantic engineering works which have been so recently and so successfully carried out, it must certainly be admitted that after all there is nothing so very impracticable in a bridge across the Channel. It is but a multiplication of large spans, the members of which, so far as we have yet seen, are by no means calculated to overstep the limits of safety by the production of injurious strains. It is simply a question of "bigness," such as has been the leading idea of engineers of late in designing roofs for railway stations. Of course storms may and doubtless will interrupt the progress of the work occasionally, and may possibly extend the time of construction beyond that anticipated by M. Boutet. But as yet we can find no valid reason why the Channel should not be bridged. However, we trust the forthcoming experiments will set at rest all doubts and fears as to the correctness of the Boutet system.

MARSDEN'S TUBE JOINT.

THE important improvements in making the joints of pipes tight, and at the same time flexible, which have been effected by Mr. C. Marsden, of 224, Kingsland-road, London, were fully described at page 279 of our last volume. Since then Mr. Marsden has put his invention to practical proof, and by various experiments has satisfactorily demonstrated it to be a perfectly air-tight, water-tight, steam-tight, gas-tight, and withal a flexible, joint. One of the comparative trials was with an ordinary 2-inch gaspipe attached to an hydraulic force pump; there were six screw joints, and a 1-inch tap was used as a blow-cock. The joints all leaked and founted, whilst the flexible joint under the same pressure remained intact, thus proving its efficiency. Mr. Marsden's plan is to have a flange on one end of each length of pipe, upon which circular projections are formed. The opposite end of each length is also made with a protuberance on the exterior, which has circular projections similar to those on the other end. The spaces between the projections are filled in with packing, and the ends of the pipes are brought together, the end of one just fitting into that of the other. The ends are then connected by being enclosed within a socket formed in two parts, which are firmly held together by rings and screws. The inner edge of the end of one pipe is chamfered, and the outer edge of the end of the other is made to fit inside the chamfer, so that a ball and socket action is secured, and the pipes will follow any undulation formed by a settlement in the ground, or arising from any other cause. Mr. Marsden has a hinge joint for steam and fire-

engines, which can be attached in a few seconds, and is, therefore, of the first importance in connection with the saving of life and property from fire.

The simple flexible jointed pipe will follow over or under any inequality of ground, and yet is perfectly air-tight; a joint is put in its proper place in a few minutes, a defective pipe can be easily removed—there is no strain on the joint as there is with rigid joints. When a pipe is wanted to be removed, all that is required to replace another is to knock out the wedges and the two rings will slide off, or press the bolt in the hinge joint, lift the top half-socket, then the pipe can be removed without any breaking of flange either of iron or stoneware. No lead or cement is required, thus a great saving of time is gained. This is a most important sanitary invention, for proprietors of houses have too often experienced the nuisance produced by the escapement from drain pipe joints damping the foundation of houses, saturating the earth with foulness, and sending the effluvia through the house, as well as often causing the foundations to sink. All this can be prevented by using Mr. Marsden's joint in stoneware, for no straight line is required, it will deviate as wanted, and keep a perfect air-tight socket.

For ships, this joint is invaluable for steam pipes, pumps, or other purposes, as it will give to the strain of the vessel without causing any leakage. For connecting locomotive steam engines to tenders it is an important improvement and advantage; in fact, this joint is for a number of purposes of great importance, for the ball and socket can be used as from the castings without grinding in. A tunnel on the same principle, but slightly altered in detail for rivers where the water is from 50ft. to 100ft. wide, instead of fords or bridges, where anchorage is not required, is proposed by Mr. Marsden for vehicles and foot passengers. It could be made in three parts, with two joints 11ft. or 12ft. in diameter, floated on barges and lowered without much difficulty, connecting land to land; a 12ft. diameter would make an 8ft. roadway and 10ft. 6in. high inside; 11ft. diameter, 8ft. road, 9ft. high. Tunnels for railways of any length from one mile to twenty or more, of any diameter, without any screws to get out of order by the vibration of trains passing, are again differently carried out in detail. One end of the pipe is fitted with a series of stepped plates, which are secured in their places by rivets, and the adjoining end of the next pipe is fitted with a bulge. Another series of plates is employed, one end of which is forced under the open end of the stepped plates. They are prevented from falling out by being guided into position by a number of rings, fitted on to the end of the pipe. Another ring is employed on the outside to hold the plates; a portion of this ring is looped or pocketed to enable the plates to be placed in position. When passed through this looped portion, they are made to slide round in succession, so as to meet each other, until the whole diameter of the pipe end is covered. They are then firmly secured in places by keys being driven in between them and the ring; the loop is then filled in with a wedge piece, and thus the whole joint is made sound, flexible, and tight. It will thus be seen that this invention is capable of application to some of the most useful and important purposes of construction.

THE LONDON ASSOCIATION OF FOREMEN ENGINEERS.

A VERY numerously attended meeting of members of this institution was held on Saturday, the 2nd inst., at the City Terminus Hotel. Mr. J. Newton, of the Royal Mint, presided on the occasion. The business of the evening commenced as usual with the election of new associates, and among these was Mr. Yeats, foreman of the foundry in her Majesty's dockyard, Bombay. It was next arranged that the members should pay a collective visit of inspection, on Saturday, the 16th inst., to the Abbey Mills Pumping Station of the Main Drainage Works, for which Mr. Bazalgette had kindly accorded permission.

Mr. Nicholson, of the Blackwall Ironworks, Isle of Dogs, then proceeded to read a paper on "A Continuous Expansion Steam Engine," an invention of his own. After some preliminary remarks, the author went on to say that after Watt had converted the reciprocating motion of the steam engine into a rotary motion his next step was to endeavour to effect economy by cutting off the steam at an earlier part of the stroke, and this plan was now known as the Cornish principle. This was followed by Wolff's arrangement of a double cylinder engine and certain modifications of the same by other engineers. Of the Cornish principle he (Mr. Nicholson) should observe that it was far from being perfect. It ensured the taking of all the useful effect out of the steam, but it produced a motion in an inverse ratio to its expansion, and which was therefore inapplicable for many purposes. Wolff's engine he considered to be decidedly better both as regarded economy and action. The continuous expansion engine he believed would be found superior in all ways to both. It was applicable to marine, stationary, and locomotive purposes, and more especially so to the first named. There was very little difficulty in modifying existing marine engines so as to embody in them the continuous expansion system. He proposed to employ two cylinders in all cases, and sometimes three, or even four. In this class of engine no secondary steam was used, the energy of the steam, so to speak, being eliminated in little more than half a revolution, whilst no cut off valves were needed. The defective link motion was avoided. By this arrangement, too, a better rotary motion was obtained than by any other known means, and a full practical range of expansion ensured the highest degree of economy. In the Wolff's engines the effective working area was equal to the difference of the areas of the two pistons, and if the cylinders were made of the same diameter therefore those engines would be found comparatively useless. In such case the mean pressure on the one piston would be found just equal to the mean resistance on the other. This would not be so with the continuous expansion engine, for if the pistons were made of equal area the result would be found thoroughly satisfactory. By cutting off the steam at five-eighths of the stroke in the first cylinder that cylinder did an ordinary duty, and the residue of the steam was worked up in the second or expansion cylinder, thus producing a smooth motion and a maximum of power with a minimum consumption of fuel. The most practicable and efficient way to expand steam was to terminate the stroke at a pressure that would yet do a little more work and then balance the useless resistance. If this theory were true the continuous expansion engine possessed manifest advantages, because the piston of the first cylinder or cylinders that receives the steam from the boilers were in the most powerful position, and could afford to allow of a higher rate of expansion than could be profitably effected in a single cylinder expansion engine.

The whole of Mr. Nicholson's proposed improvements in the steam engine were made more clear on Saturday by the aid of numerous diagrams, and it was also mentioned that they are embodied in the engines of the steam-tug "Era," now employed on the river Thames. Some rather sharp comments upon the extravagant (as Mr. Nicholson thought) consumption of fuel in ships of the Royal navy and the necessity of checking it brought the paper to a close.

In the lengthened discussion which followed it, Messrs. A. Watkins, Briggs, Irvine, Thorburn, Randall, Ives, Gibbon, and the Chairman took part, Mr. Nicholson replying satisfactorily to some objections raised.

In submitting a vote of thanks to the author of the paper, the Chairman took occasion to say that he, in common, he was sure, with every member of the association, felt gratified in the highest degree to find the Government recognising the eminent services of Mr. Whitworth and Mr. Fairbairn. In the conferring of baronetcies upon those gentlemen, who had risen by their own exertions and merit from humble positions in the mechanical ranks of the community to their present exalted sphere, honour had been reflected upon every engineer and mechanic in the kingdom. He wished, therefore, on behalf of the association as well as on his own account, to give expression to the pleasure and gratification they all felt at the conduct in this instance of Mr. Gladstone, and of the hope they had that Sir Joseph Whitworth and Sir William Fairbairn might long be spared to enjoy their well-earned dignities. These remarks were well received, and the vote of thanks to Mr. Nicholson having been unanimously carried, the proceedings terminated.

AMONG the "things not generally known," is that St. John's Church, Wolverhampton, contains one of the oldest and finest-toned organs in the kingdom. The instrument was built in the reign of Charles II., by Revatus Harris, the Banfield of the seventeenth century. After such a lengthened service it will surprise nobody to learn that the organ needs a "thorough repair."

IMPROVED METHOD OF OBTAINING BENZOLE.

THE gaseous products resulting from the destructive distillation of coal, commonly called coal gas, contain a variable amount of benzole and its homologues, which, as is well known, may partly be separated therefrom by submitting the gas to cold or pressure, or to a treatment with chemical reagents, such as nitric and sulphuric acids, chlorine, and bromine. An improved method of obtaining benzole and its homologues from coal gas has been recently patented in England. It is the invention of Messrs. Caro, Clemm, and Engelhorn, of Mannheim, Baden. It consists in placing coal gas in contact with such substances which act as solvents for the benzole and homologues contained therein, without, at the same time, causing them to undergo any chemical change, and, while it has been found that all known solvents of benzole will effect this purpose, the inventors place coal gas in contact with certain hydrocarbons, such as petroleum, schist, and mineral oils, and the higher boiling varieties of coal tar naphtha, as these hydrocarbons are easily procurable and interfere little, if at all, with the illuminating power of coal gas, and, by mere distillation, the benzole and its homologues may be separately obtained from their solution therein, and the solvent rendered again fit for renewed application.

In those cases in which it is essential not to injure the luminosity of coal gas by depriving it of its benzole, the inventors employ as absorbing agents the higher boiling varieties of coal tar naphtha, the boiling points of which range from 180deg. Centigrade upward, and it has been found that by placing coal gas in contact with such hydrocarbons, they will take up benzole and its homologues from the coal gas while the latter becomes charged with the vapours of the liquid hydrocarbons employed. Although any suitable apparatus may be made use of in order to effect the contact of coal gas with the absorbing agent, the inventors prefer the employment of the common coal gas purifiers or scrubbers. The gas enters at the bottom of the apparatus, and, while ascending, it meets a shower of finely-divided coal tar naphtha, which descends from the top of the scrubber, and at a rate varying (say) from 20 to 40 gallons for every 10,000 cubic feet of gas traversing the apparatus. This operation is effected after the final purification of the coal gas and immediately before its passage to the gas holders. The liquid hydrocarbon which arrives at the bottom of the apparatus charged with benzole is drawn into a still, which is heated to a temperature of about 130deg. Centigrade. The distillate or hydrocarbon obtained by this distillation, which generally amounts to 10 or 15 per cent. of the whole liquid, contains chiefly benzole and toluole, which formerly were diffused in the coal gas, while the residue in the still is again transferred to the scrubber for renewed application.

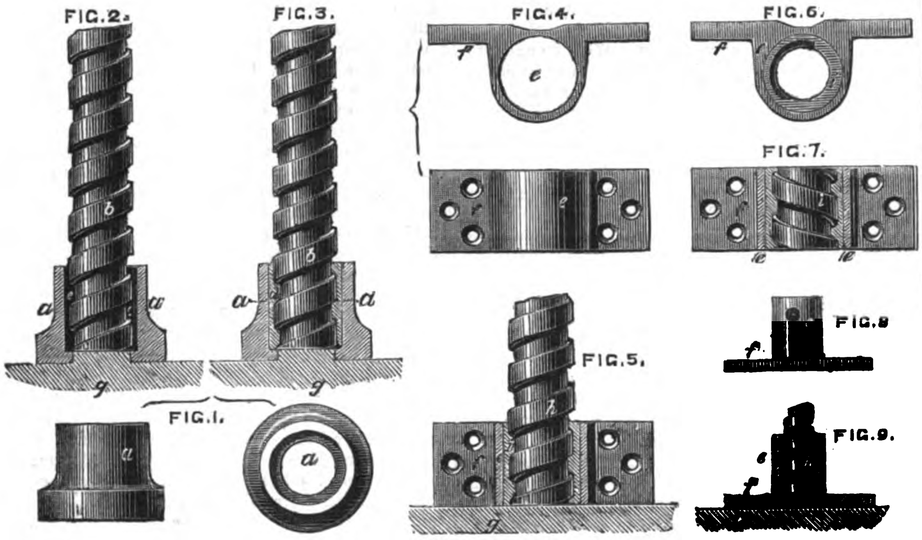
SCIENCE INSTRUCTION FOR WOMEN.

AN important experiment is about to be tried at the South Kensington Museum to promote the instruction of women in science. By permission of the Lord President, Professors Huxley, Guthrie, and Oliver are about to commence a course of lectures on natural science, beginning in November. The fees will not exceed a shilling a lecture, with voluntary examinations, and the terms will even be lower to schools and governesses. The Duchess of St. Albans, Mary Marchioness of Salisbury, the Countesses of Tankerville, De Grey, and Granville, Lady Northcote, and many other ladies have expressed their willingness to assist this experiment. The Hon. and Rev. F. Byng, of Onslow-gardens, London, S.W., is the treasurer and secretary.

DR. CARL BRUHNS, the director of the Berlin Astronomical Observatory, proposes to edit a scientific life of Alexander Von Humboldt, to which the greatest German men of science have promised to contribute. It will be divided into two parts. The first will contain his life in the common acceptation of the word, which has been entrusted to the care of Dr. R. Ave Lallemant, who will have access to a large number of documents and unpublished MSS. The second part will treat of Humboldt's scientific discoveries and investigations. It will be divided into eight chapters, each treating a single science, and committed to the charge of a man of great eminence in that branch. Those who are in possession of unpublished information as to the life or studies of Humboldt are requested to forward it to Dr. Bruhns. The work will be published by F. A. Brockhaus, of Leipsic.

SCREW BOXES OF TABLE EXPANDERS.

BY MR. J. FITTER.



MANUFACTURE OF SCREW BOXES OF TABLE EXPANDERS.

THE invention we are about to describe, and which has been patented by Mr. Joseph Fitter, of Birmingham, consists, first, in making the nuts or screw boxes of table expanders of a white metal instead of the brass or gun metal ordinarily employed for that purpose. Nuts or screw boxes made thus are said to work with a very small amount of friction, and to possess great wearing properties. The invention consists, second, in casting the nuts or screw boxes of table expanders on the screws of the table expanders by the use of metal moulds instead of casting them in sand, as is usually practised. This part of the invention is applicable to the manufacture of nuts or screw boxes made of the white metal or of other metals.

The manner in which this part of the invention is carried into effect is illustrated in figs. 1, 2, and 3 of the accompanying engraving. In the metal mould or chill marked *a*, represented in elevation and plan in fig. 1, and vertical section in figs. 2 and 3, is placed the screw of the table expander, or a pattern screw properly supported. The mould is now ready for the casting of the screw nut or box upon the pattern screw, as represented in fig. 2, where the screw supported in the axis of the mould is marked *b*. The fused metal is poured into the annular space *c* between the screw *b* and the inside of the mould, and the screw nut or box is thus cast upon the screw *b*, as represented in fig. 3, where the cast screw nut in the mould is marked *d*. After the metal has solidified, the mould is fixed in a holder, and the screw nut or box *d* upon the screw *b* is forcibly withdrawn from the mould *a*, the taper figure of the inside of the mould permitting of the ready withdrawal of the cast nut therefrom. The screw *b* is then unscrewed from the nut or screw box, when it is ready to be used.

Mr. Fitter's invention consists, third, in making the nuts or screw boxes of table expanders of an outer iron box or frame, within which the acting part of the nut or screw box is cast. The acting part of the nut or screw box is made either of the white metal or of other metal. The inner acting part may be made separately and forced into and pinned in the outer box or frame. By this improvement, great strength in the nuts or screw boxes is secured, together with great economy in their manufacture. Fig. 4 represents in section and plan the outer iron box or frame used in carrying this part of the invention into effect. The frame consists of a cylindrical part or barrel *e* open at both ends, having side plates *f*, by which it is fixed to the crossbar of the table. The acting part of the nut or screw box is cast within the barrel *e* of the frame in the manner represented in section in fig. 5. The box or frame *e f* is supported on a horizontal rail *g* so as to close one end of the barrel *e*. The screw *h* of the table expander is placed in the barrel *e*. The parts being thus arranged, the metal is poured into the space between the screw *h* and barrel *e*, as represented at *i*, fig. 5, thereby forming the acting part of the nut or screw box. After the metal has solidified, the screw *h* is removed by unscrewing it from the cast screw box *i*. The acting part *i* of the screw nut thus cast in the frame is firmly secured therein by means of pins formed by the cast nut, that is, holes are made in the frame, into which the metal runs, and thus fastens the acting part of the nut to the frame. These holes to receive the cast metal are made at the top of the iron frame *e*, fig. 4.

Fig. 6 represents in end elevation, and fig. 7 in horizontal section, a screw nut or box made in the manner described, that is, of an outer iron box or frame *e*, with a cast inner part *i*. Fig. 8 represents in elevation an outer iron box or frame of a different form from that represented in fig. 4, and fig. 9 represents in section the frame and pattern screw placed in position for casting the acting part within the outer box or frame.

The apparatus for supporting and adjusting the screw perpendicularly in the mould consists of a square bar connected with the horizontal platform or table *g* on which the mould is supported. On the upright bar, two or more holders or clamps slide, being fixed at any required height on the bar by set screws. The screw upon which the nut is to be cast is passed into holes made in the front of the clamps. In front of each clamp is a second set screw, which, by being driven home, fixes the screw in its perpendicular position, and holds it steadily while the nut is being cast upon it. After the nut has been cast, by then removing the front set screws, the screw may be withdrawn from the supporting apparatus, and the screw removed from the cast nut and replaced in the apparatus ready for the casting of another nut.

The white metal to which we have referred is composed of 27 parts by weight of lead, 7 parts by weight of tin, and 3 parts by weight of antimony, or thereabouts; the proportions may be varied within considerable limits without material injury to the metal or alloy.

ON THE MONCRIEFF SYSTEM OF WORKING ARTILLERY AS APPLIED TO COAST DEFENCE.*

By Captain Moncrieff.

UNTIL the time of the Crimean war very little and very slow progress had been made in artillery. Cannon were manufactured on nearly the same models, and of the same materials that had been used for 300 years. Before that time, cast iron was not in use, but the forged or bronze guns, although in some cases large, were not what is now considered powerful, and the penetration of their shot was not sufficient to pass through a parapet of earth that is now pierced even by light rifled artillery. The conditions, therefore, under which artillery was worked, and the means provided for protection against its fire, remained much the same as they were in the time of Vauban. Several events during the Crimean campaign confirmed an impression that has always been more or less entertained, that an increase in the power of individual guns produced greater results than could be obtained by a much greater weight of metal, distributed among a larger number of small pieces of artillery. It is not too much to say, that the development of this art has, since 1855, changed the character of war both on land and water. It has established completely the superiority of a few large pieces over a much greater weight of metal in smaller guns. It has given artillery of all classes a range, a penetration, and an accuracy of fire, which throw into the shade the greatest results that had been previously obtained. It has also stimulated the advocates of cast-iron smooth bores to produce guns that might rival the rifled artillery; and yet it is by no means probable that the limit of power, either of large smooth bores or rifled guns, has been arrived at.

When it became apparent that mighty results were to be obtained from improved artillery, a great deal of engineering talent was directed to the subject. Comparatively new appliances, such as the steam hammer, and new methods of working steel, were called to aid in the construction of the new and powerful guns. So much interest, indeed, was taken in the subject, and so much attention absorbed by it, that the conditions which these improvements in artillery themselves imported with them ran some danger of being neglected. The power of artillery became so great, that the ordinary provisions for protection against its fire were rendered useless. Forts that were considered strong twenty years ago would crumble under the shock of modern projectiles, and in some cases would even be too weak to support the guns while they were fired. That service which the new artillery affected most palpably was the navy, and the navy accordingly took the initiative in introducing means calculated to resist the penetration of the new and terrible projectiles. Everyone is more or less conversant with the process that has been going on of covering ships' sides with iron, which has increased in thickness till it really looks as if the process at last would only be limited by a ship's power of flotation. War ships, however, not only protect their sides against shot, but they also carry the heaviest artillery on their decks. This fact could not be overlooked by those who had to construct coast defences, as well as other works against which modern heavy artillery might be used.

I shall not enter into details regarding the successive steps which were taken in England in this direction, as I understand Colonel Jervoise has already done so in this Institution. It is enough to state that great engineering skill has been exercised, and unwearied efforts have been made to meet the new conditions. That skill and these efforts have, with the experiments at Shoeburyness, given us defensive iron structures which are marvels of strength and ingenuity. Unfortunately, they are also marvels of costliness; and there is room to hope that their use will, therefore, be generally confined to such positions on land as can only be protected by such iron structures. This hope is founded on another system, with which my name is connected, and which I am here to explain. Before doing so, I shall point out the dilemma which left military engineers no alternative, and which compelled them to give up in succession the use of earth, concrete, granite, &c., and at last to resort to the most expensive, but the strongest, material—iron.

There are two considerations always to be taken into account in providing the means of using artillery; the one is to place the gun so as to be most formidable to the enemy, and the other is to place it at the same time under as much cover as possible, so that it is not liable to be disabled, nor are the men serving it liable to be destroyed by hostile fire. These two conditions interfere with one another, that is to say, whatever has hitherto been gained in one direction has been lost in the other. Guns, *en barbette*, lack protection; guns in embrasures or in casemates sacrifice, on the other hand, free lateral range, and it is more difficult in their case to see the enemy, and, therefore, to lay the guns in action. The difficulty that presented itself with the introduction of late improvements in artillery was simply that the increased precision and range, coupled with great improvements in the manufacture of large shells and also in small arms, rendered barbette batteries too exposed to be relied on. At the same time, the tremendous penetration and precision of the new artillery rendered the ordinary parapet and embrasures useless.

What was to be done under these circumstances? Protection from direct fire must be got at any price. The first impulse would be to thicken the parapet. This could not, however, be done, as the necessary angle in the cheeks of the embrasures required for training the guns opens

* Read before the Royal Institution.

up a wider aperture, in direct proportion to the thickness of the parapet, making the maximum thickness in practice 30ft. But shot have been known to penetrate more than 30ft. into the earth; and the most important part of the parapet, viz., that near the guns, must always be thin and weak, whatever may be the thickness of the rest. Shells, striking this part, would just meet sufficient resistance to burst them, and would make havoc among the men. Next, granite masonry was thought of; but it proved in some respects worse than earth, and was found practically bad; there was no alternative but to go to iron. This conclusion was reluctantly arrived at, and reluctantly it was acted on. The decisions of committees which investigated all the bearings of the question, the opinions of professional men, and the experiences of the American war, all coincided, and, accordingly, our important coast works were designed to receive iron shields, casemates, and cupolas. Vital positions in England, such as dockyards and arsenals, must be fortified. It would be false economy indeed to use any method of fortification that experience has proved to be insufficient. No savings could justify the erection of works that might prove at once the tomb of their defenders and, perhaps, of the nation's honour. Therefore, the only proper decision was to take that means to meet the difficulty which was at the time considered best and safest. Expense was properly a consideration very secondary in importance to efficiency.

I shall now endeavour to point out the difficulty of the task which lay before the engineer, even after the decision in favour of iron, from the extraordinary advances already spoken of in artillery. There is only one morsel of comfort left for those who have to provide for the requirements of defence, viz., that a form of artillery fire of a very galling nature remains exactly as before, and, indeed, is not much better than it was in the time of Queen Elizabeth. What is alluded to is vertical or mortar fire. There is some consolation, too, in the reflection that the cause of this fire not being much improved is one to a great extent likely to be lasting. Rifled mortars would no doubt lessen deflection to right or left; but as long as gunpowder is affected in strength by the slightest atmospheric or other influence, and still more certainly as long as a slight error in elevation at long ranges will make a large error on the plane of fire, the comparative inaccuracy of vertical fire must continue. To show how little can be done in this way compared with the admirable precision and accuracy of direct fire, I may state that 100 rounds were fired one day last season at Shoeburyness at 800 yards range, with a 13-inch mortar at the row of experimental casemates which cover a good deal of ground. The mortar was laid with spirit levels and all the appliances of the school of gunnery, and yet the 100 rounds were expended without a single hit. If such is the case with a steady platform, and under such exceptionally favourable circumstances, it can easily be seen how uncertain in its effects would practice be from mortar boats, which move with every wave, if directed at an equally small object. During the eleven months' siege of Sebastopol, the French had 242 mortars engaged, which were themselves exposed to vertical fire, and yet not one of these mortars was disabled. It is, indeed, a strange contrast, that while direct fire is getting more powerful, more accurate, and more destructive every year, vertical fire remains much as it was, and can only be relied on to hit a large object, such as a fort, a town, or anything that covers a great deal of ground. Notwithstanding this, it would be a great mistake to despise it as a powerful and galling means of attack.

To return to the difficulties of meeting direct fire in coast defence. It must be borne in mind that batteries intended to engage ships are obliged to meet an enemy who can move his position to that quarter where he is least exposed, who can continue in motion while he is conducting his attack, and who can seek out the most vulnerable face of the landwork to operate upon. In constructing such batteries it is first of all necessary to make them of sufficient strength to resist the guns of ships which are the most powerful that can be made. It is next required that these batteries should be constructed in such a manner that they can direct their fire with rapidity and precision in any direction in which the ships can take up their position. And, lastly, it is required that they should mount guns of sufficient weight and power to be formidable to the heaviest ironclads. In former times, guns *en barbette* were preferred for this purpose, because they met the two first requirements alluded to; that is to say, that from not being confined by embrasures or ports, they were able freely to follow their floating enemy whatever position he might take up, naval fire at that time being neither so correct nor so formidable as to make such batteries unserviceable. The case, however, is now completely changed; for not only have guns been improved but ammunition also, and heavy shells are most destructive. Rear-Admiral Porter, of the United States Navy, in a report on coast defences, says, "Such guns, standing so high up, are just the objects that naval gunners would delight to explode their shrapnell against, and from my experience in naval gunnery, the third shell would kill every man at the gun."

Von Scheliha, in his treatise on coast defences, says, "Guns mounted *en barbette* may always be silenced by an ironclad." This form of battery, therefore, is disposed of. We shall now examine the difficulties connected with the other alternatives. Common masonry batteries have been condemned as worse than useless, as they would only make the ship's fire more destructive than if directed against guns *en barbette*. Next comes the expensive alternative which has been adopted, viz., iron shields, casemates, and turrets. It is most interesting to examine how far this system of iron, the last alternative left, meets the three requirements of coast defence alluded to, and to see what very great difficulties had to be encountered in applying it. The three requirements are thus recapitulated:—First, strength of the battery to resist naval fire, and give sufficient protection to the men; second, power of fighting the guns with accuracy and effect, of following the enemy with ease as he moves, of being able to face him on any side from which he approaches; third, power of using the most formidable guns to advantage.

The first difficulty was to decide the matter of strength. Now, guns are becoming more and more weighty and powerful every day, and, therefore, the strength required to resist them is an unknown quantity. An iron casemate of the present proposed strength costs, according to official returns, with all the battery adjuncts except the gun and carriage, about £5,000 or £6,000 for each gun. A 2-gun turret about £25,000 or £30,000.* If guns of 50 tons are introduced in ships, as is proposed, these defences are at once quite inefficient, and it is not known how strong or how expensive should be the ironworks to replace them. Such questions must be very embarrassing indeed to those who have to decide these matters. Besides protecting the gun and carriage from the enemy's shot, protection must also be given to the men. This is the most serious of all considerations in coast defence, for the following reasons:—

The best experience we have regarding naval attacks on land works is derived from the late American war, in which a great many actions of that kind took place. It would be unwise to ignore this experience, because the increasing power of artillery only gives it more weight. During the whole of that war very few guns were destroyed by the naval fire in earthen batteries. At Fort Wagner only three guns were totally dismounted, although 2,864 shot and shell were fired into it in 48 hours, and the bomb-proofs were hit 1,200 times. 17 siege mortars, several cohorns, and 13 heavy pieces of artillery were incessantly employed. At Fort Fisher the bombardment was opened at the rate of 115 shells per minute, and although the guns were mounted *en barbette*, only two of them were dismounted when the place fell. At Fort Powell a tremendous bombardment from mortars and gun-boats (the most accurate firing being from 15-inch mortars) was maintained from February 22 till March 2, and not a single gun was dismounted. The success of the ships over the forts was gained by demolishing the works, and still oftener by making the service of the guns so dangerous that the men could not work them. Rear-Admiral Porter, United States Navy, in his report on coat defence, states, "The new-fashioned casemates turned out to be no better than the guns *en barbette*. They were perfect slaughter-houses, and were piled up with dead and wounded. Every shell that went through the port holes killed and wounded every man in the close casemate. This proved to me most satisfactorily that guns in casemates were no better protected from shells than those *en barbette*."

With such evidence as this before them, from men who were conversant with all the events of that great war, it was indeed a serious question to decide what was to be done. I myself cannot see how men in an iron casemate are as much exposed as in a barbette battery; but there is no doubt that if the port of the strongest casemate was as large as those referred to by Admiral Porter, it would be open in the same circumstances to the same dangers, as the damage was done by the entrance of shell through the port. The protection a casemate would afford from vertical fire in such a case would be but a poor advantage if more correct and more deadly weapons than the mediæval mortar could still search out at times the exposed point of the casemate and kill every man inside.

(To be continued.)

* The price of a permanent Moncrieff battery, with magazines, &c., including the extra expense of carriages, is from £1,100 to £1,500 for each gun; an iron shield battery from £1,800 to £2,000 per gun; an iron casemate battery from £5,000 to £6,000 per gun; a turret from £12,500 to £15,000 per gun.

TONNAGE AND NAMES OF STEAM VESSELS.

THE following facts relating to steam vessels are made known through an official return. According to that document, it would seem that, down to January 1, 1869, there had been registered at the ports of the United Kingdom 2,916 steam vessels, their aggregate registered tonnage being 904,191 tons, and their gross tonnage 1,341,106 tons. The date of build ranges from 1823 to 1868; the oldest is the "Ann and Jane," of Newcastle, of 27 tons. The list of the names is a loyal list. Three vessels bear the name "Her Majesty," 16 that of "Victoria," and there are 12 "Queens," 4 "British Queens," 11 "Princes of Wales," 7 "Alberts," 8 "Alexandras," and namesakes of other members of the Royal house. There are 2 "Dagmars" and 2 "Denmarks." Our own country finds upon the waters 10 "Albions," 3 "Anglias," an "England," 5 "Cambrias," 10 "Britannias," a "Great Britain," 3 "Caledonias," 7 "Scotias," 5 "Erins," 3 "Hibernias," 3 "St. Patricks," and a "Brian Boroimhe." Then there are 4 "Britons," a "True Briton," a "Scotchman," and an "Irishman." Of birds and beasts and fishes we have 3 "Hawks," a "Sea Hawk," a "Sea Swallow," 7 "Lions," 8 "Tigers," 3 "Camels," 5 "Bulldogs," 4 "Bees," 2 "Ants," 6 "Dolphins." Heroes of sacred and profane stories are represented. There are 10 "Samsons," 5 "Ajaxes," 3 "Apollos," 2 "Catos," 1 "Tubal Cain," besides 3 "Ariels," 4 "Fairies," and 4 "Fairy Queens." Lords and ladies of high and low degree have given their names to our ships; dukes and earls, "Paul Jones" and "Paul Pry," "Anne Smith" and "Susan Gibbs," "Kates" and "Nellys," "Galileo" and "Euclid." There is 1 "Bridegroom," but 2 "Brides;" 1 "Nun," and last, not least, an Irish steamer, "Number One."

FIXING ANILINE COLOURS.

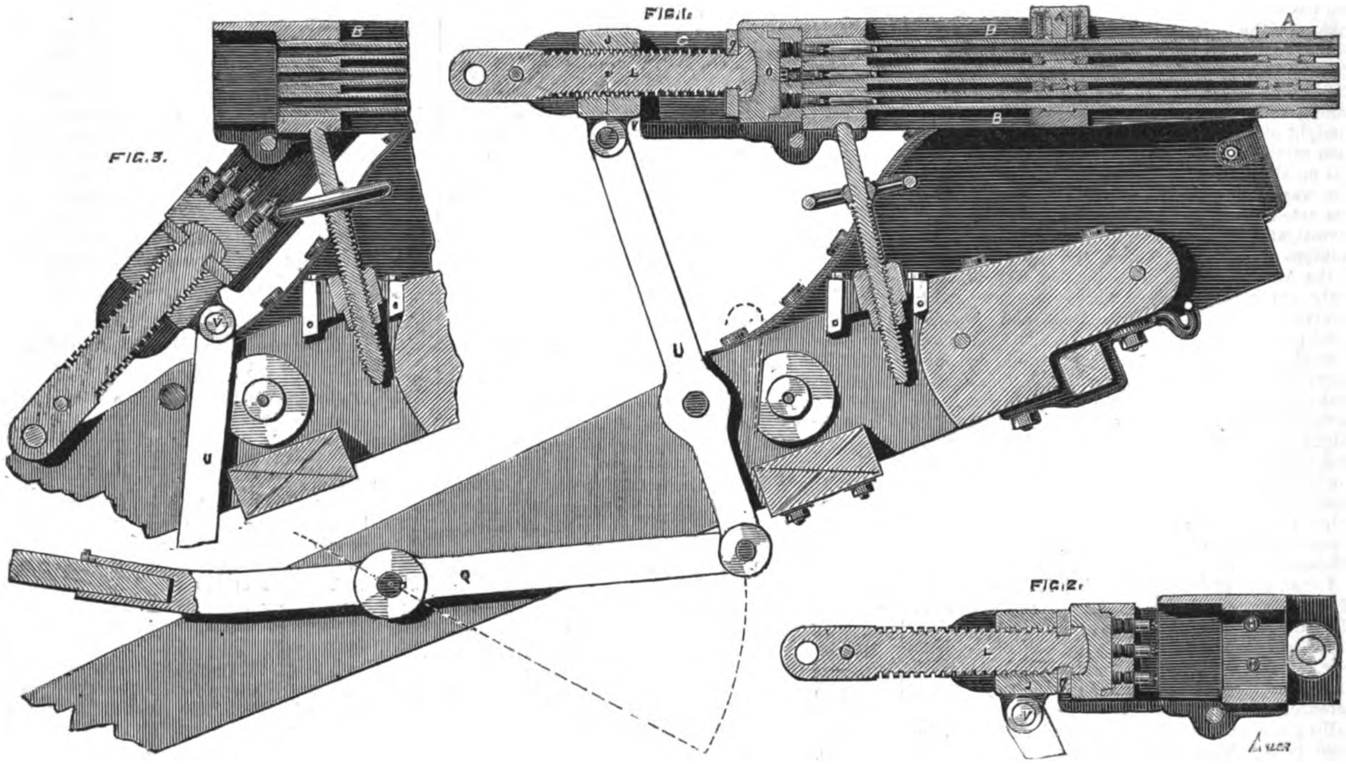
A PASTE for thickening aniline and pigment colours employed in printing woven fabrics, and at the same time fixing the colours and brightening and greatly improving their appearance, has been patented by Mr. Joseph Clayton, of Radcliffe. The paste may be used either as a substitute for or in conjunction with the egg albumen hitherto employed for that purpose, being much less costly, and is composed of water, kid or other glue, turpentine, and blood albumen. We may here remark that when employing this mixture, the operator is enabled to use egg albumen therewith made by beating up both the yolk and the white of the egg together, and thus to effect a considerable economy in this ingredient.

The proportions and method of manufacture which Mr. Clayton has found to answer best in practice are as follows:—First boil 4lb. of kid glue in two and a half gallons of water till dissolved, stirring it well all the time. When boiled down to about two gallons add thereto two gallons of turpentine and boil again; then cool down to about 110deg. Fah., and add four gallons of blood albumen at a strength of about 3lb. per gallon previously dissolved in either water, buttermilk, or blood; mix well and stir for about four hours. To prepare for use take one gallon of the above preparation and mix with it an equal quantity of blood albumen solution (at a strength of about 1½lb. to the gallon), and to this mixture add the aniline or other colour as required.

IT is now finally settled that Lord Napier of Magdala will succeed Sir William Mansfield as Commander-in-Chief in India next year.

THE FRENCH MITRAILLEUSE.

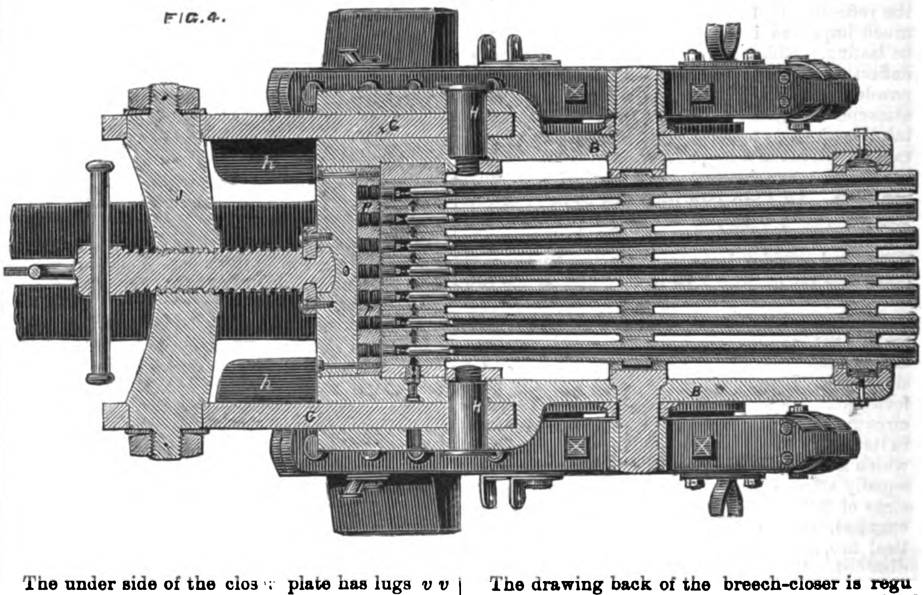
BY M. FRANCOIS J. MANCEAUX.



THE FRENCH MITRAILLEUSE.

OUR readers have been made acquainted through our columns with the principles of the Belgian mitrailleuse; we, therefore, now have much pleasure in placing before them the details of the French mitrailleuse. This important and deadly weapon of warfare is the patented invention of M. Francois Jules Manceaux, of Paris, a gentleman well known for his various improvements in firearms in general, the patent having been secured through Messrs. Robertson, Brooman, and Co., patent agents, of 166, Fleet-street. We may here mention that a mitrailleuse was patented by M. Manceaux in 1867; the present invention, however, is a great improvement upon the former weapon. The first part of the present improvement consists in fitting the barrels between plates which stretch across from one side to the other, and are connected to side plates or straps, which are carried on trunnions. The trunnions enable the apparatus to be mounted upon a carriage, so that it can be used in field operations.

The principle of the French mitrailleuse will be seen from the accompanying engravings, fig. 1 of which is a sectional elevation of the weapon and carriage; fig. 2 is a section of the breech end; fig. 3 is a section of the breech end, with the block or closer drawn down, leaving the barrels free to be loaded; and fig. 4 is a sectional plan, with the cartridges in the barrels and the closer screwed home. This compound gun is composed of a series of barrels, which are fitted between plates A A, which stretch across from one side to the other so as to firmly unite the two side plates B B, upon which the trunnions are formed for supporting the mitrailleuse upon a carriage, so that it can be moved from place to place and employed in field operations. The rear ends of the side plates B B are of greater thickness than the other portions, and are slotted so that the guide plates of the closer can work therein. These plates are centred upon pins, which are kept in position without working loose by means of tappets acting upon the nuts on their ends. The breech-closer plates G extend a distance beyond the rear end of the barrels, and have near their ends long holes, which serve to hold secure a transverse bar J. The central portion of the transverse bar is of larger diameter, or is thicker than the other parts, so that the threaded rod L, which passes through it, may be turned so as to bring the breech-closer nearer to or further from the rear of the barrels. The front of the threaded rod L is rounded, the rounded portion being fitted between two half plates q q.

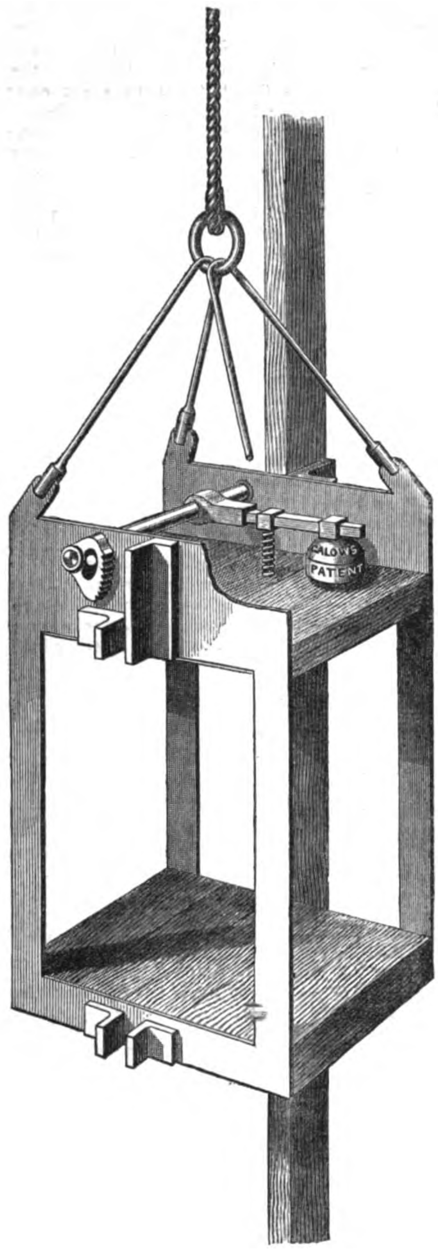


The under side of the closer plate has lugs v v for carrying a pin V, to which the upper end of a link or lever bar U is jointed. The lower end of the link is pinned to a lever Q, so that the closer, when released from the barrels, can be raised and lowered upon their joint pins H H, which are fitted in the side plates B B. The under side of the rear of the side plates has projections for the closer to slide upon as it is being moved, and when it has travelled such a distance as to be tilted, it rests upon a plate h, which forms part of the closer frame G G. The front of the closer or breech block O has a face plate P secured thereto. This plate is provided with a series of holes corresponding to the number of barrels fitted in the frames upon the carriage. The holes are threaded for the reception of screw plugs or nipples, through which pins are fitted. The inner ends of these pins rest upon a disc of horn or other yielding material, so that when the explosion takes place the force of the recoil is diminished. The distance the pins may project is regulated by a washer or plug screwed into the back of the plate P. Under the rear of the breech end of the barrels is attached one end of an elevating screw, by which the depression or elevation of the barrels is governed. The lower end of the screw works in a block or socket on the carriage.

The drawing back of the breech-closer is regulated by the hand lever Q, and it can be retained at the required point by means of a pawl working in the teeth of a ratchet wheel fitted on the side of the frame. When the barrels are filled or loaded with cartridges, and the breech-closer brought in contact with the rear of the barrels by means of the lever handle, the fire can be communicated by means of a percussion cap or fuse or quickfire at one side of the barrel framing, which fire is instantly forced through a hole, and impinges against the cartridge case with sufficient impulse to break it and explode the powder therein. The explosion in the barrel causes fire to be driven through another hole, which leads from the first barrel to the second, and this causes the second charge to be fired in the same manner as the first, and from the second to the third barrel in succession until the whole of the barrels on that level have been discharged. The fire then passes up to a second series of barrels, placed above the lower series in succession, and in a similar manner to a third series of barrels. If the frame has three series of barrels placed in it as is represented in our engravings, M. Manceaux uses a special cartridge for his mitrailleuse, particulars of which will appear in a future number.

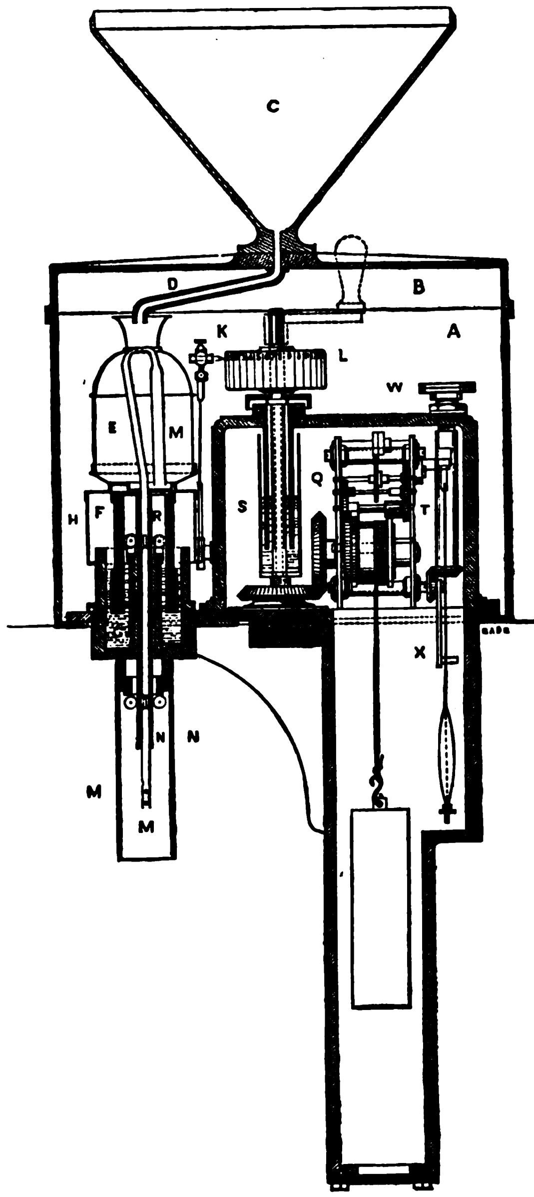
SAFETY HOIST APPARATUS.

BY MR. CALOW.



SELF-RECORDING RAIN GAUGE.

BY MR. ROBERT BECKLEY.



CALOW'S PATENT SAFETY HOIST.

PRACTICAL engineers know that the great objection to safety apparatus for preventing accidents in hoists of mines, &c., hitherto invented has been this—they cannot trust to the old principle of safety cages on account of the terrible amount of friction and destructive action. It is well known that every time the cage descends and ascends the machinery is acted upon four times, which at modern collieries would amount to some thousands of times in a day. Hence the great objection, because they cannot be kept in order without great care and expense. Mr. Calow has, however, through the result of six years' experience, overcome the objection in every way, for, by his arrangement of mechanism, it is not brought into play by the mere slacking of the rope, but when the rope breaks only, the rope not being in any way connected to the apparatus. The motion is obtained in a very simple manner, which constitutes for the apparatus its strong recommendation. Anyone having studied the difference between a falling body and the same body being let down a shaft at the greatest speed it is possible for an engine to accomplish will find a great difference in their respective speeds; it is in the difference in the speeds wherein the motion is obtained, so that the cage has to gravitate before the machine is acted upon. It will be seen from the accompanying illustration that a bar has on it a weighted lever; this weight keeps a spiral spring compressed. When the cage becomes a falling body (*i.e.*, falls at 16ft. in the first second) the support for the spring ceases to exist, and it becomes of a greater length, thrusting the eccentric jaws or grips into the slides, and effectually preventing the cage descending.

This invention was exhibited at the recent meeting of the Iron and Steel Institute at Middlesborough-on-Tees, where it attracted attention. There are already twelve at work at Messrs. Bolckow and Vaughan's works. Messrs. Bell Brothers, another well-known firm in the north, have it to sixteen cages, and the Clay Cross Colliery Company have it to twenty. All have given great satisfaction, and have saved lives and property on more than one occasion. The invention is being introduced into the mining and manufacturing districts by the sole makers, Messrs. Bailey and Co., of the Albion Works, Salford, Lancashire.

SELF-RECORDING RAIN-GAUGE.

By Mr. Robert Beckley.

AT the present time, when the collection of meteorological data has become a matter of such general interest, the need of some apparatus which would record the exact fall of rain is frequently felt, and this instrument has been invented with a view to meet this deficiency. The ordinary rain-gauge, as is well-known, is simply a receiving surface of definite area attached to a reservoir, the amount of water collected being measured at stated intervals. No record is therefore supplied by the instrument of the time in which rain fell, and of the rate of the down-pour. Several attempts have been made by which these would be registered, either by placing a float on the surface of the water collected in the receiver, and attaching it to a pencil, or by receiving the water in what is technically called a tumbling bucket, and employing its oscillation in giving motion to a recording apparatus.

Both these plans are open to serious objections; for, in the first case, the instrument requires to be made with a very open scale if it is desired to record small quantities, and therefore becomes large and cumbersome; while, in the other form of instrument, no fall will be registered unless it is sufficient to fill one of the buckets. Neither of these objections can, it is believed, be urged against the new instrument, which records equally well all falls, either summer showers or heavy storms, and is at the same time small, compact, and self-contained, requiring no special erection, and capable of being placed in a hole in the ground, with the receiving surface barely raised above its level.

The instrument, which was made by Mr. James Hicks, of London, is shown in the accompanying engraving, in which a section is given of the whole. A is a cubical box of thin cast iron, 18in.

square and 12in. deep, furnished with a loosely-fitting hinged cover B. The top of the cover is stiffened by four ribs, which meet at a boss in the centre, into which the funnel C is screwed. The funnel is also of cast iron; but, to prevent rusting, its interior surface, after having been turned, is enamelled. It is provided with a lip 1in. deep to retain the splashes, which is turned exactly to give an area of exposure of 100 square inches. A small aperture in the bottom of the funnel, covered by a strainer, opens into a pipe, D, which conducts the water as it is collected into the copper bottle or receiver E. This is supported by a hollow cylinder F, floating in mercury contained in the annular vessel or cistern G.

As water enters the receiver the float descends in the cistern, displacing more mercury the further it descends; at the same time, the relation between the areas of the cistern and float is so proportioned that the admission of equal quantities of water into the vessel E causes its descent to take place through equal spaces. A cover H, fixed to the top of the float, supports on one side a spring, the upper extremity of which is adapted to hold a pencil K, which presses against a cylinder made of white glazed earthenware, marking on it vertical lines, as the float with the receiver rises and falls.

When the level of the water in the receiver reaches the neck of the vessel, which has then descended to its lowest point, the syphon M comes into play, and, rapidly emptying it, enables it to rise and resume its original position; at the same time the pencil K marks a vertical line from the bottom to the top of the cylinder. As the receiver E has a capacity of 25 cubic inches, this occurs whenever a quarter of an inch of rain has fallen. The syphon M acts on the principle of the intermittent syphon, modified and adapted so as to enable it to act accurately and with certainty in the present case. As the water enters the vessel E, it rises in the short leg M of the syphon, driving the air before it through the long leg $M^{I} M^{II}$; this continues until it reaches the bend at the top, which, being contracted, prevents the passage until a sufficient head of water has accumulated above it to overcome the capillary action; the water then runs down the long leg and brings the syphon into play, which then runs until the vessel is quite emptied (a small depression in the bottom materially assisting it), and the air can enter at the lower extremity of the short leg. The flattened contracted bend of the syphon answers the double purpose of preventing the entrapment of an air bubble in the bend, and also ensuring the emptying of the vessel always occurring immediately the water in it arrives at a constant fixed height; at the same time sufficient area is left not to retard the flow through it.

In order to prevent the retention of a few drops of water in the lower extremity of the tube by capillary action, several small irregular apertures are made in the glass at M^{II}; these, by admitting air, and also allowing the lateral escape of the last few drops, effectually prevent all stoppage of the tube from this cause. The action of the syphon as thus constructed is so certain and constant that it is found on experiment that, if the water running out of the receiver when it is discharging itself be caught in some vessel and returned to the receiver, the syphon will not commence to run until the last drop is poured back, and this may be repeated many times with the same result.

The long leg of the syphon, on issuing from the lower side of the receiver E, passes down a brass tube N N, guided by rollers through the centre of the mercury cistern, so serving to keep float and receiver perfectly vertical and central. In the experimental forms of this instrument, some difficulty was caused by the oxidation of the surface of the mercury in the cistern, preventing the floats moving with sufficient ease and freedom; but a suggestion of Mr. Hicks completely removed this source of annoyance. It consists in pouring a thin layer of fluid glycerine over the surface of the mercury, which, by preserving it from oxidation, and also by acting in a measure as a lubricant, causes the movement of the float to be extremely delicate. The glycerine has also the additional merit of preventing the rusting of the float and cistern.

The registering part of the apparatus consists of a clock Q moving a cylinder L at a uniform rate, a pencil K marking on the cylinder. The pencil is a piece of ordinary black-lead pencil, fixed in a holder, capable of being raised and lowered in an adjusting piece. This piece is fastened to the top of a flat metal spring, which terminates below in a brass bar screwed to the cistern cap, and running up and down between two friction rollers R to destroy any lateral movement. The cylinder L is, as before mentioned, formed of white glazed porcelain, and fits easily on the clock spindle, but capable of being fixed in any position on it. The cylinder is divided by lines marked on it into twenty-four hour spaces, and the traces made on it by the pencil can be easily removed by washing. Two or more cylinders are supplied with each instrument, so that every morning one cylinder can be substituted for another, and the preceding day's record either copied on tracing paper or tabulated at leisure.

The clock Q is contained in a hermetically-closed case, the two places where communication takes place between the interior and exterior being guarded by mercurial stuffing-boxes S and T. S is the vertical axis, supporting and giving motion to the cylinder, being driven round by the clock once every day. By means of a peculiar adaptation of the wheelwork of the clock, a reversal of this motion winds up the clock, a handle (shown by dotted lines in the figure) being temporarily fitted on to the end of it, which is made square for that purpose. The upper bearing of this axle is formed of a tube which surrounds it loosely for the greater part of its length. This tube is again contained within a larger tube, closed at its lower extremity, and fastened to the axis. Mercury is then poured into the tube, half filling it, and so preventing the passage of air either into or out of the clock case, but allowing of its expansion under varying changes of temperature, whilst, at the same time, freedom from friction of the axle in its bearings is retained.

A similar arrangement at T serves to put the pendulum in motion. On turning the milled head W on the exterior of the case, movement is imparted by bevelled wheels to a small arm X, which, pressing against the pendulum rod, forces it out of its vertical position. Immediately the pressure is removed from the head W, the arm X falls back to its original position by its own weight, leaving the pendulum vibrating freely. The clock case is recessed at the bottom to a sufficient depth to allow of the weight falling freely for one day. The clock mechanism can readily be altered so as to go any number of days, and the time scale can be made to any desired length; but, in the present instrument, the scale adopted is that chosen by the Meteorological Committee for their self-recording instruments.

One of these instruments has been at work during the past fortnight, its action, Mr. Beckley informs us, being in every way satisfactory. It records less than 1-100th of an inch fall, with a receiving surface of 100 square inches area, a delicacy, we imagine, quite sufficient for all but the most exceptional requirements.

COPPER AN ANTIDOTE AGAINST CHOLERA.

M. DUMAS recently laid before the Academy of Sciences an analysis of Dr. Burg's report on the preservation from cholera of men engaged in working with copper. He said, in effect, statistics clearly prove that wherever the manipulation of copper was carried on the men engaged in it have almost invariably escaped harmless. The investigations into the subject were conducted under the supervision and control of the commissaires of police, and may, therefore, be implicitly relied on. The number of men who died of the epidemic in 1865 was eight, three of whom were engravers. one optician, one polisher, or burnisher, and one turner. In 1866 the mortality among them from the same cause was exactly the same. According to M. Burg, several of these deaths appeared to result from exceptional circumstances; they were either out of work or under bad sanitary conditions. To enable it to be clearly understood what proportion these numbers bore to the great body of workmen engaged in copper works, it must be stated that the census of 1866 showed that there were in the department in which Paris is situate 122,838 workers in metal, and it is putting it below the mark to say that of this number at least one-fourth—that is to say nearly 31,000—are engaged in working copper in some form or another. Deducting boys under 12 years of age employed in the same work, there remained upwards of 26,000 adults really workmen, consequently the number of deaths in the years specified was in the proportion of 3 to every 10,000. Further inquiries were made with the view of ascertaining if the preservation varied in accordance with the degree in which the metal was handled by the operatives, it being evident that if copper possessed the preservative properties attributed to it this would be manifested in the case of the workmen who died. The result of this branch of the inquiry, it is said, proved the correctness of the theory.

Among gold and silversmiths and watchmakers, the total number of whom was 11,500, there were 16 cases, and there died 1 of every 719 employed. Among makers of metallic spectacle frames, engravers on copper, men engaged in plating copper, polishers, rollers, and coiners, the total of whom was 6,000, there were six cases, the mortality being 1 in 1,000. Among founders, tap-makers, lamp-makers, workers in bronze, sham jewellery, and copper utensils, the number of whom was 14,000, there were seven cases; the mortality was 1 in 2,000. Among opticians, makers of mathematical instruments, dry polishers, stampers, turners, and musical instrument makers, the number of whom was 5,650, there was no case at all. Thus the rate of mortality diminished in proportion as the workmen were more exclusively employed in the manipulation of copper. In other manufactures the mortality was from 10 to 40 times greater. Further testimony in favour of the preservative action of copper was supplied by the society known as the Bon Accord, which was founded in 1819, and entirely composed of workers in bronze, and the medical registers of which are thoroughly well kept. During the whole of the five visitations of cholera, this society, the members of which were scattered in quarters where the epidemic raged with the greatest virulence, had not only not had a single death, but had been called upon to pay only for 106 days of sickness, divided among ten members of the society. Facts supporting the theory were also supplied from other sources. The conclusion drawn from this statement was that if further inquiries established the truth of the theory exceedingly valuable results from a hygienic point of view would follow.

OVERHEATING OF FURNACE CROWNS AND OTHER BOILER PLATES WHEN COVERED WITH WATER.

By Mr. L. E. Fletcher.

(Concluded from page 248.)

THE seventh case was met with near Carlisle, in July, 1868. The boilers, in this instance, which were of the ordinary Lancashire type, and strengthened at the ring seams of rivets in the furnaces with T-iron hoops, drove a condensing engine, and were fed from the hot well. The length of these boilers was about 30ft., their diameter in the shells 7ft., and in the furnace tubes 2ft. 8in., while the load on the safety-valve was about 50lb. per square inch. These boilers gave way as in the previous cases at the furnace crowns, in consequence of which the owners reflected on the makers, and the makers, knowing they had delivered sound work, could only account for the failure by supposing that the boilers had been neglected, and the water supply allowed to run short. On making an examination I found that the deposit within the boilers was of a fine floury nature, like that already described in the previous instances, though the quantity was not so great, neither were the furnaces so severely distressed. The following is an analysis:—

Carbonate of lime	69·39
Iron (per oxide)	2·17
Alumina	2·03
Sulphate of lime	2·39
Carbonate of magnesia	8·38
Silica and sand	10·78
* Organic matter	7·56
Moisture	2·35
	100·00

* Containing 2·95 of fatty matter.

From the above analysis it will be seen that the feed water was very similar to that met with in the other cases previously referred to, though it will be seen that the percentage of carbonate of lime is scarcely so high, which possibly explains the fact stated above, that the furnace crowns were less distressed than usual.

The eighth case that may be referred to was met with in August, 1868, and occurred to a couple of boilers laid down near the River Mersey, in the neighbourhood of Widnes. These boilers were of the ordinary Lancashire type, and were but just new, yet they had failed repeatedly at the ring seams of rivets of the furnace crowns, when the old rivets had been cut out, the holes rimered, and new rivets inserted, but without success.

Under these circumstances the maker of the boilers called upon me, when, in answer to inquiries, it appeared that the feed water was heated by the exhaust steam from the donkey engine, and that the deposit was of a light floury character. I at once recommended that the exhaust should be diverted from the feed water, and on this being done the difficulty with the furnace crowns was overcome

In about a month afterwards the boilers were reported as working satisfactorily, although they had never stood for more than forty-eight hours before.

The following is an analysis of the sediment, which, as in the previous cases, shows a predominating proportion of carbonate of lime:—

Carbonate of lime and magnesia . . .	83·33
Sulphate of lime	1·17
Alumina and iron	4·25
Silica	7·40
Oily matter	0·25
Organic matter	3·60
	100·00

It may be added that further cases have been met with in the neighbourhood of Widnes, and that in December last two other boilers came under my attention, the furnaces of which were bulged out of shape from the same cause as that referred to above.

It is worthy of note that three different cases of injury to furnace crowns from this fine floury deposit have been met with in the neighbourhood of the Mersey, and within a few miles of Liverpool.

I have gone into this subject at some length, because it is one not generally understood. It will be seen that the cases of injury referred to were not confined to any peculiar locality, but were met with in the neighbourhoods of London, Lancaster, Carlisle, Birkenhead, Sunderland, Ruabon, Widnes, and Manchester, so that they were widely scattered over the country. It can scarcely be doubted that for the want of understanding this subject many cases of misapprehension between boiler owners and boiler makers must have occurred, and the blame of leakage at the seams of rivets in the furnaces attributed to defective workmanship, or overheating through neglect of the attendants, instead of to the feed water. It is trusted that the general diffusion of information on this subject will prove of practical value to boiler makers and boiler users, and that the number of examples given will be considered sufficient to establish the fact that in both externally and internally-fired boilers, the plates over the fire may be overheated and bulged out of shape even when covered with water.

Since the above was in print, other cases of injury to furnace crowns have been met with, which strikingly corroborate the views given above, and as they increase the weight of evidence it may be well to refer to them.

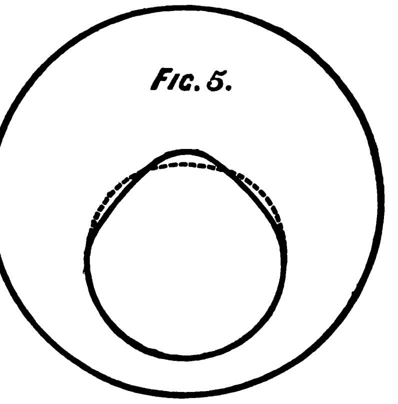
An engineer, who is a corresponding member of this Association, writes from Kirkcaldy that he has met with three cases of the furnace crowns of Cornish boilers becoming overheated, starting at the landings, and getting slightly out of shape in consequence of using waters of certain characteristics, and not from the plates being left bare with the fires burning, or from over pressure of steam. In two of these cases no analysis of the water was taken, but the overheating and flattening of the furnace plates ceased whenever the usual feed was changed for surface water. In the third case it was found on analysis that the water contained 23·63 grains of impurity per gallon, thus:—

22·46 grains of saline matter, principally carbonate of lime, sulphate of lime, and chloride of sodium.
1·17 grains of vegetable organic matter.

23·63

Hardness 14deg. When boiling it quickly begins to leave a deposit, consisting principally of carbonate of lime.

FIG. 5.



The character of the distortions in this case will be best seen on consulting the accompanying cut, fig. 5, which shows that the flattening is at the sides of the furnace rather than at the top, and thus at the haunches of the arch rather than at the crown, while the latter, instead of being depressed, is thrown up. Though it is difficult to establish any precise rule, it may be stated that this is a very general type in the early stages of distortion caused by this description of feed water, though the furnaces soon loose this shape as their distortion increases, and the depression of one side soon preponderates over that of the other, and obliterates it altogether. An illustration of this will be found in fig. 7, on reference to which it will be seen that the right hand furnace just commencing to yield has flattened at both sides at the haunches, while in the other furnace the distortion on the right hand side has completely overwhelmed that on the left. Also in fig. No. 8 a nipping together of the sides and an uplifting of the crowns will be observed.

It will thus be seen that there is a good deal of similarity between the behaviour of the furnaces illustrated in fig. 5 and fig. 7, while the cases of distortion of furnace crowns, owing to the character of the feed and not to shortness of water, met with in the neighbourhood of Kirkcaldy clearly corroborate the views expressed in the previous part of this report.

Another case which was met with in the neighbourhood of Manchester occurred to a well-made boiler of the Lancashire type, measuring 33ft. in length, 6ft. 6in. diameter in the shell, and 2ft. 6in. in the furnace tubes, which were strengthened at each of the ring seams of rivets with a hoop of T iron, while the thickness of the plate was seven-sixteenths of an inch, and the load upon the safety valve 60lb.

The boiler was found to give trouble at the ring seams of rivets in one of the furnaces, the plates cracking at the rivet holes a few inches above the level of the firegrate. This was an extremely mild case. No bulging of the plates took place, neither were the seams of rivets at the crowns affected, while the injury was entirely confined to a range of a few inches above the firebars.

ON THE MODES OF DETERMINING THE COMPOSITION OF THE SUN AND OTHER HEAVENLY BODIES BY THE SPECTRUM OF LIGHT.*

By PROFESSOR MILLER.

It is only three years since the Council of the British Association wisely adopted the plan of still further connecting themselves with the general public by nominating the chief amongst scientific men to give lectures to working men. Professor Tyndall addressed those at Dundee, Professor Huxley the men of Norwich last year, and Professor Miller was appointed to lecture to the working men of Exeter. Professor Miller, in commencing his lecture, which was a series of experimental illustrations of the modes of determining the composition of the sun and other heavenly bodies by means of the spectrum analysis, gave a general account of the modes by which many minerals and metals testified their presence. He then gave a few ordinary chemical illustrations of the manner with which the old system of tests was applied, and commented on the delicacy with which they could now be conducted, some metals manifesting themselves in such infinitely small quantities as less than a millionth part of a grain. After giving a general idea of the law of vibration of musical notes, which were illustrated on the screen as curves caused by a tuning fork, the learned Professor said that everything, solid and liquid, when white hot gives out a spectrum. They could be converted into vapour, and that vapour told its own tale when the light was decomposed into the banded colours. Several beautiful experiments were then given, the white screen being crossed, after the gas lights were lowered, by a large and beautiful spectrum showing the three primary and the secondary colours. Silver was then vaporised, and its beautiful green lines at once manifested themselves as so many bands crossing the red end. The spectra of copper, iron, and manganese followed, and the green, red, orange, blue, and other coloured bands were equally visible. The spectrum of manganese was especially beautiful and brilliant.

The learned Professor then explained that these coloured bands of light were due to vibration among the particles of the vaporised metals. When solar light was thrown on a screen, he stated that, instead of coloured lines or bands, black or very dark ones made their appearance. They were first noticed by Dr. Wollaston, and afterwards by a German optician, named Frauenhofer, who found them so plentifully that they were named after him. A few years ago, Kirchoff discovered there were several thousands, and actually mapped out their relative places. How was it that in an artificial spectrum produced by the oxy-hydrogen flame there were coloured bands, whilst in the solar spectrum they were all dark? Simply this, that the light of any burning metal when it passed through vapour of the same was absorbed. This was illustrated by first showing the bright yellow spectrum of common salt or chloride of sodium, and then passing the light through a lamp that was filled by sodium vapour. The dark band immediately made its appearance on the screen. Professor Miller then explained the structure of the spectroscope as being simply a telescope through which to look at prisms fixed near the further end. By intensifying the telescopic power, the fine dark or coloured lines could be seen in all their abundance. The photograph of the solar spectrum was then thrown on the screen, and its crowd of varying thin and thick dark lines could be seen traversing its entire length. By passing an electric spark through a prism, alongside with solar light, both the dark and coloured bands could be seen at the same time. This proved that the sun contained certain metals, as iron, copper, manganese, calcium, &c. The glowing body of the sun shone through an exterior atmosphere, wherein were floating vaporised metals, and these absorbed the light, and caused the dark lines in the solar spectrum.

The Professor then showed how the feeble light of the fixed stars could be lengthened into an attenuated line, and this line, when minutely examined, was seen to be crossed by dark lines as in the case of the sun. Hence we could tell what the stars are made of, photographs of the spectra of the stars Aldebaran, Betelgeus, and Sirius were shown, and the metal lines explained. The lecturer then proceeded to notice the nebulæ, remarking that some of them could not be decomposed into groups of stars, but were a sort of cosmical vapour. The spectra of several had been analysed. The photographs of spiral and ring nebulæ were then thrown on the screen, as well as the nebulæ in Andromeda. The distances of these heavenly bodies whose composition could thus be ascertained was immense. The light of the star Sirius, travelling at the rate of 192,000 miles a second, would be twenty-three years in reaching our earth. This was almost nothing to the immense distances of other heavenly bodies. They could not but reflect on the vastness of the Creator's universe, and feel that a common mind had elaborated it all. It made them humble when they contemplated such overwhelming vastness.

* British Association.

EXPERIMENTS WITH CHILIAN COAL.

With a view to ascertain the industrial value of the coal produced in Chili, a series of interesting experiments have been made by Mr. V. Pons, first master mechanic, upon the nature and quality of the coal from the Lota Mines, and from this report, published in "La Houille," it appears that the results obtained were highly satisfactory. This coal is of the carbon-maigre character, of deep grey colour, and its fracture is lamellar, or in regular grains; it but slightly soils the fingers when touched, and lights and burns readily, giving a long white flame; it gives off an abundance of very black smoke, is but very slightly contaminated with pyrites, gives but a small percentage of ash, but produces a considerable quantity of clinker.

The subjoined is a comparative table, showing the results obtained in the experiments:—

Coal.	Mean tension of steam p. cent.	Revolutions per minute.	Consumed per hour.	Ash per cent.
Cardiff and Newcastle	400	65	750	10
Cardiff and Newcastle	95	62	780	13
Patent fuel	95	63	800	12
Cardiff	100	64	715	10
Lota	105	64	1042	6
Lota and one-third Cardiff	100	63	980	7
Lota and one-half Cardiff	100	63	900	6

In the first experiment, Lota coal was used alone the journey being made between Lota and Talcahuana. During the journey of 5½ miles, Lota coal without admixture was the fuel employed, the boilers being disposed as favourably as possible; the tubes were swept, and the fire-boxes cleared of clinker. The trial was made with the greatest care, with the object of comparing, by the performance of the engine, and both as to quantity used and calorific effect, the relative value of Lota coal and that of Cardiff, usually employed. With regard to the quantity of fuel used, it greatly exceeded the quantity usually considered as the limit for obtaining the same result; but at the commencement of the experiment, before the bars became clinkered, the pressure in the boilers was very well and regularly maintained, which is often a difficult matter, however much care may be employed in stoking, when an inferior quality of coal is employed. As to calorific power, the Lota coal may be placed amongst the non-bituminous coal of good quality, for they were able to produce with it results obtained with coal enjoying a reputation as of superior quality, and for a short time even to surpass those results. The coal, however, has certain objectionable qualities, which Mr. Pons considers should be mentioned—it burns only on the surface of the mass, it gives off a large quantity of gas, forming a long vivid flame, but of short duration, although the residue remains incandescent on the fire-bars; this inconvenience might be, to some extent, obviated by feeding little and often. The quantity of clinker produced is, moreover, considerable, filling the ashpit in a very short time, and quickly covering the bars to a thickness of 2in. or 3in.; it is very friable, breaking with the least touch, and does not agglutinate on the bars, but mixes with the coke, and deteriorates the quality of the coal, through the necessity of frequent raking; and, lastly, the smoke is very abundant, and quickly chokes up the tubes to a considerable extent.

The second experiment was made with a mixture of one-third Cardiff with two-thirds Lota coal, the journey made being from Talcahuano to Valparaiso; and the result showed a sensible improvement. The pressure of steam was maintained without difficulty

PROPOSED PONTOON VESSEL FOR THE CHANNEL PASSAGE.

BY MR. J. H. PARSONS.

FIG. 1.

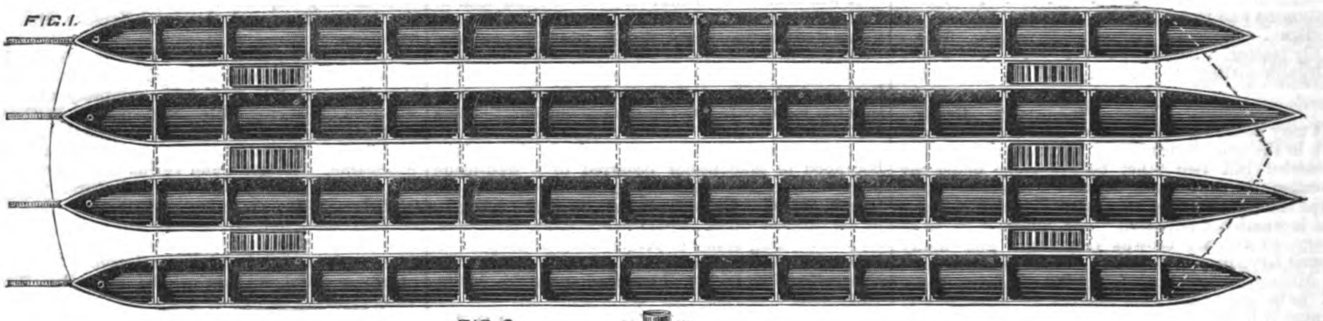


FIG. 2.

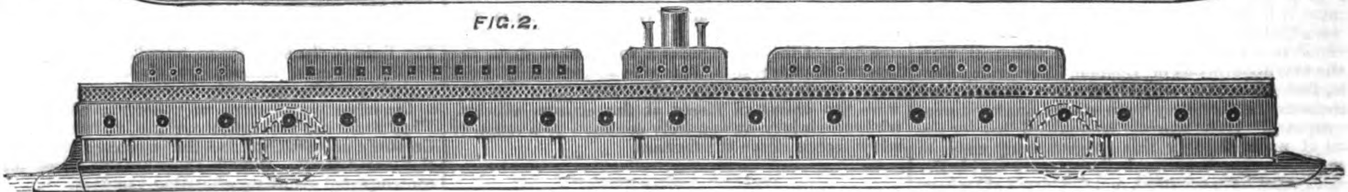

FIG. 3.

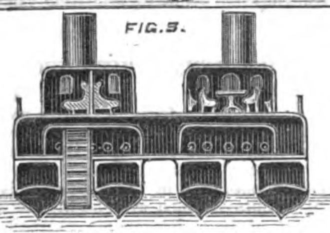

FIG. 4.

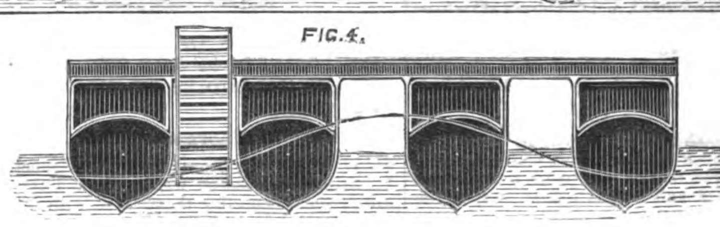

and the choking of the fire-bars was much diminished by the addition of Cardiff coal, but the admixture did not appear materially to diminish the consumption of fuel. In this second trial, the fire was lighted with Lota coal alone, and steam was got up in forty minutes, whilst one hour ten minutes was the shortest time in which they had got up steam from the time the "Megere" left France, which proves that during the combustion of the coal a large amount of caloric is given off. Considering the matter seriously, impartially, and without exaggeration, Mr. Pons considers it good and advantageous for steam navigation. In the last experiment with Lota and Cardiff, half and half, which was likewise made on the journey from Talcahuano to Valparaiso, the improvement was much more decided. The regular production of heat and steam was much more facilitated, and Mr. Pons has remarked that, although the production of clinker was about the same, it was less friable, owing to the combination of bituminous matters from the Cardiff coal, so that it mixed less with the coke, and was more easily removed. Even with this mixture the consumption was still very high, and he attributes it not only to the rapid combustion of the Lota coal, but also to the necessity for frequent raking, which was often necessary twice in a quarter of an hour.—"Mining Journal."

WEEKLY CHEMICAL, MINERAL, AND METAL REPORT.

(From J. Berger Spence & Co.'s Manchester Circular, October 7.)

Chemicals.—There is no feature of importance to relate in the chemical trade of the past week, in its main characteristics the market has not undergone any material change—values are unaltered, and, although production has been considerably lessened, no advance in price is obtainable for immediate consumption. Soda: for soda ash, prices are irregular and remain at £7 to £7 10s. for 48. Crystals at last week's prices, of £4 5s. to £4 7s. 6d. An improved market for caustic at 13s. 6d. Nitrate of soda: stocks remaining very light, nitrate is firm at 17s. Potash: in muriate the demand has fallen off since the close of the month; £7 7s. 6d. to £7 10s. is quoted for 80. Easier prices may be anticipated with the reduction in business. Saltpetre: for Indian 23s. is quoted, and 27s. 6d. for English refined. Transactions have been limited. Alum: the home and export demand keeps pace with production, and prices are not altered. Ammonia: in sulphate there is no falling off in the continental demand; the production having considerably increased, prices are slightly easier for spring delivery, £16 5s. to £16 7s. 6d. being asked for 23 and £13 for 20. Copperas: A more substantial market at 52s. for green and 50s. for dry. Chloride of iron is quoted at 51s. 6d. per ton. Pyrites: maintains previous quotations at 7d. to 8d. per unit; with an increased demand for Spanish. Lime: the sales of phosphate are unimportant, with declining prices, 50s. being asked for 65; bleaching powder is in brisker demand at £8 5s. to £8 15s. Disinfectants in fair request at £5 5s. to £5 15s. per ton. Acids: Tartaric: Foreign quoted at 1s. 2d.; English ground at 1s. 3d. Citric offering at 2s. 5d. Oxalic dull at 7¼d.

Metals.—The past week has been a quiet one in the metal market. At the preliminary meeting of the iron trade, held at Birmingham on Thursday last, it was determined to make no alteration in the present prices of manufactured iron. Iron: Scotch pigs maintain their value, closing at 52s. 9d. to 53s. Cleveland firm, at 43s. for forge, to 48s. for No. 1. Welsh bars, £6 5s. to £6 7s. 6d; Staffordshire, £6 10s. to £7; gas tubes at 60 to 70 off list; boiler tubes, 40 to 45. Copper: nothing of importance has been done in this during the week, and prices are still £73 to £74 for tough ingot, and £68 to £69 for Chili slab. Tin: quiet. Straits £130 to £131; English £125 to £126. Lead: a good business doing in this at £19 to £19 5s. for soft English pig: P. G. brand £18 15s. Spelter: a moderate trade has been doing during the past week, and English is now very firm at £20 15s. to £21 5s.; Silesian, special brands, £20 5s. to £20 10s.; hard spelter for export, £16 5s. to £16 10s.

Correspondence.

THE CHANNEL PASSAGE.

TO THE EDITOR OF THE "MECHANICS' MAGAZINE."

Sir,—I beg to forward you the following proposition for accelerating the route between London and Paris viâ Folkestone, by making the service direct instead of tidal. At the present time, as your readers are aware, there are various schemes afloat for bridging and tunnelling the Channel so as to facilitate the transit to the Continent. It has struck me that the necessity for either of these schemes, which would involve an enormous outlay, would be overcome by carrying out the following:—My idea is to construct a pontoon vessel, as shown in the accompanying sketches, with as shallow a draft as possible, and, by thus rendering it independent of the tide to cross the Bar at Boulogne, to make the service direct instead of tidal as it now is.

If this idea could be carried out, it would be of the greatest public utility, besides being of considerable advantage to the South-Eastern Railway Company, more especially if they could obtain the contract for carrying the Paris mail viâ Folkestone and Boulogne, instead of Dover and Calais as at present. Now the South-Eastern Company carry the mail by special train from London to Dover, and then it is handed over to the London, Chatham, and Dover Company, who have the contract to carry it across the Channel to Calais; it is then passed to the postal authorities, and goes on by train to Paris viâ Boulogne by the Chemin de fer du Nord. If my proposal was carried out it would be the means of a great saving of time, irrespective of the prevention of the present interruption of the regular traffic caused by the tidal service. And not only this, but the vessel itself would, I imagine, by distributing the weight and reducing the resistance of the water to a minimum, be so steady and manageable as to mitigate in a great degree that ordeal of sea-sickness, so terrible to most persons, which must be endured in crossing the Channel in the little packet-boats in use at the present time. This small build is necessitated by the construction and small depth of the harbours both at Boulogne and Calais. The voyage across is to my mind much worse than that across the Irish Channel, and that a great deal owing to the size of the boats. I surmise that the use of a vessel such as I propose would greatly conduce to the comfort of people crossing, and make the journey a pleasure instead of an annoyance. Apart from these advantages, I think that the personal convenience of passengers might be much enhanced by dividing the sleeping from the general saloon where sleeping accommodation is required. The amount of available space on such a vessel as I propose would render this easy, as well as allow them to be of the most commodious and even luxurious style and size.

In the drawings which accompany this letter, I have set out the after part of the deck in separate cabins for the captain and officers, and a general saloon and sleeping saloon for first-class passengers. The sleeping saloon could of course be divided for ladies. The fore part of the vessel I propose to lay out on the same plan, with the difference only of a sorting room for post office officials in case of carrying the mails. For vessels generally, when great speed is not an object, the paddle wheels might be fixed in the centre, leaving a large hold fore and aft for merchandise, &c. The present railway and the improvements now going on at the Harbour of Boulogne can be made available for running trains direct to the boat, as at Dover and Holyhead. The speed of such a vessel as I propose would, I imagine, be very great, if desired, on account of the slight resistance of the waves, which would pass through, under, and over the pontoons both laterally and longitudinally. Although I have adapted my idea of a pontoon vessel to the purpose of facilitating the transit across the Channel, it is, I believe, one that can be applied to navigation generally, and especially for tidal harbours and shallow rivers,

on account of its slight resistance to the water and its light draft.

The following is a description of accompanying plan:—Fig. 1 shows proposed pontoon boat, consisting of four pontoons bolted together with cross girders, leaving free access for waterway to paddles between each, and also forming the bottom or floor of engine room. The boilers, coal bunkers, &c., would be placed in the centre of the vessel, and the engines at each end. The weight being thus equally distributed, enables us to use engines fore and aft when speed is required. The present arrangement of the engine rooms is most unhealthy and distressing to the men, and I know of no means by which, under the present plan, the same amount of light, ventilation, and comfort could be obtained as by the proposed pontoon vessel. In the deck arrangements, the present idea is to separate the sleeping from the general saloon, and to leave a clear passage from stem to stern, which would be an advantage in working the vessel, and serve as a promenade for passengers. Fig. 2 shows the elevation of proposed vessel. Fig. 3 shows section of the same through the saloons. Fig. 4 shows the pontoons and waterway between floor of engine room and pontoons, with supposed line of wave passing through.—I am, Sir, yours, &c., J. H. PARSONS.

59, Gray's Inn-road, October 2.

HARDENED WOOD OR "BOIS DURCI."

SIR,—I shall feel much obliged to any of your readers who can give me information as to the manufacture of the composition known in both France and Germany by the above name. Articles such as small reading desks, fancy perforated work, &c., imitation carved oak, are made by this process. Papier mache is also used. Was there not a company started to work this process here? —I am, Sir, yours, &c., S. D. T.

6, Mildmay Park, N., October 2.

HYDROSTATIC STEERING APPARATUS.

SIR,—The letter of your correspondent "Robert Shenton," in your journal of the 17th ult., escaped my attention, or I should have replied immediately with the following statement of the first experiment of my patent hydrostatic steering apparatus. The "Achilles," of 6,000 tons, was steered for four hours by myself with a small wheel in the chart-house on the bridge, at all speeds and on various courses—putting the helm hard down many times during the four hours the experiments were being carried out. The bilge pumps, equal to about a donkey power, kept the ship quite free from water during the whole time, although the admission of water to work my engine was of course very greatly in excess of what would be employed under ordinary circumstances.

Your correspondent, though doubtless a far better mechanic than I can ever pretend to be, must allow me to remind him of this peculiarity in the demands for a ship's steerage. When a large vessel is going full speed, a great power must always be available at the shortest notice, to avoid collisions and alter the course suddenly for various purposes, such as a man falling overboard or other casualty. To ensure this, if no purely mechanical means are used, a number of men must stand at the wheel for hours together, actually employed during that time in moving it only a few spokes, which is easily effected by one of their number. Now, it is clear that if a special steam engine be employed, as proposed by your correspondent, the steam must be always in readiness in the pipes and passages from the boiler, and there must be condensation going on. This was proved in the "Minotaur" and other vessels which have been fitted with steam hydraulics, and there was always found a want of readiness for immediate action. The principal advantages I claim for my apparatus are a constant readiness for immediate action, without expense while lying idle, and requiring no care or attention—which the steam engine cannot dispense with.

In conclusion, let me add, that owing to the pipe leading the water through the bottom of the "Achilles" having been fitted—so as to avoid the magazine—with five right angles in its course to the cylinder, and a mistake in the working drawings, by which the port in the cylinder is only one half of its proper dimensions, the engine is unnecessarily large and slow in its action. Nevertheless, the power attained indicated an average pressure of 600lb. on the square inch, though 150lb. to 200lb. was proved amply sufficient for putting the helm hard down to 35deg. when going at the rate of fourteen knots, the men never being able to attain a greater angle than 24½deg. I am now able to supply a similar engine, capable of doing the same work in a better way with half the expenditure of water, in less than half the time, and at a cost of little more than half of the one now fitted to "Achilles."—I am, Sir, yours, &c.,

E. A. INGLEFIELD, Rear Admiral.

10, Grove End-road, N.W., October 6.

THE ROYAL AGRICULTURAL SHOW AND THE PLOUGH: ITS HISTORY AND ACTION UPON THE SOIL BOTH IN ANCIENT AND MODERN TIMES, AND THE MODIFICATIONS IT HAS UNDERGONE.

LETTER No. II.

SIR,—In comparing the English ploughs with the whole of those used on the Continent, the English is the only one that cuts a solid unbroken furrow. The plough shown in the International Exhibition of '62, in the Foreign Department, had short, deep, concave turn-furrows and a share to cut the whole width of the furrow, which, as a matter of course, would cause the furrow slice to be pitched roughly over on one side, which would break in falling; but the English ploughshare only cuts about two-thirds of what it turns over. Thus, the tearing up the one-third of the furrow slice assists the gentle action of the turn-furrow to lay it on one side unbroken. Now this, on the light soils, requires a pressure roller to break in the hollow under the furrow, and on the stiff soils it leaves it without a crack, and fairly, as we may say, puddles the face of the furrow, and stops the breathing pores of the soil, the very thing that should never be done. The whole of the French and German ploughs are very short in the handle, which makes them very difficult to guide; and, if their wheels and turn-furrows were taken off, they would resemble their own ploughs a thousand years ago. But who shall say, out of all the different shaped ploughs that till the ground, which is the best? The American plough stands alone in form, but its action on the soil is more perfect, breaking the furrow slice to a much greater degree than the English or any other, and its workmanship and mechanical arrangements are perfect.

The "pulveriser plough" (we are now speaking of our own invention, but it will be more as historians than as advocates) consists of three small ploughs on one beam, one acting below the other, cutting the furrow slice (say) 6in. deep into three parts, each plough being furnished with a short deep concave breast. Thus, at one operation, any clean field is made into a good seed bed. The Canadian swing plough reflects great credit on our rising colony. They lay no claim to invention. They have evidently been taken to Canada by emigrants from Scotland and North Wales, where they used that form long before Canada was of any note. These swing ploughs are beautifully made in lines and workmanship, and vie with those of our best English makers.

Having traced the rise of the plough from the earliest periods, we will next direct attention to the action of English ploughs, which will give our letter a practical and useful bearing.

Perhaps there never was a time when the action and principle of ploughs were so much discussed as at the present moment, every new method of treating the soil being looked upon as of the highest importance. It is believed that our great country could feed itself if better implements were used and a deeper and broader area cultivated. We have, in the United Kingdom, about 74,000,000 of acres of land, and only 44,000,000 of acres under cultivation. Now, it takes about 6,000,000 acres of land in foreign countries to grow the edibles we import to make up the home deficiency. But surely we could find 6,000,000 acres in the 30,000,000 that are now lying idle at home if a wiser and more national policy were pursued by what newspaper leaders call our great statesmen. This is what must be done if we would save our labouring population from the appalling pauperism that now hedges it in on every side, and check the export of gold to foreign lands that should be paid to our unemployed poor, and a patriotic parliament could find no nobler field to labour in. The plough is the main implement that tills the land, but its action upon the soil is opposed to high-class farming, and a drawback to agricultural progress, for the two following reasons. First, the plough leaves the furrow solid, which must occupy time and other implements to make a seed bed. Secondly, it leaves the furrow hollow, into which a great portion of the seed falls and dies. This may be called the death well. And of a great portion of that which does grow, the rootlets get into the hollow chamber, the frost nips them, and the plant dies in spring; or, if it grows in summer, the straw is weak, and falls. This is part of the bad effects of the hollow furrow. Good or bad farming is nothing more nor less than a good or bad seed bed.

It is interesting to observe the action of the plough in different counties. The celebrated iron plough makers cut their furrows at an angle of 45, in order to have as much top as possible for the action of the harrow, but they leave the furrow very hollow. The old wood ploughs of Yorkshire and Lincolnshire place their furrows at an angle of 30—a little too flat, but less hollow. The Kent plough turns its furrows quite over on their backs, that they may have no hollow; but, on the stiff soils, it leaves it too flat. In many parts of Wales, the farmers hold it of the highest importance to have a keen top to the furrow, that the harrow may make a good tilth for the seed. And this would be very well if the bottom of the furrow was as good as the top. Unfortunately, this is only a sacrifice of utility to appearance, for the left side of the furrow is cut out 2in. deeper than the right, which leaves the bottom corrugated.

At the Warwick meeting of the Royal Show, the farmers and plough makers were startled by a kind of new plough made and exhibited by the Messrs. Hornsby. The novelty consisted in a long convex turn-furrow, as, up to this time, all others had been concave. So great and so sudden a change in the mode of turning the furrow slice created a great sensation; yet the result of the trials gave the first prize to this new convex breast plough. We remember well the conversation on the ground at the time it made its appearance. There was hardly a conflicting opinion expressed, but one and all said that if this convex turn-furrow was right, all the others were wrong; and, when the trial of ploughs took place again at Newcastle four years after, there was not one concave turn-furrow on the trial ground. We do not remember an instance in the history of implement progress where there has been such universal copying. Thus, the convex became a raging fashion for four or five years; but it disappeared as suddenly as it came, and left hardly a trace behind, for at the Leicester and Manchester meetings, all the turn-furrows except one or two were concave again. There were no scientific reasons given for its adoption nor for its rejection. It was a wanton caprice of fashion, from which the mechanical sciences should be quite free.

We will conclude this letter by a few remarks on what were called three new ploughs exhibited for the first time at the Manchester meeting. We will take, first, the one invented by Mr. William Woof, of Bedford, which we think is a step in the right direction. His object is to destroy the hollow furrow and leave a tilth in its place; and to cut off about 2in. at the top of the furrow, to bring the furrow in a forward state for the action of the harrow. We saw this plough in operation, and it accomplished its object in a very perfect manner at one operation. His means of accomplishing this important work was simple. He places, at the back of the plough, a bevel disc wheel; and, in the turn-furrow, a steel disc revolving knife.

The next was a new beam for a plough, the invention of Mr. Cook, of Lincoln. It consisted of angle iron filled up with wood, which prevented the beam of the plough from springing or bending in work, which is so common a defect of the iron plough. This we consider the best plough beam ever produced, as it is lighter and stronger than any other. The other was an invention by a Scotchman, and manufactured by Messrs. Fowler, of Leeds. It consisted of a double plough working on three wheels, the object being to have a rolling friction instead of a dragging; but in this there is nothing new, yet, nevertheless, the plough was giving great satisfaction.

All these different modes of treating the soil by the common plough are but one step on the journey, and the end of the journey is a good seed bed. Now, we hold that implement to be the best which brings the soil the nearest to the seed bed at one operation.—We are, Sir, yours, &c.

F. and C. HANCOCK, Engineers.
Plough and Screw Propeller Works, Dudley,
September 4.

THE Edmunds' case will come on in the Court of Arbitration (Court of Common Pleas, Westminster Hall) on Thursday, the 21st inst., at ten o'clock, and there is now every prospect of this long-protracted litigation, which has subsisted now for nearly six years, being brought to a final determination. The arbitrators are the Hon. G. Denman, Q.C., and Mr. C. Pollock, Q.C.; the umpire, Mr. Manisty, Q.C.

TO CORRESPONDENTS.

THE MECHANICS' MAGAZINE is sent post-free to subscribers of £1 1s. 8d. yearly, or 10s. 10d. half-yearly payable in advance.

All literary communications should be addressed to the Editor of the MECHANICS' MAGAZINE. Letters relating to the advertising and publishing departments should be addressed to the publisher, Mr. R. Smiles, MECHANICS' MAGAZINE Office, 166, Fleet-street, London.

To insure insertion in the following number, advertisements should reach the office not later than 5 o'clock on Thursday evening.

We must absolutely decline attending to any communications unaccompanied by the name and address of the writer, not necessarily for insertion, but as a proof of good faith. ED. M. M.

Naval, Military, and Gunnery Items.

WE, ("Army and Navy Gazette") believe that the fiat will shortly go forth for the disbanding of the Royal Canadian Rifles and the Cape Mounted Riflemen, both of which corps will disappear from the Army List at the commencement of the next financial year.

THE "Thermopylæ," Captain Kemball, owned by Messrs. George Thompson and Co., has arrived off the Lizard in 88 days from Foochow, with new season's tea. This is the quickest passage ever made. The average is 95 to 100 days against the monsoon.

THE maritime insurance companies of Paris, on hearing of the disaster at Bordeaux, immediately opened a subscription for the sufferers. Ten thousand francs have been already collected. There is reason now to believe that the losses will not greatly exceed 3,000,000f.

THE following ships are under orders to return to England from the stations named:—"Argus," 6, paddle sloop, Commander F. W. Hallowes, from the Cape of Good Hope and West Coast of Africa station; "Peterel," 8, screw sloop, Commander the Hon. E. G. L. Cochrane, from the Cape of Good Hope and West Coast of Africa station; "Rodney," 72, screw ship, Captain Algernon C. F. Heneage, from the China station.

A NUMBER of officers and non-commissioned officers from the various brigades of Royal Artillery stationed in the United Kingdom are now pursuing a course of instruction in army signalling at the School of Military Engineering at Chatham, under the direction of Captain R. H. Stodhert, R.E., the instructor in telegraphy at that establishment. A party of these have left Chatham for Sheerness, and at night they exchange signals with parties stationed at Chatham, the lime light being used, and the signals being made on Major Bolton's system.

THE Adjutant-General, Lord William Paulet, by command, has issued the subjoined General Order in reference to the Staff College examinations:—The following campaigns will form the subject of examination in Military History and Geography at the examination for admission to the Staff College, to be held in July, 1879:—1. The operations in East Prussia and Poland from December, 1806, to June, 1807, with the battle of Friedland in detail. 2. The campaign of 1859, with the battle of Solferino in detail. Candidates will be expected to have an accurate knowledge of the geography of the seat of war in both campaigns, with reference more especially to military operations.

Miscellanea.

DR. RUTHERFORD has been appointed Professor of Physiology in King's College, London, in the room of Dr. Beale, who has been appointed to the chair of Pathological Anatomy.

BORDEAUX has been visited with another conflagration. The fire broke out in the shipbuilders' yards near the docks, and destroyed property to the value of a million francs.

THE Bishop of British Columbia received on Sunday last a telegram from Victoria, the capital of the colony, announcing the total destruction by fire of the Anglican Cathedral in that city.

THE number of visitors to the Patent Office Museum, South Kensington, for the week ending October 2, was 4,931. Total number since the opening of the Museum, free daily (May 12, 1858) 1,657,205.

A FIRE, which is believed to be the work of an incendiary, broke out on Monday in the gun-cotton magazine of Messrs. Reed and Rowe, situate near the town of Penrhyn, Cornwall. Forty thousand gun-cotton charges for mines were destroyed, but fortunately were so stowed away that no dangerous explosion occurred, although the fire burned with great fury.

THE autobiography of Flora Macdonald, the preserver of Prince Charles Stuart, will shortly be published in Edinburgh. The MS. has till now been carefully kept in the family record chest. The volume, which is being edited by the last surviving granddaughter of the heroine, will contain some interesting anecdotes hitherto unpublished regarding the memorable escape of the Prince.

THE interest in the All-England Ploughing Matches has very considerably abated since the Howards of Bedford and the Hornsbys of Grantham have ceased to compete at them. These two great firms have for some time declined to send their skilled hands against ordinary local ploughmen, and only enter the lists in England at the great periodical trial of the Royal Agricultural Society, regarded as "The Derby" in the ploughing world.

THE number of visitors to the South Kensington Museum during the week ending October 2, 1869, was—on Monday, Tuesday, and Saturday (free), from 10 a.m. to 10 p.m., 14,197; Meyrick and other galleries, 2,353; on Wednesday, Thursday, and Friday (admission 6d.), from 10 a.m. till 5 p.m., 1,767; Meyrick and other galleries, 133; total, 18,450. Average of corresponding week in former years, 12,709. Total from opening of Museum, 8,848,211.

THE "Montreal Daily News" gives a summary of the gold production of Nova Scotia for the eight years ended December 31 last, this comprising nearly the entire period since the first discovery. The total yield in that interval is stated to have been 160,000oz., valued at £640,000, nearly the whole of which was obtained from quartz. Hence the yearly average has been 20,000oz., worth £80,000. The best year was 1867, when the total reached nearly 30,000oz. The number of miners employed is about 700 or 800.

A NUMBER of influential gentlemen met on Saturday last at Middlesborough-on-Tees, for the purpose of founding an Association of Foremen Engineers and Foremen Ironworkers. The proposition met with general approval. It was felt and admitted that the London Foremen Engineers, by associating for intellectual and material advantage, had been instrumental in dignifying the class to which they belong, and that those of Middlesborough might well follow the example set them. The meeting was adjourned to Saturday, the 9th inst. (to-morrow).

AN important meeting of the Royal Horticultural Society took place on Tuesday afternoon. The principal objects of interest were the fruit and esculent and poisonous fungi, though these were far from being the only objects. The Rev. Mr. Berkeley read a most interesting paper from Dr. Curtis, as to the use of esculent fungi in the United States, where they became an important article of food during the mournful struggle between the Northern and Southern States. The various specimens of edible fungi were cooked and freely partaken of by the large assemblage of persons who thronged the council-room.

M. BRUN, living at Soleilhas, Lower Alps, has sent specimens of what he calls St. Helena wheat to the editor of a provincial newspaper. The description he gives of it is that it has one central ear, and round this spout nine or ten others. It is bearded, and each ear, or rather cluster of ears, growing on one stalk contains from 100 to 120 grains. There is, according to him, a double advantage in growing this grain, that it requires a much less quantity of seed, thin sowing being essential to its proper development, and that the crop greatly exceeds that obtained from ordinary wheat.

SINCE Mount Palatine, at Rome, has become the private property of the Emperor Napoleon, the excavations executed by his Majesty's orders and at his cost have produced most valuable results for archæology and for the history of ancient Rome. The works, ably directed by Chevalier Pietro Rosa, member of the Paris Academy of the Fine Arts, have lately brought to light nearly the whole extent of the Palace of the Cæsars, and a description of them will be included in the supplement which the savant Fabio Gori purposes issuing to his great work on the Palatine edifices.

SEVERAL shocks of earthquake were felt at Santo Gemignano, a town about 25 miles south of Florence, on the 26th ult., and the following days. Each was accompanied with subsultory motion and a loud noise. Two houses were shaken to the ground, and many others, with the museum and the churches of the Madonna and Santo Augustino, seriously damaged, those on the north-western side especially. The shocks were felt less severely at Sienna, Colle, Castelfiorentino, Volterra, Certaldo, and Poggibonsi. The sky was cloudless and the heat almost insupportable.

AT the beginning of 1867, there were 5,110kils. of railway opened in Spain, which, during the previous year, carried 10,962,866 passengers. The net receipts of these lines, in 1866, amounted to 143,814,402 reals (£1,498,066). 1,887kils. of railway, in addition to the above-mentioned 5,110kils., are to be opened by the end of 1867, making a total of 6,977kils. The total cost of this network will, when complete, amount to 607,848,512 escudi (£65,850,255), towards which the government give subventions to the amount of 183,228,815 escudi (£19,849,735).

FOUR more statues of the Kings and Queens of England have within the last few days been placed in their respective niches in the Royal Gallery leading from the Victoria Tower to the House of Lords; viz.:—Statues of Queen Elizabeth, James the First, Edward the First, and Queen Anne. These statues are of Caen stone. The sculptor is Mr. J. B. Philip. The statues which had previously been placed were those of Richard the First, Edward the Third, Alfred the Great, and William the First. Only four niches now remain to be occupied.

IT was officially reported on July 1 that a very rich gold field had been discovered at Trunkey Creek, which lies in the west, about thirty-eight miles from Bathurst and sixteen from Careoar. The field is described as consisting of auriferous quartz reefs, in which the precious metal is very abundant. These reefs have been marked off for six miles, and fresh discoveries in the vicinity are reported daily. The district is mountainous for many miles around, and, besides bearing gold, has silver, copper, iron, marble, and limestone. It is also a purely agricultural country. All the gold-bearing reefs run north and south, and dip slightly to the west. A report is current to the effect that there are already 800 people on the ground, and the whole neighbourhood is in a ferment.

THE "Ironmonger" suggests the desirability of constructing trains wholly of iron. They might be so constructed of this material as certainly to offer greater power of resistance in case of collision, and this without materially augmenting their weight, whilst the danger from fire would be almost nil. With strong frames, properly braced, the sides might be covered with comparatively thin sheets of iron. Railway companies cannot certainly be expected, in view of the large intermediate outlay that would be involved in an entire change of rolling stock, to carry out at once the suggestion, but the transformation might be effected gradually, and all carriages hereafter constructed might be of iron. These iron cars would doubtless be more lasting, and, in the end, more economical. Our large iron manufacturers would do well to give this subject their attention.

PROFESSOR G. CAMPANI, of Siena, has been investigating the action of permanganate of potash on asparagine, the vegetable base of asparagus, but which may also be extracted from the roots of marshmallows and various other plants. The results he has arrived at are as follows:—1. That asparagine exercises a slow reaction on permanganate of potash at the common temperature, when both these substances are dissolved in water. 2. That the former acts quickly and powerfully on the other when both substances are reduced to powder, then mixed together, and afterwards moistened with a little water. 3. That their reaction is equally prompt and strong when, being dissolved in water, their mixture is heated to ebullition, and much more so if sulphuric acid or caustic potash be added. 4. That under such circumstances asparagine yields nearly the whole of its nitrogen in the shape of ammonia, and a little of it in that of prussic acid, but never in a free state. 5. And that carbon is chiefly disengaged under the form of a carbonic anhydride or oxalic acid; and very little of it under that of hydrocyanic and formic acid.

Patents for Inventions.

ABRIDGED SPECIFICATIONS OF PATENTS.

THE Abridged Specifications of Patents given below are classified, according to the subject to which the respective inventions refer, in the following table. By the system of classification adopted, the numerical and chronological order of the specifications is preserved and combined with all the advantages of a division into classes. It should be understood that these abridgments are prepared exclusively for this Magazine from official copies supplied by the Government, and are, therefore, the property of the Proprietors of this Magazine. Other papers are hereby warned not to produce them without an acknowledgment:—

BOILERS AND FURNACES—754, 784, 786
BUILDINGS AND BUILDING MATERIALS—742, 764, 777
CHEMISTRY AND PHOTOGRAPHY—744, 761
CULTIVATION OF THE SOIL, including agricultural implements and machines—761, 767, 795
ELECTRICAL APPARATUS—770, 797
FIBROUS FABRICS, including machinery for treating fibre pulp, paper, &c.—752, 756, 759, 772, 773, 776, 789, 796, 799 802, 811

FOOD AND BEVERAGES, including the apparatus for preparing food for men and animals—738, 740, 767, 769, 778, 790, 798
FURNITURE AND APPAREL, including household utensils, time-keepers, jewellery, musical instruments, &c.—748, 750, 751, 760, 765, 780, 801, 803, 804, 813, 814
GENERAL MACHINERY—758, 768, 785, 787
LIGHTING, HEATING, AND VENTILATING—749, 753, 782, 784
METALS, including apparatus for their manufacture—755
MISCELLANEOUS—741, 743, 763, 766, 775, 781, 788, 791, 806, 807, 809, 815
ROADS AND VEHICLES, including railway plant and carriages, saddlery, and harness, &c.—737, 748, 775, 800, 805, 808, 810, 816
SHIPS AND BOATS, including their fittings—744, 762, 770, 774, 792, 794, 812
STEAM ENGINES—746
WARFARE—729, 757, 779, 783, 793

737 F. O. PALMER, Hurstpierpoint. *Conveyances.* Dated March 10, 1869.
The inventor uses a car hung to the axis of a pulley or pulleys running on a line or lines, which may be of wire, chain, rope, or other material, and the car is caused to travel to and fro from end to end of such line by bringing the line into an inclined position so that the car may descend along it by gravitation. For the purpose of raising and lowering the ends of the line each end of the line may be attached to a pillar which can be raised or lowered at pleasure, either by a rack and pinion or by hydraulic pressure or by other suitable means, or the end of the line might be attached to a slide capable of being raised or lowered by any suitable means upon a pillar, or the end of the line might be unhooked from the point of the post and hooked on to another point on such post so as to alter the angle of the line, or the end of the line might be attached to the end of a lever and be raised or lowered by running such lever on its axis.—Patent completed.

738 G. SPENCER, Cannon-street, E.C. *Preserving grain, &c.* Dated March 10, 1869.
The inventor places the substance to be preserved in a suitable air-tight vessel from which atmospheric air is partially or wholly withdrawn by any convenient means, and replaces it by filling the containing vessel with either carbonic acid gas or carbonic oxide gas, by which means the substances are preserved from change.—Patent abandoned.

739 A. MONCRIEFF, Culfargie, Perth. *Ordnance.* Dated March 10, 1869.
This relates to a patent dated 4th June, 1866 (No. 1548), and consists in so arranging the counterweight connected to the elevators that the gun, on sinking down after firing, can pass below the counterweight so as to be more accessible for loading and more under cover. For this purpose the inventor constructs the counterweight with an opening through which the muzzle of the gun or the counterweight may be constructed of separate parts between which the gun passes.—Patent completed.

740 D. JOHNSON, Wrexham. *Decorticating grain.* Dated March 10, 1869.
This consists chiefly in the arrangement together of two filing or rasping surfaces by which the grain is acted upon as it passes between them, and in certain details of construction hereinafter described. The files or rasps are fixed on a drum and case. The drum is made to revolve within the case. The wheat, rice, or other grain is admitted into the space between the drum and case and is therein subjected to the action of the files or rasps, which rapidly and effectually clean and remove the husks therefrom.—Patent completed.

741 J. B. BERNIER, Wilmington-square, E.C. *Preserving yeast for manure.* Dated March 11, 1869.
The process consists in mixing yeast with a suitable proportion of quicklime, to which some plaster may be added; this mixture produces a good manure. The proportion varies according to the condition of the yeast, but generally 30lb. of quicklime and 10lb. of plaster is used to every hundredweight of yeast is best.—Patent completed.

742 T. H. HARRISSON, Liverpool. *Waterclosets.* Dated March 11, 1869.
This consists of an enlargement of the main pipe, or a chamber situated between the ordinary valve cock and the watercloset basin, from the top of which vessel or chamber an air pipe is taken into the basin by the side of the supply (or air is otherwise admitted), so that when the valve cock is lifted and the water turned on, the vessel is instantaneously filled and the supply rushes forward into the basin unchecked in force. When the valve is reclosed the air releases the store of water or back-wash, which then flows into the basin and securely traps the closet.—Patent abandoned.

743 W. WELLS, Ardwick. *Sanitary apparatus.* Dated March 11, 1869.
This consists in an improved privy, which is so constructed that the solid portion of the excreta is kept separate from the urine, thereby keeping the solid portion dry and facilitating its removal. In carrying out the invention the inventor places a drum rotating on a horizontal axle or slightly conical disc mounted on a vertical or nearly vertical axle under the pan or seat of the privy, and this drum or disc is made to revolve partly round every time the privy has been used by a footboard which is hinged to the floor or by the seat itself, the footboard or seat being connected to the drum or disc by a lever catch and ratchet wheel or other equivalents, and when pressure is removed from the footboard or seat it is brought back to its original position by a counterweight. When the privy has been used the urine runs off the drum or disc, while the solid matter adheres to it, and when the drum or disc is turned partly round by the moving of the footboard or seat the solid matter is scraped off by a thin blade of metal or other suitable agent, and is collected in a separate vessel, from which it can be removed at any time.—Patent completed.

744 G. GLOVER, Pimlico. *Colouring hydrocarbons.* (A communication.) Dated March 11, 1869.
The colour best suited for the purpose is derived from the root of the "anchusa avensis," known in commerce by the name of alconet root, which imparts to the fluid a rose tint. Or the inventor takes the common turmeric of commerce (curaima longa), which would impart a yellow tint. Or he uses indigo (fera tinctoria) or prussate of iron, or any of the blue anilines, by first dissolving them and then mixing them within the hydrocarbon, which imparts a blue tint. Or the tint may be changed by any vegetable, animal, or mineral colour, so as to impart the special tint intended.—Patent completed.

745 W. H. CLAPP, Ball's Pond. *Signal lanterns.* Dated March 11, 1869.
The lamp of the lantern is surrounded with a revolving cylindrical slide, such as is used in an ordinary dark lantern, there being an opening made through the cylinder, which, when brought between the lamp and the lens or glass of the lantern, allows a stream of light to pass from the lantern. In some cases the lantern may be made with more than the lens or glass.—Patent completed.

746 J. and A. WADDINGTON and F. BELL, Barrow-in-Furness. *Condensing steam in breweries.* Dated March 11, 1869.
This consists in causing the steam, and the smell arising therefrom, to be condensed by coming into contact with a lid or cover, over or through which a current of cold air or cold water, or other liquid or fluid is caused to pass.—Patent completed.

747 W. BETTS, Wharf-road, City-road. *Capsules.* Dated March 11, 1869.
Capsules made according to this invention are perforated in any ornamental or other pattern or device, so that the contents are not hermetically sealed, whilst they are nevertheless at the same time protected from being tampered with. This perforation of the capsule can be effected in any convenient manner, but it is found that stamping is the most ready mode of accomplishing it.—Patent completed.

748 C. H. COOPER, Birmingham. *Whip sockets.* Dated March 11, 1869.
This consists in fixing, by stitching or otherwise, an internal lining from the mouth of the socket downwards. The lining is of any suitable material, such as leather, sheet gutta-percha, or suitable prepared waterproof cloth, and formed from the plain without moulding of one or more pieces or thicknesses partially divided vertically by the removal of parallel arranged gores, that is to say, pieces removed broader in the middle, and curving off towards the end.—Patent completed.

749 J. BATHGATE, Edinburgh. *Gas meters.* Dated March 11, 1869.
The case of the meter is constructed in two distinct parts, an under part and an upper part, the under part containing the movable diaphragms and passages thereto, whilst the upper part encloses the valve box and valves with the regulating and indicating mechanism, none of which, however, are attached to it, but are placed on the top of the under part, the upper part merely serving as a protective covering for them, and these two parts, namely, the upper and lower parts of the case, are put together by means of screws or other similar fastenings. The valve box is made separately, by preference, of cast metal, and is also retained in place by means of screws.—Patent completed.

750 W. E. NEWTON, Chancery-lane. *Cigar cases.* (A communication.) Dated March 11, 1869.
This consists in a case, of double hollow leaf form, struck or cut, and stamped (with corrugated formations to form pockets for the article or articles it is designed to carry) out of a single piece of sheet metal or other suitable material. The corrugated sheet is then folded intermediately of its length to constitute a spring hinge or connection and gives to the case its necessary hollow double leaf or book form. This completes the case, which may, however, afterwards be lined with paper or other thin material, and, if desired, any suitable fastening may be applied thereto.—Patent completed.

751 W. E. NEWTON, Chancery-lane. *Attachment for picture cords.* (A communication.) Dated March 11, 1869.
This consists in the use of tubes formed with longitudinal or transverse notches or slots provided or not with pins, hooks, or teeth. The improved attachment is cut out of sheet metal, and is made with wing pieces, which are bent up to form tubes to receive the cord, the notches in the sides of the upper part forming transverse notches at the ends of the tubes, and the notches in the lower part forming longitudinal notches in the sides of the tube, so that the cord may be secured in place when adjusted by drawing it into one or the other of these notches.—Patent abandoned.

752 T. GREENWOOD, Leeds. *Preparing fibres.* Dated March 11, 1869.
The inventor provides a novel arrangement of mechanism, which will enable him to accumulate the fibrous material fed thereto, and to form it into a lap or sliver, and then strip it off the retaining surface and deliver it out of the machine ready for undergoing the operations of the drawing frame.—Patent completed.

753 J. H. JOHNSON, Lincoln's Inn-fields. *Artificial fuel.* (A communication.) Dated March 11, 1869.
This consists in the manufacture by means of vegetable resin, used in proportions determined according to the product to be obtained, of:—First, agglomerated fuel, produced from small vegetable and mineral fuel or the dust thereof, and intended to be consumed in furnaces and ordinary domestic firegrates. Second, dense coke capable of being employed for the same purpose. Third, lighting gas and dense coke produced simultaneously, vegetable resin thoroughly mixed with fuel dust and properly burned, produces a coke of good quality, whilst the dust employed alone either yields an inferior coke or is not capable of producing coke at all.—Patent completed.

754 H. ORMSON, Chelsea. *Boilers.* Dated March 11, 1869.
The internal boiler may be of a concentric, convolutic, or multitubular shape, and the boiler is made with more or less number of tubes or convolutions according to use.—Patent completed.

755 J. M. NAPIER, York-road, Lambeth. *Striking coins.* Dated March 11, 1869.
This consists in machinery or apparatus for cutting into pieces the ingots of metal to be manufactured into coins, so as to facilitate the charging of the crucibles, and afford a means of detecting the presence of foreign substances in the ingots. For this purpose, the inventor employs a suitably formed knife actuated by hydraulic pressure (lever pressure may be used if preferred). This knife operates towards an anvil, against which the ingot is supported. He employs means for regulating the edge of the anvil in its position with respect to the edge of the cutting knife, so that the piece to be cut off the ingot is supported by the anvil or block partially only and in such manner that, as the knife is forced into the metal, the front part of the ingot which overhangs the front edge of the anvil.—Patent completed.

756 G. SMITH, Headingley. *Finishing woollen cloths.* Dated March 11, 1869.
The materials employed are British and foreign gums; dextrine and gum senegal or gum tragacanth, with refined sulphate of indigo, which are ground and sifted into a very fine powder, in which state they may be sold for use.—Patent abandoned.

757 F. R. AIKMAN, Brompton-crescent. *Firearms.* Dated March 11, 1869.
This relates to a patent dated July 8, 1867 (No. 1934). The inventor attaches to the gun in any convenient position a small barrel, such as that of a rifle or pistol. He mounts this barrel on a horizontal pivot or axis, and applies to it a scale for vertical adjustment with a screw or other convenient apparatus for setting it so that its line of fire can be made parallel to the line of sight of the gun to which it is attached, or can be elevated or depressed as desired.—Patent abandoned.

758 T. BEELEY, Chester, and D. HANSON, Dukinfield. *Welding and flanging tubes.* Dated March 11, 1869.
This consists in a machine by means of which the blows necessary for welding the seams of boilers and other constructions are struck, instead of employing a number of labourers for this purpose as at present. This is accomplished as follows:—The machine consists of a number of stampers or strikers which are arranged side by side in a row. The stampers or strikers, are so arranged that they may be raised to a certain definite height, and then be allowed to fall by their own weight, or the force of the blow may be increased by means of a spring. Below this row of strikers or stampers is placed the anvil, which may be similar in shape to that now in use for this purpose, or curved to the requisite form for welding or flanging.—Patent completed.

759 W. R. LAKE, Southampton-buildings. *Spinning fibr* (A communication.) Dated March 11, 1869.
The spindle is stepped in a foot rest which projects from the lifting rail, which is made to traverse by any suitable mechanism. The upper end of the spindle is furnished with a square and flange in order to provide a means for driving the bobbin by the application of the driving power to its upper instead of its lower end.—Patent completed.

760 W. COXHEAD, Gresham-street. *Goloshes.* Dated March 12, 1869.
This consists in modifying the shape or form of india-rubber goloshes or shoes so as to adapt them to the peculiar conformation of feet and shoes of the Chinese and other eastern nations.—Patent abandoned.

761 E. F. R. LUCAS, Middlesborough-on-Tees. *Manufacture of phosphate of lime.* Dated March 12, 1869.
The coprolites, cair ashes, phosphorites, or other phosphates are first dissolved in hydrochloric acid. The solution thus produced is evaporated by any of the well-known means to the crystallising point, and the liquor is then run off into cooling vessels of stone or wood. In cooling, the greatest part of the soluble phosphate of lime is crystallised, the mother liquor is drawn off from the crystals; evaporated again it gives a second quantity of crystals of soluble phosphate of lime. The crystals are then dried by means of air, centrifugal apparatus, or pressed in a filter press. The last mother liquor contains chloride of calcium, chloride of iron, and only a small quantity of phosphate of lime, which phosphate of lime is precipitated by means of caustic lime, and redissolved in hydrochloric acid, together with a fresh quantity of phosphate.—Patent abandoned.

762 H. J. B. KENDALL, Great Winchester-street. *Paint for ships' bottoms.* (A communication.) Dated March 12, 1869.
The composition consists of the following ingredients:—Arseniate of copper, oxide of iron, carbonate of lime, crystallised strychnine, concentrated anhydrous extract of tobacco, and crystallised borax. To these ingredients coal tar or other base or medium, or coal tar with other base or medium, is added, according to the colour required, and the whole is ground together.—Patent completed.

763 J. PORTEOUS, Edinburgh, and H. GIBSON, Musselburgh. *Tobacco.* Dated March 12, 1869.
This consists of a shaft or spindle on which circular flanges (by preference with openings formed in them) are placed, the distance between these flanges being equal to the length of the rolls which are to be coiled. On the end of the above-mentioned spindle a worm or screw is fitted, and this gears into a worm wheel carried on a stud or cross shaft. To the body of the worm wheel a heart or other shaped cam is fixed which acts against an anti-friction roller carried on a horizontal guide rod, this guide rod being jointed to a lever to which the vibrating action due to the cam is communicated. In lieu of the cam a double cut screw may be employed for giving the requisite movement to the lever and guide rod. Attached to the upper end of the vibrating lever is a horizontal sliding bar, to which the reciprocating movement of the lever is communicated; as the cam above mentioned revolves on that end of the sliding bar next to the flanges, between which the tobacco is coiled, a tube or eye piece is fitted, through which the twisted tobacco passes, so that it is unwound from the bobbin on which it was wound on the twisting machine, the reciprocating movement of the tube or eyepiece causes it to be coiled closely and regularly between the flanges on the main spindle.—Patent completed.

764 D. S. PRICE, Great George-street, S.W. *Paving.* Dated March 12, 1869.
This consists in the use of blocks of cast iron, the surface or surfaces of which are hardened by the process of "chilling," or which are made of the description of cast iron for which letters patent were granted to the same inventor, and E. C. Nicholson, dated November 20, 1865 (No. 2618).—Patent abandoned.

765 E. PRITCHARD, Fenchurch-street. *Button or stud.* Dated March 12, 1869.
The inventor forms the button or fastening in two parts, which, when connected together, present the appearance of a shirt stud. He forms the shank of the button in two parts, and of short tubes, one tube being fixed on one part of the button, and the other tube on the other part thereof, and in the centre of one of these tubes the inventor fixes a screwed pin, and in the hole of the other tube he forms

a female screw capable of fitting on to the screwed pin.—Patent abandoned.

766 G. Bray, Deptford. *Disengaging hook.* Dated March 12, 1869.

The inventor provides the pole head of the carriage with divided eyes or rings which do not require any shackle connection, as they can be made to form parts of the pole head itself. These eyes or hooks are so made that one part moves upon a pin or joint against one end of which a spring catch is fixed, by operating on which the ring or eye is opened so that a link of a chain or other connector can be passed on to the ring or eye, and by again pressing the spring catch it will be closed, and the connection rendered complete.—Patent completed.

767 J. Cooke, Lincoln. *Ploughs.* Dated March 12, 1869.

This consists in manufacturing an improved beam for ploughs of a combination of wood and iron or of wood and steel.—Patent completed.

768 H. J. Cenant, Tubize, Belgium. *Steam cocks.* Dated March 12, 1869.

Instead of using a conical plug fitted to a corresponding seat, the inventor provides the cock with a flat-faced valve seat which is pierced with holes for connecting the supply with the exit passage of the cock. To this flat-faced valve seat he applies a disc valve pierced with corresponding holes, which, when brought into coincidence with those of the seat, will open the exit passage for the discharge of steam or water through the cock. This disc is secured to the end of a stem which carries a handle for operating the cock.—Patent abandoned.

769 C. E. Brooman, Fleet-street. *Manufacture of salt.* (A communication.) Dated March 12, 1869.

This relates to the manufacture of salt, and has for its object a process for the manufacture of a crystallizable salt in special vessels, which process is founded partly on the employment of mechanical means and partly upon the theory of the tension of saturated vapours, in order to constitute an evaporising apparatus utilising one, two, or more consecutive times the latent heat of the vapours condensed away from the air, and in consequence economizing the combustibles used in the manufacture.—Patent completed.

770 L. Labadie, Bordeaux. *Magnetic regulator.* Dated March 12, 1869.

This consists in the employment of substances very sensible to magnetism, such as iron, cast iron, steel, or nickel, in order to compensate for the disturbing effects of the iron of the ship upon the compass needle. The inventor has found that a cylinder composed of the metals above named is a good conductor of magnetism, and has the property of preserving the magnetized needle from the influence of the currents proceeding from the iron composing the ship, and at the same time of preserving its freedom of action.—Patent completed.

771 J. Duffey, Chelsea. *Railway brake and coupling.* Dated March 12, 1869.

This consists in arranging curved brake surfaces connected together and pendant in front of each pair of wheels from a point of the framing above the latter. The brakes are connected together by suitable rods, so that they may be applied to all the wheels of the engine or carriage at once upon releasing a hand lever, which holds them back from the wheels.—Patent abandoned.

772 A. M. Clark, Chancery-lane. *Pulp for paper.* (A communication). Dated March 12, 1869.

This relates to the production of pulp from the hop bine suitable for the manufacture of paper. For this purpose the inventor first cuts up the bine into suitable lengths by mechanical means, whether in a green or dry condition, and then subjects it to a series of washings in water until the ligneous fibres are perfectly purified.—Patent abandoned.

773 H. C. Bartlett, Garlick-hill, and A. G. Southby, Bulford. *Paper making.* Dated March 13, 1869.

The inventors use for the purpose of separating, beating, washing, or mixing fibrous substances mixed with more or less water, a cylinder box, containing either plates or bars or projections fixed to the side or sides, so that the plane of the plates or bars or projections shall be at a right or other angle to the axis of one or more shafts running through from end to end of the cylinder or box having on the shaft or shafts radiating or spirally disposed bars or plates or projections the converse of those on the inner part of the cylinder or box and working between them.—Patent completed.

774 W. H. Harfield, Royal Exchange-buildings. *Capstans.* Dated March 13, 1869.

In order to work a windlass by means of a capstan through toothed gearing, where the cable is taken to the under side of the windlass, the inventor proposes to employ skew bevel gearing (in place of the ordinary bevel gearing heretofore used) so as to enable the vertical shaft to pass the horizontal shaft.—Patent completed.

775 J. B. Palmer, Bow. *Matches.* Dated March 10, 1869.

This consists in using, as the igniting composition in ordinary friction matches and fusees, chloride of potash, and amorphous phosphorus in the proportion of sixteen parts of chlorate of potash to one part of amorphous phosphorus. These substances are combined with about twenty parts of the nitrate sulphite, sulphate, or the oxides of lead or the hyposulphite or sulphite of iron or zinc, or the sulphate of zinc or other sulphite or sulphate, or the twenty parts may be made up of two or more of the above substances in optional proportions. The above composition is mixed with about two parts of gelatine, glue, or gum, or any other suitable adhesive matter dissolved in water.—Patent abandoned.

776 H. Delattre, Roubaix. *New tissue.* Dated March 13, 1869.

The invention consists in making use of a web or warp of suitably twisted or twined worsted or woollen yarn, some of which warped yarns are twisted in one and the others in the opposite direction so as to alternate in a symmetrically regular manner over the entire breadth of the web. By this means a peculiar sort of shrivelling or shrinking will take place in the fabric, which will present a form hitherto unattained.—Patent abandoned.

777 P. B. O'Neill, Paris, and W. H. H. McNeight, Dublin. *Raising and lowering blinds.* Dated March 13, 1869.

A roller supported at each end in bearings is placed above the blind, one end of which is provided with a ratchet wheel. Into the teeth of this ratchet a spring pawl takes, and it always has a tendency to do so, but sometimes the ratchet and pawl is dispensed with. Outside the ratchet a groove is formed on the roller round which a cord is wound so that by pulling the cord a rotary motion is communicated to the roller. The laths composing the blind are united by tapes secured to the laths in the ordinary way, but at top they pass over the roller and are there supported on rollers or guides.—Patent abandoned.

778 E. W. and M. Slade, Wilton. *Portable oven.* Dated March 13, 1869.

This consists of an oven made preferably of a semicircular form, and of metal. When made of a non-metallic material it is lined inside with metal, as usual, for the purpose of reflecting and concentrating the heat from the fire before which it is placed. This improved oven is open at the side next the fire, and may be built up in sections one on the other in grooves formed around the upper edges of each section, so as to accommodate a number of joints at a time, according to the size of the fire. The oven may, however, be made in one piece, instead of removable sections. Each section is provided with one or more shelves or ledges for supporting a dish or pan or tray carrying a grating, on which is placed the joint to be cooked. The pan or tray also serves as a dripping-pan, and may be provided with a well in addition.—Patent completed.

779 J. Thomas, Birmingham. *Repeating firearms.* Dated March 13, 1869.

This consists in constructing and arranging the parts of repeating firearms so as to extract simultaneously the whole of the cases of the exploded cartridges from the chambers of the revolving barrels or cylinders of the arm, and also for effectually supporting the revolving barrels or cylinders during the discharge of the firearms.—Patent completed.

780 C. Vero, Atherstone. *Hardening hats.* Dated March 13, 1869.

The inventor covers the acting surfaces of the cones with fine wire gauze, to prevent the fibres spreading out. The cone of wire gauze for the inner cone upon which the hat body is placed, is woven by hand to the form desired, fresh wires being inserted into it at intervals, as the cone enlarges in diameter. This cone of wire gauze is placed upon the perforated metal cone, and is firmly bound to it at its base, or felt or cloth might be placed between the two. The conical lining of wire gauze for the upper cone is similarly woven to shape, and is placed within the metal cone and connected to it both at its base and apex, being at the base turned over and bound to its exterior, and at the apex attached by sewing to a small cup of perforated metal, similar to the cup to which the cloth lining heretofore employed was attached.—Patent completed.

781 J. Thomlinson, Carlisle, and W. Thomlinson, Loughborough. *Preparing gypsum.* Dated March 13, 1869.

In order to prepare gypsum for incorporating with paper pulp, previous to its being made into sheets, or for incorporating with textile fabrics, or for using, in other manufactures in the same manner as what is known as china clay is now used, the inventors calcine the gypsum in ovens or kilns or retorts, or in a cla mp or otherwise, with so high a degree of heat as to depri ve it of its cementing qualities. A full red or a white heat is required. The fuel for burning may in some cases be mixed with the gypsum, but when freedom from colour is desired it should be burnt in ovens or kilns fired externally.—Patent completed.

782 W. T. Carpenter, Westminster, Kent. *Manufacture of gas.* Dated March 13, 1869.

This consists in forming each of the retorts (which may be round, oval, or other convenient shape in transverse section) of an increasing diameter from the mouth to the back end, which is open and communicates with a chamber common to the whole setting.—Patent abandoned.

783 W. R. Lake, Southampton-buildings. *Breechloaders.* (A communication.) Dated March 13, 1869.

In using this arm there are only three movements to perform—first, the hammer is to be raised, and at the same time the trigger or sear is to be pushed forward; second, the charge is to be taken and introduced into the aperture in the barrel, which is uncovered by raising the hammer, the charge being pushed into the barrel with the thumb; and, third, the trigger is to be acted upon as in discharging any other firearm.—Patent abandoned.

784 J. Tenwick, Grantham. *Annealing ovens.* Dated March 13, 1869.

The inventor constructs the ovens and kilns of any required size, and of a circular form inside. The outside covering is made of iron or steel or any other metal suitable for the purpose, lined with firebricks, or other convenient material which can resist the fire; and firebars, ashpans, regulators, or dampers, and other accessories of the kind used in the construction of annealing ovens are provided.—Patent completed.

785 J. Henderson and T. Brown, Kirkcaldy. *Water cocks.* Dated March 15, 1869.

This consists in forming the body of the cock as a hollow cylinder, through which the spindle or stem of the valve passes. The inner part of the body of the cock consitutes the valve seat, and the stem or spindle passes out through the front end of the cylinder or body.—Patent abandoned.

786 W. A. Martin, Union-street, Borough. *Steam generators.* Dated March 15, 1869.

This consists in causing the highly heated steam from the upper part of the boiler to pass downwards nearly to the bottom of the boiler, where the water is comparatively cold and sluggish, for the purpose of assisting to heat and thereby to promote the circulation of the water. This is done by providing near to the boiler bottom a steam space, or steam or steam spaces, having a communication or communications extending upwards into the upper part of the steam space above the water level or nearly to the crown of the boiler.—Patent abandoned.

787 E. Sands, Manchester. *Rotary engine.* Dated March 15, 1869.

The inventor makes use of two or more fixed axles placed in the same vertical line and plane; on each of these axles is a pair of three-armed levers; connected with these levers and at any convenient distance from them are two or more pairs of toothed wheels, mounted on separate axles, whose lower periphery gear into stationary racks attached to the framework of the machine.—Patent abandoned.

788 J. C. Shaw, Patricroft, Lancaster. *Card grinder.* (A communication.) Dated March 15, 1869.

The inventor uses an ordinary hollow grinding cylinder, but the axle is composed of two distinct shafts. At each end of the cylinder is a long boss to which it is secured. The bosses are so connected to the shafts that they are capable of a rotary and lateral motion simultaneously. To the shaft at the driving end of the cylinder is fastened a pulley, and in the same shaft is cut a straight groove equal to the length of the traverse. A screw or other equivalent is fastened in the boss with its point projecting into the groove of the shaft, thereby transferring the rotary motion of the shaft to the boss, and, consequently, to the grinding cylinder.—Patent abandoned.

789 C. D. Abel, Southampton-buildings. *Weaving healds.* (A communication.) Dated March 15, 1869.

This consists in constructing healds of thin metal bands tapering in thickness from near the middle of their length towards each end. At the middle they are flattened in a direction at right angles to their width, and are there formed with an eye through which the warp thread is passed; they are formed with hooks at their ends, and are connected to the top and bottom staves of the frame by means of helical springs or coiled wires, into the loops of which they are hooked, and which are carried upon rods or bars passing through loops fixed to the staves.—Patent completed.

790 H. D. Rawlings, Nassau street, W. *Filling bottles.* Dated March 15, 1869.

The neck of the holder of the bottles or other receivers used during the filling and corking processes is capable of being open through a suitable tap or valve to the exhaust apparatus, as well as to the aerated liquid to be supplied to the bottle or other receiver. The atmospheric air contained in the receiver may, therefore, first be withdrawn and then, whilst the interior of the bottle or other receiver is in a state of exhaustion, the aerated liquid supplied thereto.—Patent abandoned.

791 J. G. Jennings, Palace-road, Lambeth. *Preparing sewage for irrigating land.* Dated March 15, 1869.

In order to separate from sewage, stones and other masses of solid matter which it brings down with it, the inventor conducts it through a pipe or channel on to a grating, which may be either horizontal or inclined upwards from the end on to which the sewage is delivered. The bars of the grating are arranged to run longitudinally from one end of the grating to the other, and in order to keep the spaces between the bars clear, and carry off from the upper surface of the grating the solid matters stopped by it, the inventors employ clearers, which are caused to rise up between the bars at the end at which the sewage comes on to them, and such clearers are then caused to travel up to the opposite end of the grating, carrying forward with them the solid matters resting upon the grating; the clearers then travel back and again rise up between the bars of the grating, at the end of which sewage comes on to it; the solid matters are thus caused to fall over the edge of the grating into a pit or receptacle.—Patent completed.

792 G. P. Evelyn, Pall Mall. *Sails, yards, and rigging.* Dated March 15, 1869.

The sail is laced to a boomyard, which is divided at about two-thirds of its length by double jaws or a strong metal ring which embraces the mast. The gaff yard embraces the mast in a similar manner, and the sail is divided at the mast and attached to it by rings or hoops which slide up and down it. The mast is supported by revolving stays or shrouds.—Patent abandoned.

793 J. R. Cooper, Birmingham. *Breech-loaders.* Dated March 14, 1869.

The inventor effects the opening and closing of the breech by means of a block raising and falling vertically. The block when raised closes the breech, and when dressed leaves it open. Through the block and in a line parallel with or inclined to the axis of the barrel is a hole in which a striker works for igniting the cartridge. The raising and lowering of the block is effected by a lever which may constitute the trigger guard of the gun. By the motion of this lever, the cocking of the hammer of the gun and the extraction and ejection of the empty cartridge case are effected.—Patent abandoned.

794 W. R. Lake, Southampton-buildings. *Steam vessels.* (A communication.) Dated March 15, 1869.

This consists in fitting a longitudinal truss or deep keelson rising vertically within the vessel to a height sufficient to stiffen her and prevent injury by the weight, whether riding upon or between waves. By this construction, the vessel presents less hydrostatic resistance and draws less water for the same capacity of burden, and is very strong to resist the effects of strain or torsion.—Patent completed.

795 W. R. Lake, Southampton-buildings. *Multiple drilling machine.* (A communication.) Dated March 15, 1869.

This consists chiefly in constructing and arranging the drilling mechanism in such a manner that the required number of holes may be drilled at the same time, at any desired distance apart, in a rail bar or other article, and so that in drilling these holes the drills will adapt themselves to such variations or deviations from a straight line or plane as are produced by the twisting or warping of the rail or other article, and will form the holes at right angles to the immediately surrounding portion of the rail or other article.—Patent completed.

796 J. Taylor, R. and J. Ingham, and J. Sharplis, all of Crawshaw Booth, Lancashire. *Carding engines.* Dated March 16, 1869.

The inventors divide the doffing cylinder so as to meet a double exigency, viz., first to obtain a continuous fleece, so as to dispense with piercing machinery, and second, to obtain a sliver neither twisted, half twisted, or rubbed.—Patent abandoned.

797 W. A. Lyttle, Hammersmith. *Insulating telegraph wire.* Dated March 16, 1869.

The inventor uses enamelled iron, either wrought or cast, in forming the stems which support the "inverts" or other insulating caps such as are now employed.—Patent completed.

798 W. M'Adam and S. Surman, Glasgow. *Packing bottles.* Dated March 16, 1869.

The cases made of pulped material are formed with grooves, flutes, or indentations of various shapes, either on their inner or outer surfaces, which are intended to reduce the surfaces of contact of a series of points or lines, thus imparting a certain amount of elasticity to the cases.—Patent completed.

799 O. Whittaker and H. and I. Wallwork, Hurst, near Ashton-on-Lyne. *Saddles and hangers for spinning machinery.* Dated March 16, 1869.

This consists principally in dispensing with the use of

brass gun metal or other metallic alloy for the bearing surfaces of these parts of preparing and spinning machinery, and substituting therefor hard wood, such as lance or box wood, with the end of the grain towards the bearing surface.—Patent completed.

800 F. Render, Manchester. *Carrying minerals.* Dated March 16, 1869.

The inventor erects the line of rail elevated above the ground by placing it upon the swerved trunks of trees when they exist, or by driving piles. Upon this single rail he places a frame provided with two or a greater number of wheels situate in a line before each other, and from this frame he extends downward arms which carry on each side of the rail an engine and boiler of equal weights.—Patent abandoned.

801 W. Campion, Nottingham. *Sewing machines.* Dated March 16, 1869.

Motion is imparted to the needle slide by one end of a lever the other end of which is actuated by a cam mounted on a vertical axis, to which motion is given by means of a toothed ring formed on or fixed to a fly wheel mounted on an axis at right angles to such vertical axis. At the lower end of this vertical axis is carried a crank pin for working the shuttle slide to and fro in a line with the length of the machine, such crank pin being connected to the shuttle slide by a link or connecting rod as usual. The vertical axis also carries a double cam to act on one end of the feed lever, which is mounted upon a compound axis so as to permit of the movements of the feed lever to feed the fabric as required.—Patent abandoned.

802 W. Robertson, Queen's-chambers, Manchester. *Mules and turners.* Dated March 16, 1869.

The chief improvement refers to the backing off. In place of the wheels and friction cones, which are usually placed on the headstock and operate through the twist band, the inventor places a pulley on the second, third, or other similar motion from the loose pulley communicating motion in a backward direction to a pulley placed loose on the tin roller shaft, and having a friction cone on one side thereof, which is brought into contact with another cone on the tin roller pulley and moves it in a backward direction.—Patent completed.

803 L. Engel, Mumford-court, E.C. *Umbrellas.* Dated March 16, 1869.

In order to avoid the covering of silk or other material being worn by the end of the stretcher where it is jointed to the rib and by the pin or rivet of the joint, the inventor attaches to the rib at this point a guard of metal which is formed with two side plates to overlap the joint which connects the stretcher with the rib, and by so doing keeps this joint from rubbing against the covering. —Patent completed.

804 J. L. Norton, Belle Sauvage-yard, E.C. *Weaving looms.* Dated March 16, 1869.

In constructing the shedding motion of looms the inventor arranges the mechanism for working the heddles so that the frame work and slides for the knives, as usually constructed, are rendered unnecessary. In place of the framework a simple upright bracket is used, which can be easily attached to any ordinary loom frame. To this upright bracket is fixed the mechanism for working the heddles, and the knives and levelling levers are arranged for producing a proper ◁ shed. The lever for actuating the knives and levelling levers works on a stud fixed to the loom frame, so that vibration in the upright bracket is as nearly as possible avoided and stays or supports are not required.—Patent completed.

805 W. and C. S. Catt, Ipswich. *Joints of carriage shafts.* Dated March 17, 1869.

In making a combined joint and stop according to this invention the inventors construct and arrange the parts as follows:—That part to which the shaft is to be jointed consists of two plates of steel or iron fixed to the carriage, between which plates a filling up piece of wood is secured by bolts. The outer ends of these plates are of a nearly circular figure, and holes are made in their middle. The curved and perforated ends project beyond the filling-up piece of wood and constitute the outer eyes or knuckles of the shaft joint. At the junction of the outer knuckles, with the steel or iron plates from which they are made, are shoulders which form stops against which the other part of the joint abuts when the shaft is raised. To the end of the carriage shaft a forked plate is riveted, the solid end of which carries a knuckle or eye of a size proper to fit between the outer eyes or knuckles.—Patent completed.

806 E. Roper, Garrick-street, and G. Shaw, Stoke-on-Trent. *Printing blocks.* Dated March 17, 1869.

The inventors transfer on to the plates of compressed chalk, in the ways hereinafter described, prints or mouldings from casts or reliefs, or intaglios produced by photography or otherwise, or they copy these reliefs or intaglios on to the plates by means of any suitable pentagraph or other suitable copying apparatus, and thus adapt the graphotype process to the reproduction and multiplication of drawings, woodcuts, engravings, photographs, lithographs, or other printed matter.—Patent completed.

807 J. James, Princes-street, Lambeth. *Compressing powder in pellets.* Dated March 17, 1869.

The inventor mounts on a framing a punching slide, which is worked up and down by an eccentric, cam, crank, or other convenient mechanism. Under this slide he mounts a disc, which can turn on a vertical axis. In this disc he perforates numerous holes, each of the shape desired for the transverse section of the pellet, and makes the thickness of the disc to suit the length desired for the pellet. All these holes are equally distant from the centre of the disc, and are spaced at equal intervals around it. On the axis of the disc a ratchet wheel is fixed with teeth suited to the holes in the disc, and to this ratchet wheel the inventor applies a pawl, which is worked with reciprocating movement by a cam or eccentric on the driving shaft of the apparatus, so that the movement of the disc one division at a time is suitable to the movement of the slide.—Patent abandoned.

808 E. W. P. Gibbs, Westbourne Park-crescent. *Velocipede propulsion.* Dated March 17, 1869.

This consists in the use of two levers with unequal arms, which levers are attached on opposite sides of the rear wheel by nuts or pivots to cranks, which pass through and are firmly fixed to the axle of the rear or hind wheel The crank on one side of the wheel is to be at opposite angles to the crank on the other side of the wheel, or, in other words, the two cranks are fixed in opposite directions in parallel planes.—Patent abandoned.

809 B. Latham, Westminster-chambers. *Filtering and straining sewage.* Dated March 17, 1869.

This consists in causing the sewage or other fluid to be filtered to pass, on its way along or as it issues from a conduit, against and through a travelling screen or sieve, or combination of screening surfaces arranged at right angles, or at any other convenient angle to the flow of the fluid, whereby the sewage or other fluid, as it passes through the screening surfaces, deposits its solid matter upon the latter. In travelling along the screening surfaces carry such matter away to a point where it is removed from them, and they then again pass into the stream of sewage to intercept fresh matter.—Patent completed.

810 T. Rickett, Birmingham. *Velocipedes.* Dated March 17, 1869.

This consists in constructing velocipedes with two large very light wheels which run loose on one plain axle, and from the axle between the wheels the inventor suspends a seat, and attaches a cushion on or immediately above, the axle; the height of the seat is adjustable, and is made so that when the operator sits upon it he may lean upon the axle cushion with his arms. The seat slings are attached to the axle by a hook or button, so that the operator, having detached one side of the seat, places himself, when erect, between the axle and the seat. He then reattaches the sling to the axle and sits upon the seat. The carriage, therefore, in its simplest form, consists of a pair of wheels and axle, with a seat slung from it proportional, so that the entire weight of the body may be balanced on the seat, or the feet may be used for propelling, and the weight of the body be carried partly by the seat and partly by the arms resting on the axle, or under certain circumstances wholly by the axle. But it is preferred to construct these carriages also with a brake, a rest for the feet, and a provision for carrying small articles. For this purpose the inventor constructs a pair of light, triangular, but carved frames, the apex or top of each frame being connected to the axle, and the under side or base forming in the front a foot rest by a stay connecting the two frames together within the radius of the wheels, and at the back of each frame terminating in a brake block which projects beyond the radius of the wheels and bears upon the ground when desired. These frames, being free to swing, may in some cases carry the seat. A pair of rails or handles are detached to the hinder parts of the frames convenient for the hands, so that in descending an incline, or whenever it is desired to retard or arrest the motion of the carriage, the upper part of the body is thrown back, and the hands are placed upon the framing rails behind.—Patent abandoned.

811 J. J. G. Damitte, H. D. Dubois, and J. M. Agnellet, Paris. *Pulp.* Dated March 17, 1869.

This consists in the employment of the plant known in botany as the "Gallega Officinialiis" and "Galega Orientalis" plant, and in France as the Galega Rue de Chevre, Lavaneze or faux indigo plant for the manufacture of pulp suitable for paper. The plant is prepared and treated in a green state or in a dry state, in a similar manner to other fibrous materials for the same purpose.—Patent abandoned.

812 H. Claughton, Dumbarton. *Screw propellers.* Dated March 17, 1869.

This consists in constructing screw propellers with folding blades, that is to say, the blades are jointed or hinged to the boss or its equivalent in such a manner that they can be folded into a fore and aft position, and, without impairing the steering qualities of the ship, offer little or no resistance to her progress through the water when under canvas, or they can be folded more or less and thereby adjusted to suit the power applied and speed desired.—Patent completed.

813 J. Heywood and J. Wild, Tonge, and F. Murphy, Middleton. *Tapes for blinds.* Dated March 17, 1869.

The inventors form the tapes with tags or holders woven in the body of the tape for holding the laths, and thus prevent the liability of breakage. The tags are formed either of cords or small tapes, and are woven either in a line or at each side of the tape in a zigzag direction, and the cords can be woven either in an ordinary swivel loom or more efficiently in an improved loom. —Patent abandoned.

814 M. Rourke, Manchester. *Combining fabrics with pulp.* Dated March 17, 1869.

This consists in combining textile fabrics with paper in the paper making machine. The textile fabrics consist of calico, linen, cloth, Hessians, or any suitable material, and when the combined material is covered with oil, tar, or other liquids, it can be used as oil or tar cloths, floor cloths, table covers, packing, and for a great variety of purposes. The mode of operating is to supply the fabric to the pulp on the machine wire of the paper making machine, either under the dandy roller or a little in advance of it, and the pulp and fabric pass between the couch rollers, which press them together, and then they follow the course of the paper in ordinary paper making machines, and come out combined together.—Patent completed.

815 J. Carter, Nottingham. *Deodorising.* Dated March 17, 1869.

This consists in the employment of a dry chemical powder, composed of ground or crushed sulphate of lime or gypsum, used alone or in combination with certain proportions of dried clay or sand for water closets, privies, night chairs, or other commodes, instead of using water, ashes, or dry earth. This powder when brought into contact or combination with any kind of excrement or night soil, has the effect of completely and effectually deodorising such excrement or night soil, and rendering it entirely free from any offensive smell or effluvia, and at the same time it forms or produces a chemical manufacture of great fertilising properties, especially when applied to grass land or other green crops.—Patent abandoned.

816 H. Starr, Moorgate-street. *Harness hook.* (A communication.) Dated March 17, 1869.

The guard or tongue is pivoted between jaws in such a manner that when closed its free end covers the point of the hook. Between the jaws is a cavity or chamber wherein is enclosed a short spiral spring so arranged that its pressure tends always to close the guard, the spring being always completely covered and protected, whether the guard is opened or closed. At the back of the joint or pivot of the guard the hook is formed with a link or loop, whereby it is secured to a strap, cord, or rope.—Patent abandoned.

APPLICATIONS FOR LETTERS PATENT.

Dated September 28, 1869.

2814 W. Chambers, United University Club, Suffolk-street, Middlesex. An improved method of, and means for, ventilating.

2815 J. Taylor, Sheffield. Improvements in the manufacture of bradawls.

2816 W. Whiteley, Lockwood, near Huddersfield. Improvements in machinery or apparatus for roving and spinning wool, cotton, and other fibrous substances.

2817 R. and H. Harrild, Farringdon-street, City. An improved composition for the manufacture of printing rollers.

2818 C. D. Abel, Southampton-buildings, Chancery-lane. The production of a new or improved green colouring matter for dyeing and printing.

2819 J. Buchanan, Hebburn, Durham. Improvements in obtaining and applying a substitute for soda crystals, soda ash, or refined ash.

2820 J. Bullough, Accrington, Lancashire. Improvements in looms for weaving.

2821 H. Swan, Hammersmith, Middlesex. Improvements in the construction of millstones.

2822 J. W. Billiatt, Grantham, Lincolnshire. Improvements in elevators.

2823 H. J. D. Scott, Ealing, Middlesex. Improvements in pottery, lime, and other kilns.

2824 A. V. Newton, Chancery-lane. Improvements in the manufacture of horseshoe nails, and in the apparatus to be employed therein.

2825 W. R. Lake, Southampton-buildings, Chancery-lane. An improved method of, and apparatus for, preventing alteration of values in monetary instruments.

2826 W. R. Lake, Southampton-buildings, Chancery-lane. Improvements in harvesting machines.

Dated September 29, 1869.

2827 W. H. Noble, Holly House, Plumstead, Kent. An improved aerial carriage.

2828 A. J. Dulake, Redhill, Surrey. An improved pot or vessel for containing and conveying butter, lard, jellies, or other similar substances, and for an improvement in the form of lid or covering for such pots or vessels.

2829 J. Williams, Birmingham. Improvements in lifting jacks.

2830 W. Walker and D. Davies, Manchester. Certain improvements in furnaces for steam boilers and other purposes.

2831 W. Blunn and J. Wild, Kilnhurst, near Rotherham, Yorkshire. An improved furnace cistern for melting material from which glass is made, and for keeping the same in working condition during the process of blowing.

2832 D. Duthie, Edinburgh. An improved machine for tenoning timber.

2833 L. Wray, Ramsgate, Kent. Improvements in machinery or apparatus for crushing stone and other hard substances.

2834 W. and A. Kempe, Holbeck Mills, Leeds. Improvements in scrays or tables, applicable to gig mills, brushing mills, and other like machinery.

2835 H. Hughes, Homerton, Middlesex. Improved means of rolling or reducing metal rods, bars, or tubes.

Dated September 30, 1869.

2836 A. F. Wilson, Victoria-street, Westminster. Improvements in the mode of, and apparatus for, utilising waste heat from the furnaces of gas retorts.

2837 J. Anderson, Glasgow. Improvements in treating and separating the constituents of maize, and in obtaining oil, starch, spirit, and other products.

2838 J. P. Kerr, and W. M'Gee, Paisley, Renfrewshire. Improvements in winding thread or yarn upon pirns, and in apparatus therefor.

2839 H. Woolf, Houndsditch, City. An improvement in hat brims.

2840 W. Horton, Smethwick, Staffordshire. Improvements in steam boilers.

2841 J. Reeves, Sparkbrook, Worcestershire. Improvements in the bearings of the wheels of velocipedes.

2842 A. E. Fridlander, Coventry, Warwickshire. Improvements in watches and chronometers.

2843 J. Lund, Malsis Hall, near Kildwick, Yorkshire, and E. Townend, Cononley, near Kildwick, Yorkshire. A self-acting means or apparatus applicable to carriages, carts, waggons, and other common road vehicles, whether with four or two wheels, for adjusting the load in ascending or descending.

2844 A. Gaine, Birmingham. Improvements in the manufacture of knobs and furniture for doors, drawers, and other similar objects.

2845 G. Hinton, Ancaster, Wentworth, Ontario, Canada. Driving water-power machinery, so constructed as to economise the water by using over and over again as expended, and driving water wheels of any size with a small body of water, the said improvement being known as Hinton's improved combined water power.

2846 J. Dewe, Toronto, York, Ontario. Improvements in the construction of locks, and in apparatus for indicating the number of times the lock has been opened.

Dated October 1, 1869.

2847 H. L. Bolger, Arthur-road, Brixton, Surrey, and J. Meekin, Milton-road, Dulwich, Surrey. Improvements in apparatus for splitting rocks and other masses.

2848 R. Crickmer, Doris-street, Surrey. An improved mode of, and apparatus for, preventing priming in steam boilers and for regulating the supply of steam therefrom.

2849 F. S. Barff, North Audley-street, Grosvenor-square, Middlesex. Improvements in absorbing and utilising the noxious vapours and gases arising from locomotive engine and other furnaces.

2850 J. Bonn and J. Nitsch, New North-road, Middlesex. An improved instrument to be used for ruling lines on paper and other substances.

2851 J. H. Johnson, Lincoln's Inn-fields. Improvements in screws and in the method of casting the same.

2852 E. A. A. Hugo, Aubervilliers, Arrondissement of Saint Denis, near Paris. Improvements in the manufacture of pressed leather.

2853 R. L. Hickes, Liverpool-street, Old Broad-street, City. Improvements in the construction, arrangement, and fitting of breech-loading firearms.

2854 G. A. Huddart, Brynkir, Carnarvonshire. Improvements in joining or fishing the rails of railways.

2855 W. E. Newton, Chancery-lane. Improvements in sewing machines.

2856 A. J. Ell, Euston-road, Middlesex, and H. Sawah Camden Town, Middlesex. Improvements in apparatus

for indicating and registering the distances travelled by vehicles.

Dated October 2, 1869.

2857 G. S. and H. Whitechurch, Serle-street, Lincoln's Inn-fields. Improvements in stoves and fireplaces.

2858 J. Butcher, Southport, Lancashire. Improvements in fountain pens and penholders.

2859 A. Bodart, Huye, Belgium. An improved balance for ascertaining the specific gravity of liquids, also applicable for other purposes.

2860 W. Edmondson, Manchester. Improvements in machinery for etching or engraving cylinders used for printing and embossing.

2861 T. Buck and G. Messenger, St. Pancras, Middlesex. An improved penholder or reservoir writing instrument.

2862 E. Ludlow, Birmingham. An improvement or improvements in sporting cartridges for breech-loading firearms.

2863 A. Keen, Edgbaston, Warwickshire. A new or improved buckle or tie for fastening hoops or bands of metal around bales of cotton, and for other like purposes.

2864 C. A. Maugin, Boulevart Richard Lenoir, Paris. Improvements in the apparatus used in silvering looking glasses of all sizes.

2865 E. D. Farcot, Boulevart Beaumarchais, Paris. An improved mode of propelling and constructing ships and boats and their accessories.

2866 R. Broadbent, Islington, Birmingham. Improvements in gas governors.

2867 A. Heathorn, Brayford Wharf, Lincoln. Improvements in the preparation of yeast or barm.

2868 J. Reid, Glasgow. Improvements in waterproof coats and leggings.

2869 B. F. Stevens, Henrietta-street, Covent Garden. An improved mode of covering, lighting, and ventilating areas, vaults, and similar underground spaces, applicable also as a footway.

Dated October 4, 1869.

2870 P. R. Hodge, Adam-street, Adelphi, St. Martin's-in-the-fields, C. Hengst, Fulham-road, Chelsea, and N. Wilson, High Holborn. Certain improvements in the manufacture and cementation or welding of steel and iron, iron and iron, and steel and steel together, and in adapting such improvements to various useful purposes.

2871 J. A. Hartmann, Mulhouse, Boulevart de Strasbourg, Paris. Improvements in the process of engraving on metals.

2872 F. Grau, Boulevart Sebastopol, Paris. Improvements in lamp sockets having a double air current for burning paraffin, petroleum, and other mineral oils.

2873 J. Critchley, Manchester. Improvements in the construction of umbrellas, parasols, and sunshades.

2874 G. Rose, Birmingham. Improvements in the construction of annealing pots or pans and muffles, parts of which improvements are also applicable to melting furnaces, heating furnaces, puddling furnaces, and other similar furnaces.

2875 Sir C. T. Bright, Westminster Chambers, Victoria-street. Improvements in electric telegraphs.

2876 C. Mather and W. Rossetter, Salford, Lancashire. Improvements in warping or beaming machines.

2877 F. R. A. Glover, Brading, Isle of Wight. Improvements in anchors, and in the gear for facilitating the weighing and boarding of anchors.

2878 F. F. Villepigue, Brewer's-lane, St. Martin's-in-the-Fields, Middlesex. An improved method of, and apparatus for, piercing or boring holes in rock, mineral, or other material of a similar nature, applicable in tunnel, mine, quarry, and other such work.

2879 J. B. Bradshaw, Whiston-grove, Rotherham, Yorkshire. Improvements in the manufacture of coopers' hoops.

PATENTS ON WHICH THE STAMP DUTY OF £50 HAS BEEN PAID.

2516 D. Imhof
2518 J. Gueunier-Lauriac
2526 A. M. Dix
2530 T. Berney
2533 J. Oetzmann
2534 D. Barker
2540 W. Hope and H. Browning
2539 J. R. Swann
2541 T. Forster
2562 J. Ferrabee
2563 F. W. Kaselowsky
2564 F. W. Kaselowsky
2623 A. H. Brandon
2652 A. Albini and F. A. Braendlin

PATENTS ON WHICH THE STAMP DUTY OF £100 HAS BEEN PAID.

2509 T. Molineux
2736 H. A. Marinoni
2784 J. B. G. M. F. Piret

NOTICES OF INTENTION TO PROCEED WITH PATENTS.

From the "London Gazette," October 5, 1869.

1578 C. J. Foster

NOTICE.—Having received communications from persons residing in the country to the effect that difficulties are occasionally experienced by them in obtaining copies of printed specification from the Patent Office, in consequence of the varying nature of the postage thereon, our readers are informed that upon receipt from them of particulars of the specifications they require, together with a remittance for the cost and approximate postage thereof, we shall be happy to procure and forward such specifications free of all further charge. Sums under Five Shillings may be remitted in postage stamps, for sums above that amount a Post Office Money Order should be sent, payable to ROBERTSON, BROOMAN, and CO., Patent Department, 166, Fleet-street, London, E.C., to whom all communications upon the subject should be addressed.

THE

MECHANICS' MAGAZINE.

LONDON: FRIDAY, OCTOBER 15, 1869.

ON THE LAWS OF TEMPESTS.

THE word tempest may be used to include all such atmospheric disturbances as are known by the terms gale, storm, cyclone, or hurricane. The knowledge collected concerning these meteors has only been systematised within the present century. The rapid extension of navigation and consequent impetus given to commerce rendered it imperatively necessary to grapple with the mysteries of the tempest, to watch and register its signs and details, its characteristics and its results, to generalise these data, ascertain their laws, and found a system or science capable of connecting them in relation of cause and effect. The system so gradually developed may be termed the Laws of Tempests. It is a science elaborated by philosophers, but already it has become an art whereby seamen are enabled to prepare for or to baffle the tempest, or, under suitable circumstances, to reap the full advantage of its force.

Romme, in France, studied the records of tempests in various parts of the world, and arrived at the induction that the wind in storms has a circular character, in short, that they are whirlwinds. Then followed Capper in England, Brande in Germany, and Redfield in New York, who established the law that a tempest is a progressive whirlwind—that the whole meteor moves outward rectilinearly while it is revolving on its own axis. Redfield, indeed, went much further, and stoutly maintained, although he was without means to prove it satisfactorily, that all winds are controlled by the same law of rotation. Dové, in Germany, has succeeded, by the help of the law of gyration, in referring the trade winds, the monsoons, and the so-called variable winds to one common general principle, which Hadley had first applied to explain the origin of the trade winds. Sir W. Reid demonstrated the law of rotation, and established that, in the northern hemisphere, the storm wind turns from right to left, whilst, in the southern hemisphere, it turns from left to right. These, briefly stated, are the fundamental laws of the tempest. The laws relating to the tracks of cyclones in the torrid zone, the curvation of the track near the tropics, and poleward path through the temperate zone, have not been conclusively established, and, as being of less importance, this allusion to them may suffice. Piddington, Thom, Lloyd, Fitzroy, Ballot, Le Verrier, and many others, have, by their investigations, tended to confirm and develope the science of storms. Sir John Herschel has also theorised upon storms with the lucidity characteristic of his writings. He says of cyclones or revolving storms "that they are in the nature of vortices or circulating movements, participated in by masses of air of from 50 to 500 miles in diameter, revolving the more rapidly the nearer the centre, up to a certain distance or radius within which there is a calm. The place of this centre of rotation meanwhile advances steadily along a definite line upon the globe, with a velocity varying from two to thirty or forty miles an hour, or even more."

Tempests are accompanied by great oscillations of atmospheric pressure as exhibited by the barometer. It is during tempests that the mercury in a barometer undergoes its greatest depression, falling with the first part of the storm and rising with the latter. Synchronous observations made upon storm tracks have shown that the pressure at or near the centre of the whirlwind or storm is the least. Hence the barometer falls while the storm centre is approaching towards it, and rises as it recedes from it. To epitomise —the laws of tempests are that gales, storms, and hurricanes are masses of air whirling round a central nucleus while advancing bodily onwards; that the greatest force of wind is at a comparatively short distance from the central nucleus, which is itself a calm; that under the nucleus the barometer is low, being higher the nearer it is to the circumference of the meteor; that they revolve against the sun in northern latitudes, and with the sun in southern latitudes.

Admiral Fitzroy's experience led him to assert that:—"It is sometimes found that cyclones, instead of passing horizontally or parallel to the earth's surface, are inclined at an angle (more or less acute) with the horizontal plane, and we, therefore, feel only parts of them; there may be several such circulations passing or following in the same direction, and revolving similarly, like eddies, with their lower portions, on one side only of the circulating meteor, touching the earth's surface, the other parts circling above our heads, so that we only feel a part of the change, and not the whole of the movement." No gale ever blows upon the coasts of the British Isles violent enough to involve danger without acting upon the barometer, and if the barometric indications were studied and attended to, the disasters to shipping during storms would be lessened. The barometer is a thoroughly scientific instrument, simple in construction, and can be readily used, but it is necessary that its indications should be carefully taught to our seafaring population. How the barometer may forewarn for a coming storm has been well pointed out by Admiral Fitzroy:—"Supposing that a storm is rising, and that a seaman wishes to know where the greatest strength of wind is. If he faces the wind in northern latitude, the centre of the circulation or cyclone will be square to his right; and, in the southern hemisphere, if he faces the wind, the centre will be square to his left; therefore he knows in which direction to go to avoid that part where the greatest strength is, and must shape his course according to circumstances. He can hardly have a simpler rule. His position with reference to distance from the centre, whether it is near the ship or far off, can be ascertained by watching the falling or rising of the barometer, and the way in which the wind shifts. It requires only a sketch upon paper—a rough figure, with an hour or two's observation of the veering of the wind, to know exactly in which direction to steer."

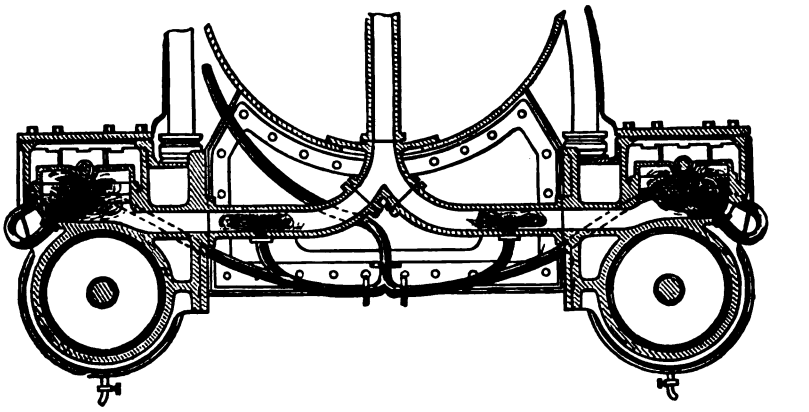
To this we will add a conjecture as to the reason for the barometer being an indicator of storms. Suppose a storm to be represented by a cylinder of air turning on its axis, and advancing (like a wheel) at the same time. The base in contact with the land or sea encounters friction and obstructions, especially from hills, trees, and buildings, &c. From such causes, the motion of the base of the cylinder will be retarded, and, consequently, the upper portion will lean forward. The storm, therefore, may begin at a considerable elevation above a place before the lower part has actually reached the place. This view obtains some support from the fact that the fall of a barometer during the first part of a storm is usually more gradual than the rise of the mercury during the latter part. If the axis were perpendicular to the place of the storm's centre on the surface of the earth, the barometer would there stand lowest. The leaning forward may produce the lowest barometer before the surface centre arrives at the place. From these considerations it may be easily conceived how the barometer may be affected some time before the storm has reached it, and thus afford a warning to those who are acquainted with its use and can appreciate its indications. The barometer is not only an indicator of the coming, but of the progress of storms also. Their approach is usually marked by a fall of the barometer. If the centre of the storm does not pass over the place, the barometer will fall until the part of the storm nearest the centre passes the place, after which it will rise. Dové is of opinion that, in those storms originating in the encounter of polar and equatorial aerial currents, the depression of the barometer is accompanied by a considerable change of temperature also.

The great storms which strike our shore have been considered by some scientific men as meteors having origin in the torrid zone, travelling westerly towards the tropics, there re-curving, and thence advancing north-easterly towards the polar regions, where they are supposed to die out. They are more generally believed to be the result of the encounter of polar with equatorial winds, to be confined to a comparatively small portion of the earth's surface, and to be limited in duration to a few days. Supposing the air over a considerable extent of the earth's surface to become much reduced in weight by copious precipitation of aqueous vapour, and heated by the latent heat given out by the vapour in its condensation, then the normal currents of the temperate zone would tend to restore the reduced pressure. But, in consequence of the rate of rotation of the parallels of latitude being slower the nearer they are to the earth's pole, the polar current has a westward tendency, and the equatorial an eastward tendency. In this way they act as a mechanical couple upon the area of low pressure, and produce a whirlwind which must have an invariable direction of rotation. Meteorologists assert that the northern portion of each whirl maintains the distinguishing features of a polar wind, namely, heavy, cold, and dry air, but this has never been shown to be the case for a number of consecutive whirls, nor has it been satisfactorily explained. The cyclone once formed, the area of low pressure must rapidly be filling up, and the passage of the polar wind to the south, and the equatorial to the northward, must soon restore equilibrium of pressure, temperature, and humidity and the poleward and equatorward portions of the whirl, at each rotation, must exhibit less and less difference of these characteristics. Although the whirlwind character of every tempest which strikes our shores is borne out by the official daily observations, yet prejudice and misapprehension still prevail, for many self-opinionated seamen may be met with who deride or deny the laws of tempests, and who reckon as nothing the experience of hundreds of navigators, which affirms they have undoubtedly been the means of preserving many a ship from disaster.

COUNTER-PRESSURE STEAM AS A LOCOMOTIVE BRAKE.

THE name of M. Le Chatelier has long been familiar to the engineering profession in connection with investigations bearing upon the economic working of the locomotive engine and other important matters. He now comes before us as the practical exponent of a principle which has received attention for some years past at the hands of several engineers. This is no less than enabling the driver of a locomotive, when reversing steam, to utilise the work done during the inverted action of the engine for regulating and checking the speed of trains. In other words, M. Le Chatelier has perfected a steam brake, and, although it comes to us as a novelty, it has already been applied to nearly 3,000 locomotives on the continent. With regard to the attempts which have from time to time been made to effect this object, we may first mention that in France M. Beugniot and in Austria M. Zeh have experimented with closed exhaust nozzles; the one so as to cause a vacuum

M. LE CHATELIER'S STEAM BRAKE.



behind the piston, the other to establish a pressure behind the piston, and thus avoid drawing in the heated gases of combustion from the smoke box. Early in 1865 Mr. De Bergue experimented with a system of brake by compressed air, so arranged as to prevent the introduction of the fixed gases into the boiler. This system gave satisfactory results for short runs of two or three minutes, but did not answer when the action was prolonged. In July, 1865, M. Le Chatelier directed experiments to be made on this important subject on an entirely new principle, and his ideas have been put in practice with complete success both in France, Spain, and Germany. The principles, mode of application, and the results obtained from M. Le Chatelier's experiments are embodied in a small treatise,* which has lately reached us, and from which we take the following particulars of this important invention.

The principle as worked out by M. Le Chatelier is exceedingly simple, although of course perfection has not been arrived at without long and anxious study accompanied by careful experiment. It simply consists in leading a small tube from the boiler to the bottom of the exhaust pipe near the cylinders. Through this tube from eight to forty pounds of hot water are delivered per minute, under the pressure in the boiler, and this water is instantly converted into a fine spray by contact with the hot metallic surfaces of the cylinders and pistons. While cooling them, and absorbing the heat produced in the motion of the parts, the steam produced acts not merely as an elastic brake, but it may be made to cause a discharge from the blast pipe sufficient to keep out any gases from the smoke-box. The apparatus—if so simple an arrangement can be so called—may, therefore, be said to consist of a pipe from 1in. to 1¼in. diameter, and a common tap; it is as simple as the principle itself. We give in the annexed engraving a view of the arrangement, from which it will be seen that the tube communicates between the boiler and the exhaust pipe, the supply being regulated by a distributing cock. Our illustration represents two arrangements. In the one the insertion is made on the branches of the exhaust tube, and the wet vapour has two distinct ways to traverse to reach the cylinders, viz., the part of the pipe near the cylinders and the admission ports. This wet vapour does not get into the cylinders until after the steam, more or less dry, has been discharged from them at the end of the expansion, nor until that at the end of the cushioning has returned. If there be excess of injection water, it is projected through the blast pipe nozzle by the funnel. In the other arrangement the insertion is made under the slide valve itself in the side of the discharge port. In this case the wet vapour has only to traverse the passage to the ports; one part enters directly at the moment of induction, the other mixes with the discharged steam, returns in part to the cylinder, and goes off in part with it to the nozzle.

In the practical working of this brake it is proved by experience that, for equality of injection, much more water is projected by the funnel, and falls in rain on the engine, in the first arrangement than in the second. This arises from the greater quantity of steam generated in the first arrangement; whereas in the second the water is held in suspension by a greater quantity of steam. The process is found to act almost simultaneously, three or four seconds being ample after letting on the water jet, and without even opening the regulator, to make the change from full forward gear to full backward gear.

We need not here insist upon the value and importance of M. Le Chatelier's invention—they are self evident. This system of working counter-pressure steam places the control of the speed of the train directly into the hands of the driver, giving him a means of instantaneously using all the load on the driving wheels as a brake, without danger to himself or stoker, and with little physical effort. It gives a higher degree of security against collisions and over-running stations than has hitherto existed, and greatly facilitates all shunting operations. It economises rails, by dispensing in a great measure with the use of the brakes of the tender and brake vans. It economises wheel tyres and grease. It allows of the number of brakesmen being permanently reduced. Again, it has to scientific engineers the interest of being an illustration of the dynamic theory of heat; the work of retardation being converted into heat, which is in great part sent to the boiler, instead of being wasted in abrading rails and tyres, heating pistons, stuffing boxes and wheels, and thereby wasting grease and oil. Finally, the apparatus can be applied to any construction of locomotive at small cost, and without any other alteration of the engine than that of fixing the apparatus upon it. Unquestionably, M. Le Chatelier deserves the gratitude of all railway companies for this valuable contribution to the practical development of the locomotive engine.

* "Railway Economy. Use of Counter-pressure Steam in the Locomotive Engine as a Brake." By M. L. Le Chatelier, Ingenieur en chef des mines. Translated from the Author's manuscript by Lewis D. B. Gordon, F.R.S.E. Edinburgh: Edmonston and Douglas. 1869.

THE HULL BOILER EXPLOSION VERDICT.

The inquest held in consequence of the steam boiler explosion which occurred at Messrs. Hodges' seed-crushing mill, Holderness-road, Hull, on the 16th ult., marks an era in such proceedings. It shows that coroners and jurymen are beginning to realise the difference between a purely uncontrollable accident and an occurrence which by care and forethought might have been prevented. The case before us involves a most important alteration in the form of the verdict. The jury adopted the term "no malice aforethought" instead of the old stereotyped word "accidental." The use of the word "accidental," although explosions have occurred from clearly preventible causes, is most contradictory, and has done a great deal of harm. The recommendation that the word "accidental" should be disused and the term "no malice aforethought" substituted, was made by Sir William Fairbairn's boiler explosion committee at the last meeting of the British Association, at Exeter, and the present is the first occasion upon which it has been adopted. Its general use would certainly prove highly advantageous, and we hope to see it adopted in future wherever verdicts of this nature have to be found. The fundamental object of a coroner's inquiry in case of a sudden or violent death is to determine whether that death was occasioned by personal malice or not. It may be legally correct for the jury to return a verdict of "accidental death" from a steam boiler explosion, though the boiler may have been so worn out that in an engineering and a common sense view the explosion was no accident at all. Thus the jury use the word in one sense, but the public accept it in another, and the term is taken to be an exoneration of the owner of the boiler. We think, however, that the obligations of juries will be fulfilled, and at the same time the prevention of steam boiler explosions promoted, if juries, instead of returning a verdict of "accidental death," would state that they consider there had been "no malice aforethought." The applicability of the term in the present case is clear from the report made by Mr. L. E. Fletcher, chief engineer of the Steam Users' Association, to the coroner on the above explosion, and which will be found on another page. We do not overlook the fact that juries have a third course open to them, which lies between the announcement of "accidental death" and that of "wilful murder." They have the power of committing owners of boilers for manslaughter, a power which, in many cases, they are bound in discharge of their duty to exercise, and that, too, much more frequently than they do. The task, however, of committing a boiler owner for manslaughter is frequently an invidious one for a coroner's jury, and in practice verdicts of manslaughter are rarely brought in by them. If, however, the practice of introducing the term "no malice aforethought" were fully carried out, coroners' juries would be extracted from an unpleasant position, and the truth with regard to steam boiler explosions would be more fully and freely spoken. We are glad the Hull jury have taken the initiative in the matter, and trust their example will be widely followed. It is one step in the right direction towards the protection of life and property from the dire results of parsimony and carelessness.

DR. LIVINGSTONE.

Our last impression contained a telegraphic notice from Falmouth, which was gladly read by many, as it gave hopes of the safety of Dr. Livingstone. The following is the foundation for the statement. A Miss Jones, who has been four years at the Central African Mission with Bishop Tozer, landed with a Mr. and Mrs. Lea at Falmouth on Wednesday morning, October 6, from the Hamburgh ship "New Orleans," after a very protracted voyage of more than seventeen weeks from Zanzibar, and proceeded same day to Plymouth, to the house of a friend to pass the night. Mr. Lea accompanied her from the station, and in the course of conversation Dr. Livingstone's name was mentioned. Miss Jones stated no one believed him to be dead; at least when they left (June 6) some natives knew quite well there was a white man up country, and that would probably be Dr. Livingstone; and in conversation Dr. Reik's

name was mentioned. The Plymouth friend appears to have conveyed the substance of the conversation to a local paper, and hence the telegram.

The circumstance could not, of course, fail to attract the attention of the veteran explorer's old friend Sir Roderick Murchison, from whose pen a few lines have appeared on the subject. Sir Roderick is naturally unwilling to throw any doubt upon the news recently announced as to the arrival of Dr. Livingstone on the eastern shore of the Lake Tanganyika, but he states that this is only one of the many rumours regarding the great traveller which have from time to time been brought to Zanzibar. Sir Roderick has recently received two letters, one through the Admiralty, by Commodore Heath, of the East African station, and the other from Dr. Kirk, the British political agent at Zanzibar, both dated the 31st of August, and both stating that an Arab had arrived that same day with a letter from his brother, the Governor of Unyanyembe, in which it was stated that a servant of the Governor had seen "the white man" at Ujiji, on the Lake Tanganyika. According to Dr. Kirk's estimate, four months must have elapsed since the man who brought the information left Ujiji. If this news should be correct it would certify that the illustrious traveller was in safety at the end of last April. But so long as no direct news from Dr. Livingstone himself has been received, it will naturally be surmised that this last report may have no better foundation than the numerous preceding rumours. It is, however, gratifying to state that if the news rests upon a true foundation our suspense will soon be relieved, for the same letter informed Sir Roderick that a caravan from Ujiji was expected to reach Zanzibar in a month.

Since Sir Roderick Murchison's letter was penned, the following important and welcome telegrams have been received:—

BOMBAY, OCT. 6.

Dr. Kirk has received a letter from Dr. Livingstone, dated Lake Banglewo, 8th of July, 1868, saying:—

"I have found what I believe to be the sources of the Nile, between 10deg. and 12deg. south."

Dr. Livingstone was in good health and spirits when the letter was despatched.

BOMBAY, OCT. 11.

A letter of Dr. Kirk to the Bombay Government has been published, stating that a caravan which has reached Zanzibar reports Dr. Livingstone's arrival at Ujiji. The road between the coast and Ujiji was open and safe. Small parties of men and another caravan were expected.

THE WINTER INSTRUCTIONS OF THE GAS REFEREES.

ANYONE who has watched the gradual development of an infant's powers, who has seen it execute wild movements and make wide snatches in the air in the endeavour to lay hold of something just before it and immediately within its grasp, until by degrees it acquires power of going straight to the desired object, will be able to form an idea of the progress exhibited in each successive publication of the Gas Referees. By degrees the referees are acquiring the power of instructing gas examiners in the performance of duties which the examiners perfectly understand; and this, as is the case in the infant's progress, is partly the result of the development of the imitative faculty. We must congratulate them on the advance made, while we point out to our readers in what it is shown. In the first place, the referees appear to have discovered the absurdity of making two experiments for sulphur and taking the mean result to represent the amount in the gas. They now order but one experiment to be made. In operating upon the condensed liquid also, they seem to have found that the use of the large quantity they formerly directed involved a waste of re-agents, so they now order but half that quantity to be used. So, too, in making the calculations of illuminating power, they have become convinced that the roundabout method they first prescribed involved what we may call an unnecessary waste of figures, so they have adopted the short and simple method followed by Mr. Heisch, which, in their reply to that gentleman's report, they by implication condemned. These things show teachableness and exhibit progress, and therefore deserve recognition. There is one matter, however, in which the referees seem to make no advance. They have not yet fixed upon the amount of sulphur to be allowed. No doubt this is a difficult point to settle; but the referees have before them the returns of three companies, and those of the Great Central Company show them how far gas may be purified from sulphur by ordinary processes and appliances. Surely from these data they might fix upon some standard, which they still have the power to vary from time to time; or they might at once adopt the old standard of twenty grains in 100ft. They have advertised their willingness to examine any new processes for purifying gas from sulphur. Several no doubt will be submitted to them; they will require time for examination and experiment, and after all may turn out of no value. In the meantime the referees expose themselves to much invidious comment by not acting on information they have now before them.

PHOTOGRAPHY.

SCIENTIFIC PRINCIPLES APPLIED TO PHOTOGRAPHY—THE STRUCTURE OF COLLODION FILMS—THE ALKALINE WET PROCESS—ETHNOLOGICAL PHOTOGRAPHS—MR. MUMLER'S PROCESS.

THAT great discovery of modern science, the law of the conservation of energy, which demonstrates that force can neither be created nor destroyed, but only turned into particular channels or modes of manifestation by man, may be of some little use when applied to photographic experiments. The force which sets up molecular disturbance on the sensitive plate is wave motion, and it probably acts by setting up a motion of separation between the atom of iodine and the atom of silver. This much is certain, namely, that the energy of radiant light is transformed into the energy of molecular disturbance, whatever the precise nature of that disturbance may be. Any chemical rays, therefore, which pass through the sensitive film and the glass plate without doing work represent so much lost power, which lost power must either necessitate longer exposure to get a picture, or be a cause of less energetic and less intense development. Nearly all wet and dry plates used in photography permit some of the actinic rays to pass through the film. These rays thus wasted often do a certain amount of positive harm in addition, for the back surface of the glass often reflects them once more upon the film, so as to produce a blurred and indistinct picture. In practice, wet red blotting paper is often placed in optical contact with the back of the glass plate, to prevent this blurring by reflected light. Manifestly, then, the most perfect films are those which absorb nearly all the chemical rays, and as few such films are employed in photography, except in rare instances, when they are obtained by accident, there is plenty of room for experiment in this direction. Plenty of yellow iodide of silver in the film is chemically more opaque than plenty of bromide of silver, and this is another reason why photographers should once more give iodized collodion a trial, as recently recommended in this journal. In dry plates, the use of deeply coloured organifiers well deserves a trial.

Having obtained a film which utilises all the mechanical power of the chemical waves of light, it is desirable that every part of the sensitive surface should come into immediate contact with the developer when it is applied. When bromide of silver is held in suspension in a very weak solution of gelatine, and some of this solution is allowed to dry upon an accurately levelled glass plate, a rough film results, held to the plate only by a mere trace of gelatine. Such a film gives an intense picture very rapidly when an alkaline developer is applied. But if the bromide of silver be held in suspension by a very strong solution of gelatine, and the same experiment tried, no picture whatever can be developed; in fact, the particles of bromide of silver might as well have been imbedded in the solid glass of the plate. Again, a wet sensitized collodion plate developes readily, but the same plate dried requires longer exposure and tedious development. Wet collodion films are soft and pulpy, but when once they have been dried they form a tough skin, and never return to their former state. Hardwich has pointed out that iodide of silver is much more sensitive to light in the interstices of wet collodion than in the interstices of wet paper or other medium, and he attributes this sensitiveness to the loose state of cohesion in which it is held in wet collodion. It is easy, therefore, to see that a tough sample of collodion may allow development to proceed more rapidly on the upper surface of the film than on the surface in contact with the glass. There is, in fact, ocular evidence that chemical action proceeds with unequal velocity at the two surfaces of collodion films, because pictures which appear to have been quite fixed by cyanide of potassium, when viewed from the one side, are often seen not to be fixed when viewed through the glass from the other side. When a developer does not at once penetrate the film, a picture of low intensity is probably the result. This reasoning points to the conclusion that the best collodion films should let no actinic rays pass through them, and should be of a soft and spongy and not tough consistency. Other qualities, well known to photographers, are likewise necessary in good collodion. There is plenty of room for experiment in this direction by some good photographer versed in the manufacture of collodion, who should keep these principles in view, and ascertain the nature of the structure of the film given after sensitizing, by each of his samples of collodion, the microscope being the medium of examination. Very probably, in the best dry plate processes of the future, collodion will be entirely abolished; at all events, a layer of dry bromide of silver, containing a trace of organic matter, and not imbedded in a collodion or any other skinny film, gives a picture which comes out under the alkaline developer with marvellous facility.

Mr. Sutton's new alkaline wet process, as set forth in his pamphlet recently reviewed in these columns, is scarcely receiving fair treatment at the hands of many of the photographic journals. Instead of trying the process to see whether it possesses the merits claimed, they content themselves with criticising point after point of the process, and saying that each point "is not new." But what does this matter? As a whole, it is new, for where has any process been published wherein all the chemicals and baths are alkaline and neutral, and the alkaline plates thus produced are used wet? Where also (assuming Mr. Sutton's statements to be accurate) has any alkaline wet process been published which gives twice the rapidity of the best wet free nitrate plates? The question at issue is, "Does the process possess all the advantages claimed by the inventor?" If so it will be of the greatest value in instantaneous photography, but in no other branch is it likely to compete with the ordinary wet process. Mr. Sutton, by an injudicious course of action in the matter of the sale of the collodion, has raised a barrier which will prevent many photographers from trying his process, and this throws the onus of the proof of its merits for the most part upon himself. If the process is so much more rapid than the wet one, he is able to take pictures of street scenes and moving figures and vehicles with much more rapidity than anybody has done yet. He should, therefore, take some street views, and send them, negatives and all, for examination at one of the London photographic societies. If the process has all the rapidity stated the street views taken instantaneously by Blanchard and others will be thrown into the shade, and those who are somewhat abusing Mr. Sutton, rather than investigating the merits of his process, will be silenced. As yet, nothing in the way of instantaneous pictures by Mr. Sutton's process has been brought publicly under the view of London photographers, and until these pictures do make their appearance the claims made for the process are not proven.

The Ethnological Society, under the presidency of Professor Huxley, is making arrangements to take photographs of specimens of all races of men in all parts of the globe. Such photographs should be taken before a background, ruled off by plainly visible lines into spaces 6in. square, so that all the pictures shall show the dimensions of the individual photographed, and be directly comparable. The "sitter" should stand upright, and be in contact with the background. When photographs of such value are collected from all parts of the earth, it is ten thousand pities that they should be printed on paper by the ordinary silver process, to fade away in the course of years, and never perhaps to be replaced, as many tribes of savages are dying out before the progress of civilisation. The negatives should all be sent to England, and be copied by a permanent carbon process, or upon collodion films, cemented between two plates of glass with tough Canada balsam. It is very much to be regretted that the Ethnological and the Anthropological Societies do not sink their petty differences and unite into one strong body, to carry on their work with more power and efficiency.

The "Illustrated Photographer" has raised the question whether the alleged spirit forms in Mumler's pictures had distinguishable features. Some copies reached England, and were examined by three photographic experts. Some of the pictures had recognisable features, and some of them had not. In one of them a lady draped in white stood behind Mr. Livermore, the New York banker, and from behind held a bunch of flowers down in front of his dress. This form had recognisable features, which Mr. Livermore swore to be those of his wife, who, he said, had been dead some time, and had never been seen by Mumler. This picture, more than any other, procured Mumler's acquittal, as photographers cannot do the same thing without collusion on the part of the sitter. A very bad copy of this picture, without distinguishable features, was published in the "Illustrated Photographer," but the original had features plain enough to fit one person only, and not anybody conjured up by the imagination of the observer.

TELEGRAPHIC NOTES.

THE storage of the Anglo-Indian cable on board the "Great Eastern" progresses rapidly and satisfactorily, there being at the present time upwards of 1,700 miles coiled in the iron tanks. The filling of the main tank was completed on Tuesday last, and the tank was fastened down the same day. It contains about 1,100 miles of the cable. The after tank at present contains over 600 miles, and the workmen are now busily engaged in completing it; after which the fore tank, which is at present empty, will be taken in hand. The tests which pass daily through the wire show it to be in excellent condition. The bottom of the great ship, during the past few weeks, has been cleaned by divers from the diving smacks "Sealark" and "Ann Elizabeth,', of Whitstable, under the superintendence of Mr. John Pierce, of that town. It is the first occasion of the bottom of this great vessel being cleaned by divers. The bottom of the ship was in a very foul state, mussels having gathered on her in some places more than a foot thick. After the bottom was cleaned, it was found that the iron was very little rusted, and the surveyors from London have expressed their satisfaction at the able manner in which the work of cleaning has been performed. It is estimated that 50,000 gallons of mussels and rubbish were removed from the ship beneath the water line. The utmost exertions are being used by Captain Halpin, Mr. Beckwith, and the officers and men under their command to get the "Great Eastern" completed for sea by the 23rd inst., the date fixed for her departure from Sheerness *en route* to Aden.

We recently noticed the intention on the part of an American Telegraph Company—the Western Union—to apply to Congress to buy them up and carry on the business upon our new plan. In view of this, the following particulars relating to American telegraphs may prove interesting. The first line of telegraph in the United States, which was between Washington and Baltimore, was laid down in 1844; but the experiment was so unsuccessful that the Postmaster-General, in his report of 1845, expressed his opinion that the revenue could never be made equal to the expenditure under any rate of charges which might be adopted. The Western Union Company alone now works 52,099 miles of line, and 104,584 miles of wire, this company having amalgamated by far the larger portion of the telegraphic lines of the United States. Mr. Orton, the president of this company, has issued an elaborate report, in which he estimates the aggregate for all the United States' companies as follows:—Miles of line, 73,088; miles of wire, 130,695; number of stations, 5,029. Of his own company, he states that its net earnings for the past three years have been 8,161,645dol., or 2,720,548dol. per annum, which is over 6¼ per cent. upon the capital. Its gross receipts this year have averaged 600,000dol. a month, its expenses about 375,000dol. The aggregate amount of news delivered to the newspapers of the United States by the lines of this company during the past year was 369,503,630 words, for which it received 883,509dol. currency, being at the rate of two and three-tenths mills per word. This immense amount of matter was not transmitted to each paper separately, but, through a combination of wires only possible to a vast system like this, was sent to a large number of places simultaneously with only one transmission.

A steamer has been for some time at Valentia with the necessary appliances for lifting the Atlantic cable of 1866 with a view to repair it. As yet the efforts which have been made have not been successful, and, on Monday week, an accident occurred which will render the operations more tedious and difficult. The cable was grappled and brought up, but, while the crew were hauling it in, it broke, and fell again to the bottom, 150 fathoms deep. This is the fifth time it has been broken.

We understand that Mr. Scudamore and several officials from the General Post Office and the Telegraph Office were in Newcastle-on-Tyne last week, and met the principal postmasters in the district to impart instructions and make inquiries as to requirements of the two north-eastern counties of Durham and Northumberland in anticipation of the telegraphs being transferred to the Post Office in January next.

A deputation from the West India and Panama Telegraph Company (Limited)—Mr. M'Gregor, Mr. Chambers, and the engineer of the company, Sir Charles Bright—waited on the First Lord of the Admiralty, on Wednesday, with reference to telegraphic communication with all the British Colonies in the West Indies and their connection with North and South America.

The number of messages through the French Atlantic Cable during the week ending October 9 was 982, the cable charge upon them being £2,600—showing an increase of £890 over those of the preceding week, partly to be accounted for by the delay caused to the messages of the Atlantic Company through damage to the land lines with which they are in communication.

NOTES ON RECENT DISCOVERIES IN SCIENCE AND THEIR PRACTICAL APPLICATIONS.

NEW USES FOR GLYCERINE—SUBSTITUTE FOR WASHING SODA—USE OF GRAPHITE IN THE BESSEMER PROCESS—MODE OF MAKING A QUICKLY DRYING PAINT—NEW WAY OF REMOVING THE GUM FROM SILK—HOW TO MAKE PAPER HATS.

WHAT will be done with wine next, with the view of improving it, is hard to say. The last notion is adding glycerine to it. This body is a natural product of the fermentation of grape sugar, and is present, though in extremely small amount, in all natural wines; but Herr Kolb proposes to add from one to three per cent., which, he says, and he is probably right, will reduce to the smallest possible limits the tendency to change which all wines from their inner nature possess. It is hardly necessary to say that the author of this suggestion directs perfectly pure glycerine to be employed. Certainly that disagreeable-smelling, acrid-tasting article commonly sold is not likely to improve the flavour of a wine, or assist in producing a fruity port. Glycerine is said to be largely used by the compounders of artificial champagnes and also by liqueur makers.

A German scientific journal recommends laundresses to use hyposulphite of soda in place of common washing soda. It does not attack the fabric in any way, and at the same time exerts some bleaching action, which greatly improves the appearance of linen and calicoes.

In the Bessemer process very good results are obtained with grey pig iron, but far inferior with white pig. The difference in the two irons is mainly in the proportion of graphitic carbon they contain. Hence it has occurred to Herr Brunner to make use of some graphite in the first stage of the Bessemer process, but the results do not seem to have been very satisfactory. Better, it would seem, are obtained by sending wood charcoal dust, with the blast, according to the plan of Herr Stockher.

We recently noticed the varnish made by the solution of shellac in ammonia, and had occasion to observe that a varnish could also be made by dissolving the same substance in borax. A solution of this kind, which forms a strong and quickly drying varnish, can be made in the following way. Twelve parts of shellac and four parts of borax are added to 100 parts of water; heat is carefully applied, while the mixture is continually stirred, and soon a complete solution is obtained which is colourless or brown according to the colour of the shellac employed. This solution, as we have said, forms a varnish perfectly impermeable to water, and not acted on by the atmosphere. It can be used with oil paints to make them dry quickly by adding an equal part of the varnish with a little turpentine to the oil colour, and rubbing them together until a homogeneous fluid mixture is obtained. This mixture dries in from ten to fifteen minutes, and hence only a small quantity must be prepared at a time.

Dyers have been in the habit of removing the gum from the surface of raw silk by boiling with soap. A French patent makes known the fact that the end is more easily and cheaply obtained by the use of ammonia. To a kilogramme of silk they use ten litres of water and from 250 to 500 grains of ammonia, according as the silk is white or yellow and hard. The silk is kept in the solution heated to 80deg. or 90deg. C. for an hour, and then it is boiled for half an hour. By this treatment silk loses from 22 to 28 per cent. of weight. To finish the process it must be rinsed in a boiling bath containing 1 or 2 per cent. of soap, which bath may be used many times over. The carbonate may be used in place of liquid ammonia.

Paper hats may some day be in vogue here; they have been introduced in America, and this is how they may be made. Take a straw hat of the size and shape you require, cover it inside and outside with wax, do the wax over with plumbago, and then take an electrotype mould. Continue the deposition of the copper until you have a mould sufficiently thick to stand the pressure to which it will be presently exposed, that is, after the pulp has been poured in. The little details which it will be necessary to attend to in this manufacture are not supplied to us, but they will be readily seen and understood. The paper hat is of course the exact image of the straw one, and may be coloured to represent its original. It can be made waterproof by ordinary means and will be cheap and durable.

ON Saturday Edwin Goddard, one of the employes at Mr. Soper's engineering works at Vauxhall, travelled on a bicycle of his own make from the metropolis to Newbury, in Berkshire, (a distance of about 60 miles), in 10 hours. Goddard, whose parents reside in Newbury, left Vauxhall at 6 o'clock a.m., took breakfast at Hounslow, and dined at Reading, having accomplished nearly 40 miles of the journey. After a short rest he again mounted the machine, and safely reached his destination. The weather on Saturday was unusually warm for the time of year, but Goddard's physical powers are good, and he completed the journey without the slightest inconvenience to himself.

SIR JOHN FRANKLIN.

THE document respecting the fate of Sir John Franklin, which is reported to have been picked up on the Californian coast at San Buenaventura, August 30, was enclosed in a worn-out, battered-looking bag, made of sealskin, and hermetically sealed. The paper was 13in. by 10in., and much mutilated. Besides the statement in six commercial languages requesting the finder to forward it to the nearest British Consul, or to the British Admiralty, the paper contained the following, which is a transcript of its contents, as well as they can be deciphered :—

Her Majesty's ships "Erebus" and "Terror, May 28, 1847. Wintered in the ice in lat. 70deg. 5min. N., long. 98 deg. 23min. W.

Having wintered in 1845-6 at Beechy Island in lat. 74deg. 43min. 28sec. N., long. 91deg. 39min. 15sec. W., after having ascended Wellington Channel to lat. 77deg., and returned by the west side of Cornwallis Island.

Sir John Franklin commanding the Expedition. All well.

Party consisting of two officers and six men left the ships on Monday, 24th May, 1847.

GRAHAM GORE, Lieutenant.

CHARLES F. DES VOEUX, Mate.

Around the margin and on the available space outside the printing the following is inscribed :—

Her Majesty's ships "Erebus" and "Terror" were deserted on the 22nd of April, five leagues N.N.W. of here, having been last seen September 12, 1846. The officers and crews, consisting of 105 souls, under the command of Captain F. R. M. Crozier, landed here in lat. 69deg. 37min. 42sec. N., long. 98deg 41min. W. Sir John Franklin died on the 11th June, 1847, and the total loss by death in the Expedition has been to this date nine officers and fifteen men.

F. R. M. CROZIER, Captain and Senior Officer.
JAS. FITZJAMES, Captain, Her Majesty's ship "Erebus."

And start on to-morrow, 26th, for Back's Fish River.

Other intelligence also comes to us from the Arctic Sea, through the "Times'" correspondent in the United States. Mr. C. F. Hall, an American explorer, who for five years past has been making land journeys through the Arctic regions, has returned in a whale-ship to New Bedford, Massachusetts. He brings with him several Esquimaux, and reports some interesting intelligence about Sir John Franklin's party. None of them, he states, ever reached Montreal Island. He saw natives who were the last to look upon Crozier and his party. Mr. Hall brings with him the remains of a young man belonging to the expedition, and also numerous relics. He promises a full account of his journeys, and also says he will return to the Arctic regions next spring and further prosecute his explorations. To Mr. Henry Grinnell, of New York, the thanks of the public are due for furnishing Mr. Hall the means to make these discoveries. Another American exploring expedition, that of Hayes and Bradford, returned on September 27 to St. John's, Newfoundland, so that for a time accounts of Arctic explorations will be numerous.

THE "HINDOSTAN."

YESTERDAY week the new screw steamship "Hindostan," built and engined by Messrs. Day and Co., of the Northam Ironworks, Southampton, for the Peninsular and Oriental Company, was taken to Stokes Bay for a trial of her speed on the measured mile. There was a moderate easterly breeze blowing, with a smooth sea, the barometer standing at 30·55. The true mean speed attained was 14·392 knots per hour, with a 30lb. pressure of steam, vacuum 21, and the engines making 55 revolutions per minute. The engines, which are of 600-horse power nominal, indicated 3,194 during the trial. She had on board a total weight, of coals water, and stores, of 734 tons, and her draught of water was 16ft. 2in. forward, and 17ft. 8in. aft, mean draft being 16ft. 11in. The machinery worked with the greatest ease thoughout the day, and we are able to congratulate the builders on the successful results of the trial. The following are the leading dimensions of the "Hindostan":—Length between perpendiculars, 349ft. 10in.; length on loadwater line, 344ft. 4in.; length over all, 382ft. 8in.; breadth moulded, 42ft. 3½in.; depth of hold, 33ft.; tonnage, builders' measurement, 3,086 tons; and engines of 600-horse power. She has accommodation for 176 first and 55 second-class passengers, and will be able to carry 800 tons of coals and 1,400 tons of cargo. The hull of the vessel is built of the best Staffordshire iron below the water-line and steel above. The "Hindostan" was in charge of Captain Robert Curling, who is appointed as her commander, and she will shortly be dispatched to India, where she is to be employed in the company's mail service.

ROYAL NATIONAL LIFE-BOAT INSTITUTION.

A MEETING of the above institution was held on Thursday at its house, John-street, Adelphi, Mr. Thomas Chapman, F.R.S., in the chair. There were also present—Admiral Sir W. H. Hall, K.C.B., F.R.S., Mr. W. H. Harton, Sir Edward Perrott, Captain Richards, R.N., F.R.S., hydrographer of the Admiralty, Captain de St. Croix, and several other gentlemen. The secretary having read the minutes of the previous meeting, rewards amounting to £218 were voted to pay the expenses of different services of the lifeboats of the institution on the occasion of shipwrecks during the recent heavy gales. The city of Bristol lifeboat, the "Albert Edward," stationed at Padstow, rescued four men from the lugger "Isabelle," of St. Malo. The "Arundel Venables" lifeboat, at Arklow, saved 21 men from the screw steamer "Hellenis," of Dublin. The lifeboat "Jane," at Worthing, brought ashore the abandoned smack "Active," of Selsey. The lifeboat "Cheltenham," at Burnham, saved three men from the schooner "Prudence," of Watchet, and assisted into Bridgewater a distressed Dutch schooner and her crew. The "Willie and Arthur," tubular lifeboat, at New Brighton, saved 18 persons from the barque "Empress," of Prince Edward's Island. The "Havelock" lifeboat, at Fraserburg, North Britain, saved seven men from the steamship "Viking," of Dundee. The lifeboat "Western Commercial Traveller," stationed at Cadjwith, had also assisted the disabled brig "Phillis and Mary," of Blyth, and her crew of eight men into Falmouth Harbour. The "Quiver" lifeboat, at Margate, assisted to save the schooner "Lady Anne," of West Hartlepool, and her crew of five men. The "Christopher Ludlow" lifeboat, at Dungarvon, took the yacht "Emetic," of Dunmore East, and her crew of three men, safely into harbour. The "Appleyard" lifeboat, of Saltburn, brought one man ashore from the schooner "Bonnie Lass," of Wick. The Wexford large lifeboat, the "St. Patrick," rendered valuable assistance at the wreck of the ship "Electric Spark," of Boston, United States, and saved 21 men. Fourteen other lifeboats of the society also went out to distressed vessels during the past month. Altogether the institution's boats saved 94 lives in that period, besides five vessels.

The second service clasp was presented to Richard Jones, chief boatman of the coast-guard at Tramore, Ireland, and coxswain of the lifeboat placed there, on the occasion of his retirement from that station, in acknowledgment of his general gallant services in saving life from shipwreck. The thanks of the institution, inscribed on vellum, were also voted to John Cummins, the coxswain of the Arklow lifeboat, for his skilful and highly meritorious services in that boat. Various rewards were also granted to the crews of different shore boats for saving life from wrecks on our coasts. The recent services of the "Hans Busk" lifeboat, at Ryde, were alluded to in terms of admiration. The benevolent donor of the boat has long been known as a warm and steadfast friend of the lifeboat cause. Payments amounting to upwards of £3,000 were ordered to be made on various lifeboat establishments. The Emperor of Austria had presented a donation of £25 to the institution, and various honorary rewards to the coxswain and some of the crew of the "Appledore" lifeboat, in acknowledgment of the services rendered on the occasion of the wreck of the Austrian barque "Pace" on December 28 last. A benevolent gentleman signing himself "Benjamin" had also sent the society a liberal contribution of £100. A legacy of £1,800 had been received from the executors of the late Mrs. H. Richardson, of Greenwich, for the purpose of forming and permanently supporting a lifeboat station. The late Mr. William Sinclair, of Sowerby, had also bequeathed to the institution £200 free of duty. The committee expressed their sincere regret at the decease of Mr. Alexander Botefeur, who had been for many years an active member of the committee of management of the

society. He had also been a munificent supporter of the lifeboat cause. New lifeboats had recently been forwarded by the institution to Salcombe, Sidmouth, Porthonstock, Mevagissey, Llandulas, Port Isaac, Duncannon, and the Isle of Whithorn; and at each place demonstrations had been organised to welcome the boats to their stations. Reports were read from the inspector and assistant inspector of lifeboats to the society on their recent visits to different lifeboat stations. The proceedings then terminated.

ORNAMENTING GLASS.

Mr. George Rees, of Holloway, has lately patented an invention for producing ornaments or devices by vitrifying pounded glass upon glass and glazed ware, or by cementing together fragments of coloured glass or glazed ware by vitrifying a layer of pounded glass on to the fragments. The glass, after it is pounded, is sifted through sieves, the meshes of which correspond to the sizes of the particles of glass to be used on the surface of the glass or glazed ware. The *modus operandi* is as follows:—Take a sheet of glass and prepare the surface by brushing a gummy or other adhesive liquid thereon. Then sprinkle pounded glass over the gum, which adheres to it. The glass thus prepared is placed in a furnace, or under heat in any suitable manner, in order to vitrify the pounded glass upon the surface of the sheet glass. The pounded glass may be of one or a mixture of colours, or the sheet glass may be of a white or other colour. When it is required to form a pattern on the surface of the sheet of glass, cover the intended part with gum, and then sprinkle the required coloured pounded glass on it. The other portions of the pattern are likewise similarly prepared, and pounded glass of a different colour is sprinkled on those. These operations are repeated until the required number of colours are sprinkled on. The sheet of glass is then heated to the required degree to reduce the pounded glass to almost a liquid state; when the glass is removed from the furnace the pounded glass is found to have fixed itself into or on to the surface, and forms a rough face. If the sprinkled sheet of glass be left under heat for a longer time the pounded glass runs and intermixes itself in the surface, and thus produces a smoother face.

In carrying out the second of the above described methods of this process the inventor takes broken or shaped fragments of coloured or plain glass, or glazed ware or metal, and arranges them in any desired pattern, placing them in a metal mould. He then spreads over them a layer of pounded glass or other vitreous substance in such a manner that the powder shall enter the interstices between the fragments forming the pattern, and shall cover the entire back surface of the pattern to such a depth as may be convenient. He then removes the whole to a furnace and vitrifies the mass, thus cementing together with a thorough vitrified cement the coloured device and giving it a solid back.

STEAM ENGINE GOVERNOR.

BY MR. W. BELLIS.

FIG. 1.

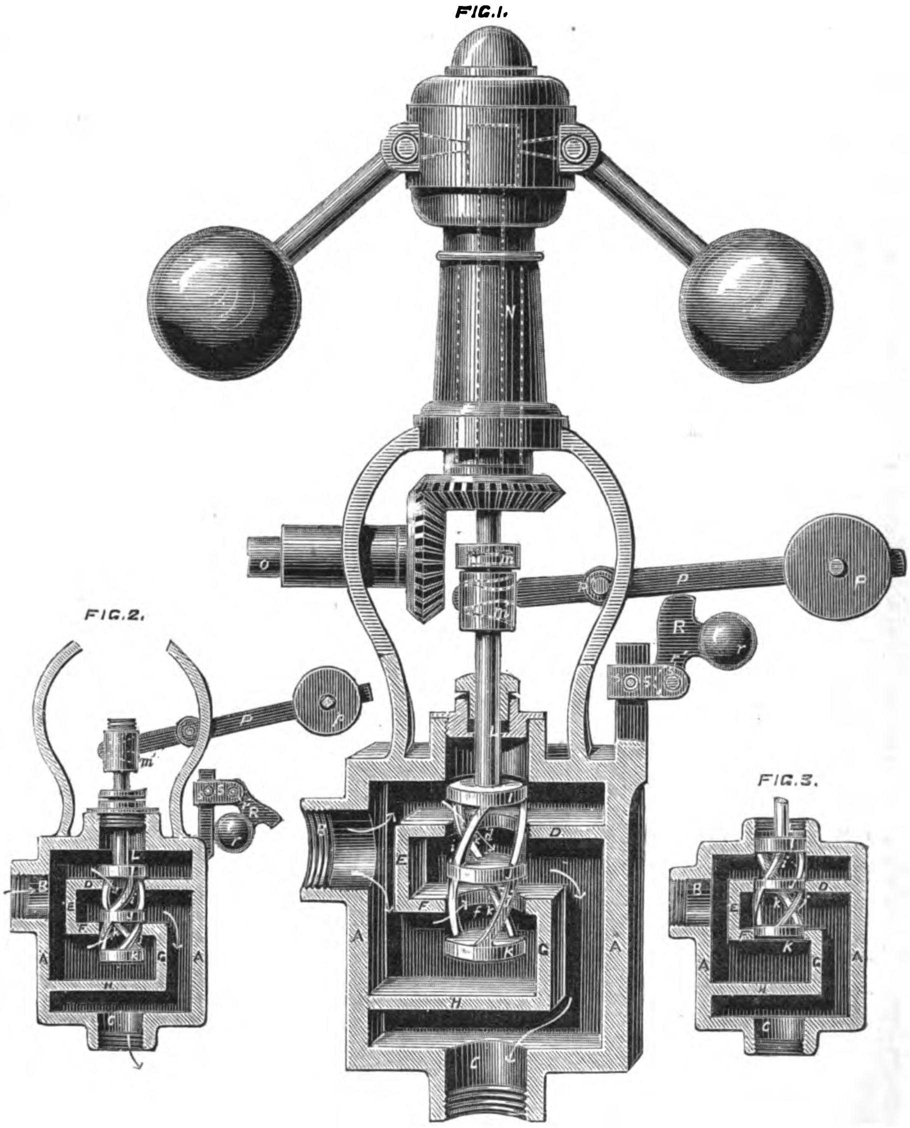

FIG. 2. FIG. 3.

The annexed engraving refers to an invention by William Bellis, of Richmond, U.S., and recently patented in England. The invention relates, firstly, to a peculiar form of governor valve, which, in addition to the advantages of great compactness and mobility, possesses the facility of closing automatically in the event of the snapping or running off of the governor belt, or the sudden suspension of the governor action from any other cause or accident. Secondly, to a device for holding such governor valve open when the steam inlet valve or throttle is shut, so as to enable the engine to be started by the opening of the said throttle.

In our engraving, fig. 1 is an axial section of a valve and its accessories embodying this invention, the governor being at rest, the valve open, and the steam just entering from the open throttle. Fig. 2 shows the same valve with the gravitating catch or tumbler released, the valve being under control of the governor. Fig. 3 shows the valve automatically closed in consequence of the running off of the belt or other accident to the governor. The valve chamber A is of a rectangular external form, and has the customary inlet neck B and outlet neck C, which are separated by an S-formed diaphragm D E F G H, of which the portions D F and H form horizontal shelves connected by the vertical walls E and G. Of these parts the shelves D and F are traversed by circular ports d and f of equal size. The governor valve proper consists of three precisely equal parallel and equidistant discs I J K, of which the upper and lower discs I and K are separated from the middle disc J the precise distance which separates the shelves D and F. The several discs are connected by ribs i j k, which are made flush with the peripheries of the discs and of a spiral form, in order that in the vertical oscillation of the valve it may be guided easily and truly with the opening of the seats, and that every part of the seats may be equally subjected to wear. L is the valve stem, which is connected to the governor stem M by a swivel m; N is an ordinary governor, of which O is the driving shaft.

The stem coupling m^1 is slotted, as shown, to receive the lever P, which is fitted with an adjustable weight p, and works on a centre at p^1. This weighted lever may be used to give a variety of speeds to the engine, or to adjust its velocity to a certain number of revolutions; but it is also used to sustain the valve I J K in the open position when the engine and governor are at rest. This is accomplished by the aid of a tumbler R, which is weighted at r and pivoted at r^1 to a sliding block S, which is adjustable by a set screw s. When the engine is to be started, the valve I J K is held open by the weighted stop R being turned up under the lever P. The stop R is held in position by the weight of the governor balls and weighted lever P. The steam being applied, the governor begins to operate, and as soon as it attains sufficient velocity the balls rise and release the stop R, the weight on which immediately causes it to drop out of the way, and leaves the governor and valve to operate in the usual manner.

It will be observed by reference to the construction and arrangement of the valves I J K and apertures d f, that the ports are closed both by the extreme extension and by the extreme contraction of the governor balls, so that the ports d f may be closed or partially so as may be required to check the engine in the regular legitimate action of the governor while in motion; or the ports may be suddenly and completely closed, and the engine stopped by the breaking or running off of the governor belt. With this arrangement it is always necessary either to prop the lever P in the manner described, or to elevate it by hand before starting the engine. When the governor valve is closed by the extreme extension of the balls, the discs I J close or fill the ports d f and prevent the passage of steam, and when it is closed by the extreme contraction of the balls, the discs J K occupy the ports d f and equally prevent the passage of steam.

In addition to the feature of closing in either direction, the provision of double ports and the peculiar construction of the triple valve I J K with an open centre admits of the employment of a valve of small diameter. Thus an ordinary governor valve of 2in. in diameter has an area of 3·1416 square inches. The area can be obtained by the use of 1½in. valve of the improved construction, the area of the two discs being 3·534, from which deduct ·375 for the bars or wings i j k, and an area of 3·159 is left for the passage of steam. A small valve has less friction, and as it requires less power to operate it than a larger one the governor is more sensitive and mobile. This valve further possesses the advantage of being completely steam balanced, whether open or shut, and under every pressure of steam.

The Suez Canal Company has issued a statement showing the position of the works on August 15. It appears that 5,103,159 cubic metres then remained to be extracted from the canal. During the month ending August 15 the extraction effected amounted to 1,548,206 cubic metres. With a slight acceleration of the extraction the canal will thus be completed by the middle of November.

ON THE MONCRIEFF SYSTEM OF WORKING ARTILLERY AS APPLIED TO COAST DEFENCE.

By Captain Moncrieff.

(Continued from page 261.)

THE next requirement in a coast battery, viz., to be able to follow an enemy amidst clouds of smoke, and to lay the guns on him with precision and despatch, formed a more embarrassing difficulty still. On the one hand, the ports must be constructed for muzzle-pivoters to give protection. On the other hand, if they are made so small it is difficult to see through them, to fire correctly and quickly at different elevations, and on different sides on a moving enemy. The battery is in the position of a knight who must either expose his vitals to his enemy's lance or put on armour that paralyzes his sword arm. There is as much protection in the power of being able to strike as there is in being able to guard. As naval actions are likely to be short and decisive, it must have appeared extremely doubtful whether it was worth purchasing increased safety at the expense of losing the attacking power.

The last of the three requirements in coast defence stated was the necessity of using the most powerful cannon. This did not present the same difficulty as the other two, because the designers of our defences had been presented by my friend Captain Coles with the means of mounting the heaviest guns to fire in any required direction. When very large and valuable guns are used, it is not advisable to cramp their action and restrict it to a small area. The turret was therefore preferred to the casemate when lateral range was required; and though apparently very expensive it was in reality cheaper than casemates, because, although the mounting of the guns in this manner cost more, they were enabled to do much more work, and there was thus an economy both of guns and men.

Having thus far endeavoured to describe the extraordinary difficulties which the new improvements in artillery inevitably entailed on the engineers, I shall now direct your attention for a short time to the difficulties in which the same improvements involved the artillerymen themselves. These difficulties, though not quite so important as the engineering ones, were very serious indeed, and have not yet been quite overcome. They consisted chiefly in the difficulty of making carriages and platforms strong enough for the new and powerful rifled guns. These pieces burnt enormous charges of powder, and hurled bolts as heavy as an old field-piece at 1,000ft. a second. The recoil of such guns represents a violence of force the like of which man has never had to deal with before. Imagine 12, 18, or 25 tons of compact iron started in an instant into rapid motion with a violence that mocks the blow of a steam hammer. This force has to be controlled and restrained. It is no wonder, then, that, when met directly and stopped by friction, as is now done in the ordinary system, the difficulties are enormous. The horizontal strain on the platforms, pivots, and racers is so great that it has not yet been quite successfully met; constant changes and inventions are being made to render this force more harmless.

I hope I have now conveyed to your minds some idea of the embarrassment and difficulties which have fallen upon both the artillery and engineers by the rapid improvement of these formidable engines of war; and of the persistent and able struggle which both have maintained to meet directly the terrible forces with which they have to contend. They have both succeeded to a wonderful extent, but their success is blighted by that curse of the science they practise, the law that up to this time has existed—viz., that what was gained in protection was lost in efficiency, and the converse. Happily I had the good fortune to conceive and develope an idea which abrogates this law. The very force the existence of which has been so great a difficulty in the artillery question has been compelled to perform a service that at once sweeps out of existence a great many of those other difficulties that embarrassed fortification. When two evils co-exist, it is sometimes good policy to make them destroy each other. I shall now refer shortly to the train of ideas that led me to think of solving the important problem in quite a different manner from that in which it had been attempted, which had led to the adoption of a most expensive class of works. My solution gives a system capable of mounting the heaviest artillery, while it simplifies the vexed question of fortification. It gives protection without the expense of using iron, and free lateral range to the guns without exposure.

The system is indeed a simple one; it does not require either brute strength or heavy expenditure for its application; nor does it need mighty forges to weld iron walls to protect our guns and gunners; it only calls to our aid the simplest and most docile forces of nature. Instead of trying to meet force by force, I make my guns bow to the inevitable conditions which science has imposed; and instead of wasting energy, money, and skill in attempts to raise a buttress against the new artillery, I employ the hitherto destructive force of recoil to lower the gun below the natural surface of the ground, where it can be loaded and worked in security and in comfort; and, at the same time, I have made that destructive force so much my servant that I compel it at my pleasure to raise the gun again into the fighting position whenever it is required. In 1855, while watching the interesting operations before Sevastopol, and endeavouring, as well as I could, to understand the conditions under which the siege-artillery was used, I conceived the idea which is now realised. It was then that I saw the value of earth and the importance of simple expedients. It was plain that the weak point of a battery was the embrasure, which formed a mark to fire at, an opening to admit the enemy's shot, and required constant repair even from the effects of its own gun, which in firing injured the revetments of the cheeks. I also came to the conclusion in my own mind that a remedy for some of these defects could be devised. Afterwards I worked at various plans, of which sketches were made or models; but each design had defects which discovered themselves to me as my experience increased.

The real difficulty of the thing arose from the necessity of providing for the enormous strain of the recoil. These early designs, which were sometimes excellent in other respects, broke down at this difficulty, and although some of them no doubt would answer with small guns, they were not calculated to meet the tremendous recoil of large rifled pieces. At last I hit on a simple principle that would meet this difficulty to advantage, the interposition of a moving fulcrum between the gun and platform. Then I knew that the problem could be solved; and feeling the great importance of the subject, I resolved to devote my efforts to working it out completely. While directing my attention to this simple and then apparently obscure matter, I was, as you may imagine, neither an idle nor disinterested watcher of the progress of artillery. Every step in advance was riveting the certainty in my mind that the system would one day be required, and with this conviction I refused to allow either discouragement or delay to make me desist. I shall now endeavour to explain shortly the system which bears my name, as far as it relates to coast defence. It consists of three parts:—1st. The mechanical principle of the gun carriages. 2nd. The form internal and external of the batteries. 3rd. The selection of ground for placing the batteries, and the arrangement for working them to the greatest effect; or, in other words, the tactics of defence for positions where the system is employed.

The principle on which the carriage is constructed is the first and most important part of the new system, because on it depends the possibility of applying the other parts. This principle may be shortly stated as that of utilising the force of the recoil in order to lower the whole gun below the level of the crest of the parapet so that it can be loaded out of sight and out of exposure while retaining enough of the force above referred to to bring the gun up again into the firing or fighting position. This principle belongs to all the carriages; but the forms of these carriages, as well as the method in which this principle is applied, vary in each case. For instance, in siege-guns, where weight is an element of importance, the recoil is not met by counterpoise. With heavy garrison guns, on the other hand, which when once mounted remain permanent in their positions, there is no objection to weight. In that case, therefore, the force of gravity is used to stop the recoil, because it is a force always the same, easily managed, and not likely to go wrong; and as these carriages are employed for the most powerful guns, it is a great advantage to have the most simple means of working them.

It has been already mentioned that the principal difficulty arose from the enormous and hitherto destructive force of the recoil of powerful guns; and here I shall point out the manner in which that difficulty is overcome. That part of the carriage which is called the elevator may be spoken of and treated as a lever; this lever has the gun-carriage axle at the end of the power-arm, and the centre of gravity of the counterweight at the end of the weight-arm, there being between them a moving fulcrum. When the gun is in the firing position the fulcrum on which this lever rests is almost coincident with the centre of gravity of the counter-weight, and, when the gun is fired, the elevators roll on the platform, and consequently the fulcrum, or point of support, travels away from the end of the weight-arm towards the end of the power-arm, or, in other words, it passes from the counter-weight towards the gun. Notice the important result of this arrangement. When the gun is fired, its axle passes backwards on the upper or flat part of a cycloid. It is free to recoil, and no strain is put upon any part of the structure, because the counter-weight commences its motion at a very low velocity. As the recoil goes on, however, the case changes completely, for the moving fulcrum travels towards the gun, making the weight-arm longer and longer every inch it travels. Thus the resistance to the recoil, least at first, goes on in an increasing progression as the gun descends, and, at the end of the recoil, it is seized by a self-acting pawl or clutch. The recoil takes place without any jar, without any sudden strain, and its force is retained under the control of the detachment to bring up the gun to the firing position at any moment they may choose to release it. The recoil, moreover, however violent at first, does not put injurious horizontal strain on the platform. In my experiments at Edinburgh with a 32-pounder, I found that so slight was the vibration on the platform caused by firing that the common rails on which the elevators rolled in that experiment, and which were only secured in the slightest manner, did not move from their position, nor even when heavy charges or double shot were used did sand and dust fall off their curved tops.

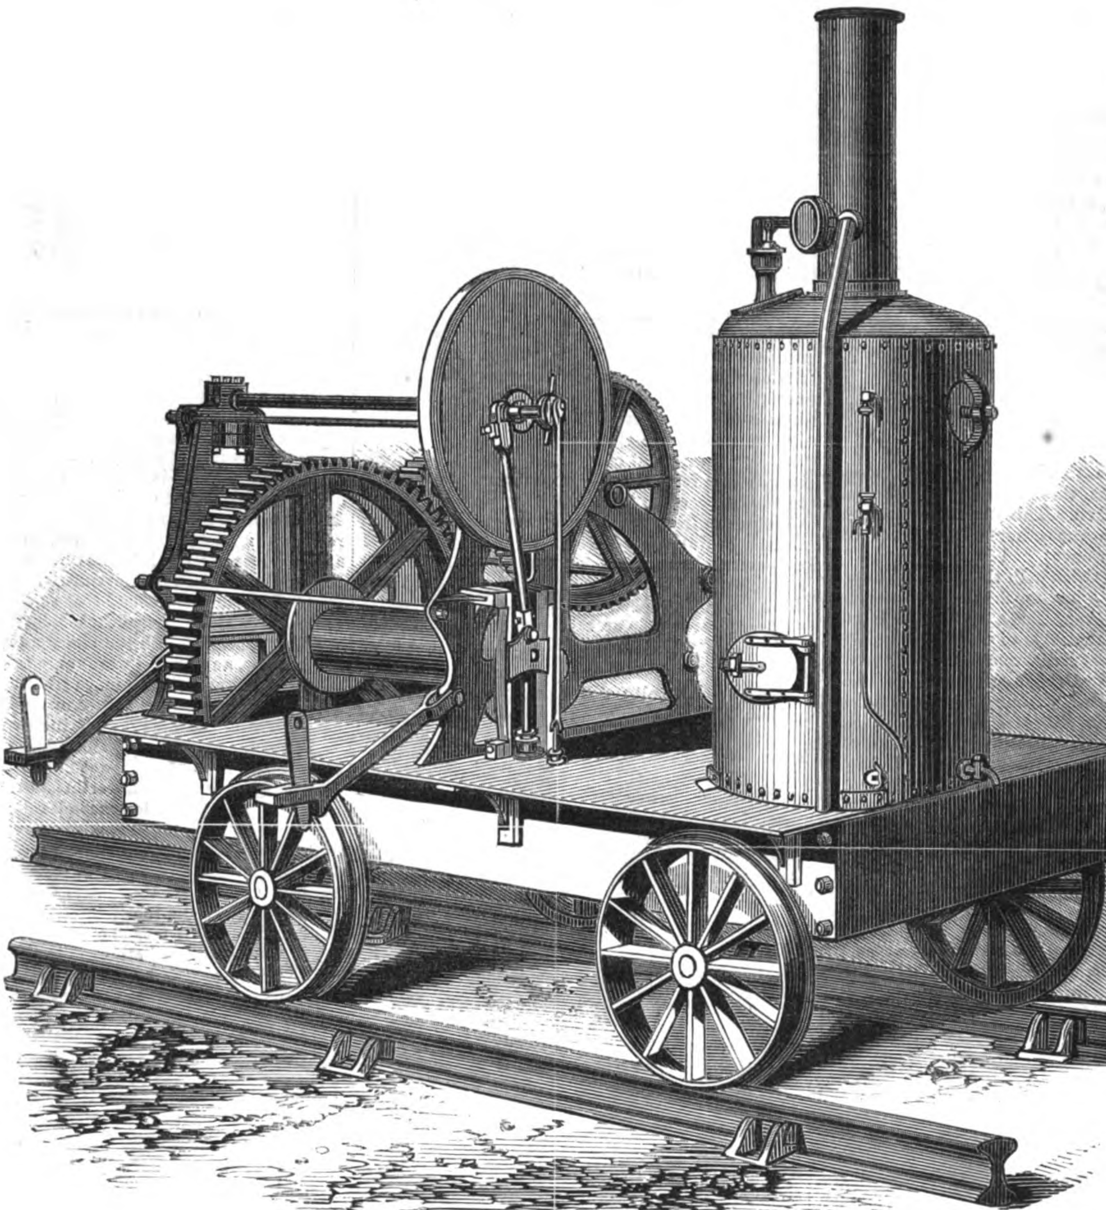
At a still earlier experiment made with a model of a 95cwt. gun, the model was fired on the ice with excessive charges, and nevertheless remained stationary. This valuable concomitant of the system cannot be appreciated fully without referring to the difficulties that have been experienced, and are now felt, in getting pivots, platforms, &c., on the ordinary system, strong enough to mount the new artillery, where the recoil is stopped by friction applied directly by means of what are technically called "compressors" attached to the platform. I shall not detain you by detailing these difficulties, but will only state that the first two 12-ton guns on ordinary carriages that were fired in casemates (which happened a few months ago) at Gilkicker Fort were both *hors de combat* the first shot. This alarming event showed that, with all the experience of ancient and modern artillery (and the carriages referred to were the legitimate exponents of the results of that experience), there was still room to doubt whether the problem of meeting recoil had been at that time completely solved by the existing system. The accident referred to was serious, because it might occur in action, and, in that event, would disable the gun *pro tempore* as completely as if it had been dismounted by a shot.

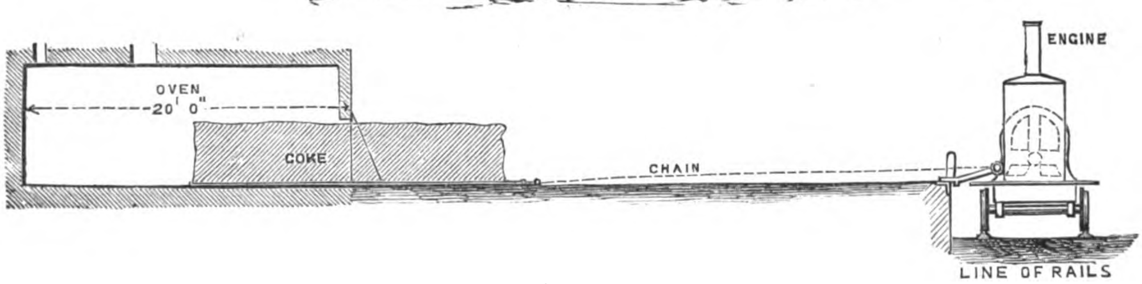
Some credit may be claimed for the new system on the ground that it provided a carriage for a heavy piece of artillery on an entirely new principle, in which not a single part was copied from anything that had been formerly used, dealing with new conditions and performing new functions that no other carriage had done, and yet this new carriage (the first complete one of its kind) has now fired two hundred rounds. This practice has been carried out with only a few accidents which pointed to defects in the gearing, which were easily remedied. By treating this violent force in the manner above described, a good deal of the strength that is required in other systems becomes unnecessary, and, at the same time, the recoil, however violent, can not only be met, but utilised. Together with the carriages there are some improvements of minor importance, such as trunnion pointers, reflecting sights, graduated racers, and so on, which it would be out of place to discuss at present, but which contribute to the efficiency and completeness of the system, and are more or less required for carrying it out as a consistent whole for coast defence.

THE word dun (to ask for a debt) owes its origin to a famous English bailiff, named John Dunn, in the time of King Henry VIII., who plied his hard trade of collecting doubtful debts with remarkable success. When every other resort had failed, creditors would threaten to put Dunn on their debtors, and hence the phrase of dunning which is so common now-a-days.

COKE-DRAWING MACHINE.

BY THE NORTH STAFFORDSHIRE ENGINEERING COMPANY.





COKE-DRAWING MACHINE.

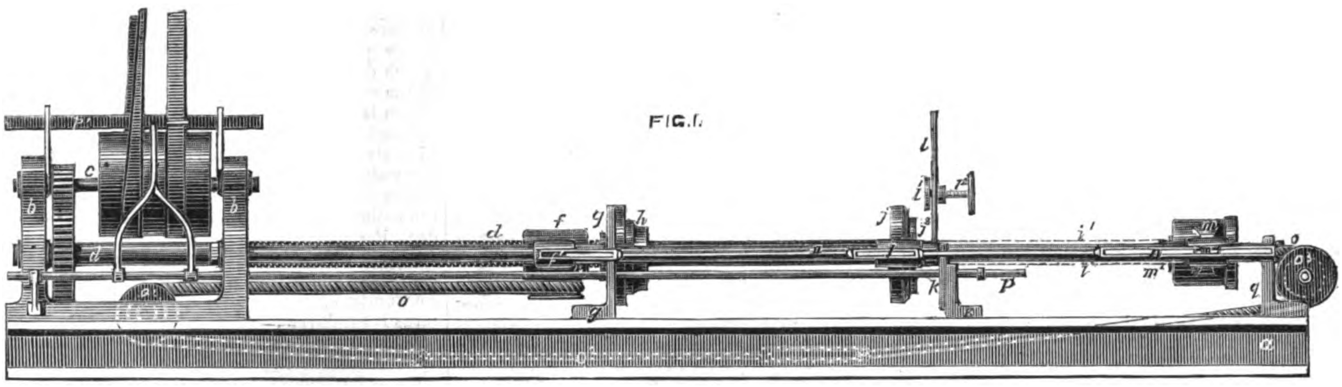
THE severe work of coke drawing by manual labour has been superseded by the machine illustrated in the accompanying engraving. The apparatus has been manufactured and erected by the North Staffordshire Engineering Company, of Stoke-upon-Trent, for the firm of Messrs. Stanièr and Company, of Newcastle-under-Lyne, and has now been at work for several months at their iron works. We are assured that these machines could not give more satisfaction to those engaged in drawing coke ovens on account of the facility with which they are handled by the workmen, and also in an economical point of view. The machine draws from 100 ovens, each oven being 20ft. 7in. by 7ft. 6in., and arranged in two rows of fifty each, back to back. The average weight of coke to be drawn from each oven is about 4 tons, which load is drawn in the short space of three minutes. A line of rails is laid down opposite each row of ovens, along which road the machine travels, propelling itself by gearing from the fixed engine. The thrust from the crab, when the oven is being drawn, is taken by the hinged struts. These struts when in position rest on an iron curb, which is fixed on the wall of the sunken roadway. The cylinders are 6½in. diameter, with a stroke of 12in. The total weight of coke drawn by this machine is upwards of 725 tons within six working days, and the cost of that amount of work, including labour, coal, &c., does not exceed one halfpenny per ton.

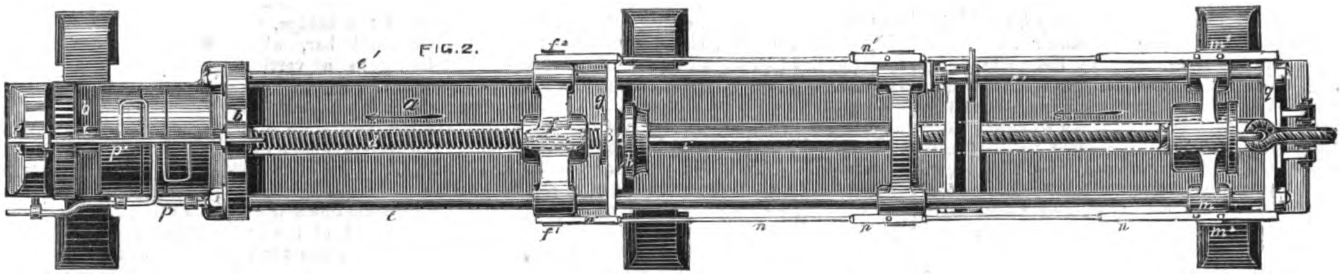
STEAM FIRE ENGINE FOR THE MIDLAND RAILWAY COMPANY.

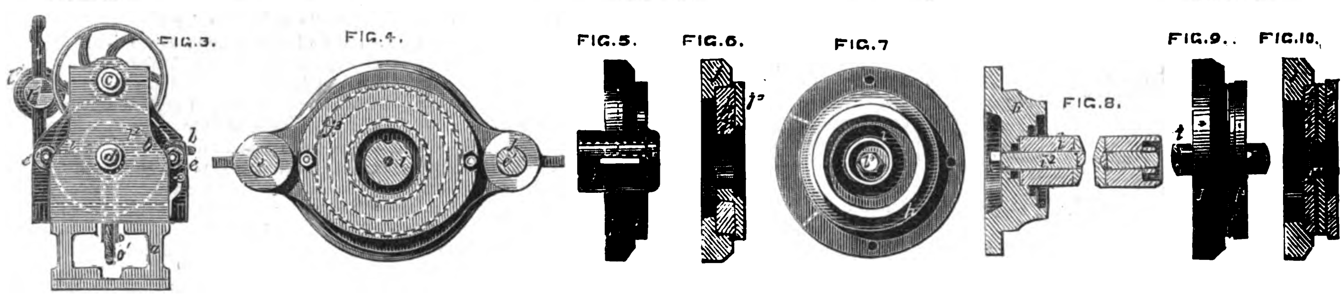
A NEW and powerful long stroke double-cylinder steam fire engine has recently been supplied to the Midland Railway Company's Locomotive Works at Derby by Messrs. Merryweather and Sons, of London. This engine is of the same size and construction as the engine with which these makers so successfully competed at Elswick Works, Newcastle-on-Tyne, in July, 1868, before a jury of eminent engineers, who afterwards selected the engine then tried as the best for the Corporation of Newcastle-on-Tyne. The new engine has two horizontal steam cylinders, each 6¾ft. diameter, and two direct and double-acting pumps, each 5¼ft. diameter, with 18in. stroke of pistons. On delivery at Derby, it was submitted to the usual tests and kept working for some hours, and was much admired for the easy manner in which it maintained steam whilst working at full pressure, and the ease with which it was managed. It delivers over 500 gallons per minute, and projects a stream to 180ft. high or several streams at one time. We hear that Messrs. Merryweather and Sons sent off four such engines, but with single cylinders, a short time since to the Madras Railway Company, and they are now completing two more for the Oude and Rohilcund Railway Company. Such powerful engines as these will prove of immense service should fires occur on the works of the companies who have provided themselves with them.

MACHINE FOR MANUFACTURING SHEET METAL ROLLERS

BY MR. THOMAS REEDER.







MACHINERY FOR MANUFACTURING SHEET METAL ROLLERS.

THE invention illustrated in the accompanying engraving has been patented by Mr. Thomas Reeder, of the Green Bank Brass and Tin Plate Works, Preston. It is in satisfactory operation at Mr. Reeder's works, and is particularly beneficial when used for making rollers of tinned sheet iron, but it may be used in making other sheet-metal rollers, the object being to produce rollers that are perfectly cylindrical from end to end. In practice, the edges of a plate of sheet metal are first bent over, and then the sheet is formed into a tube or cylinder with the bent edges locking into each other as usual. This tube is then put on a mandril having a longitudinal groove for the joint. A die of the exact diameter of the finished roller is then drawn over the tube on the mandril, and the action of this die equalises the irregularities in the thickness of the sheet metal, thereby producing a roller of uniform diameter throughout its length.

Fig. 1 in our engraving is a side elevation of Mr. Reeder's machine; fig. 2 is a plan, and fig. 3 is an end view of the same; figs. 4, 5, and 6 are detached views of the die and die holder; and figs. 7 and 8 are detached views of the mandril and the chuck, which supports the same on an enlarged scale. *a* is the bed of the machine; *b*, the headstock carrying the driving apparatus; *c* is the driving shaft, on which is a pinion gearing into a wheel on the screw shaft *d*. This shaft is supported in bearings on the headstock *b*; *e* e^1 are two stationary guide bars bolted to the frame *b* at one end, and to a frame *g* at the extremity of the bed *a*; *f* is a screw nut made to traverse by the screw *d*; this nut slides on the guide rods *e* e^1. A frame or rest *g* is bolted to the bed *a* for the purpose of supporting the end of the screw *d*, and also to hold the chuck or block *h* to which the mandril *i* is bolted, as shown detached in figs. 7 and 8. The die is also a support to the mandril. *j* is a crosshead sliding on the guide rods *e* e^1; to this crosshead *j* is attached the die j^1 and die plate j^2 (see figs. 4, 5, and 6); *k* is a stationary frame through which the guide rods *e* e^1 pass; *l* is a lever hinged to the rod e^1 and in contact with the frame *k*—its use will be presently described; *m* is a crosshead sliding on the guide rods *e e* connected by the rods *n* n^1 to the screw nut *f* and crosshead *j*. A rope *o* secured to the under side of the screw nut *f* passes over the grooved pulley o^1 and is coupled below to an adjustable screw rod o^2; from the nut at the other end of this rod, the rope *o* is taken over the grooved pulley o^3 and fastened to the back part of the crosshead *m*.

In making sheet metal rollers the operation is as follows:—A sheet of metal is cut of the length and width required to make the roller, the edges are then bent, and an unfinished tube is made by locking the bent edges into one another as usual. The engraving represents the machine in position ready to receive the unfinished tube. In figs. 1 and 2 the tube is shown in dotted lines, marked i^1. The attendant rests one end of the tube on the end of the mandril *i*, which is made taper at the extremity, the joint of the tube being placed over the longitudinal groove in the mandril *i*. The machine is then set in motion by moving the rod *p* connected to the starting rod p^1 so as to bring one of the driving straps on the driving pulley. By this means the screw is caused to revolve, and, as the screw nut *f* traverses it, draws with it by the rods *n* n^1 the crosshead *j* carrying the die j^1, and also the crosshead *m* in the direction of the arrow. At the front of the crosshead *m* is a small projection m^1 which enters the tube i^1, and, by the motion of the various parts of the machine, the tube is forced on to the mandril *i*, the crosshead *j* and die j^1 moving over the mandril slightly in advance of the tube i^1. After the tube i^1 is forced on the mandril, the direction of the screw *d* is reversed, and the die j^1 is forced over the tube, which remains stationary on the mandril. In case the die should have a tendency to push the tube i^1 off the mandril instead of passing over it, the operator makes use of the lever *l* and plate l^1 which is secured to a screw working in the lever *l*. The lever *l*, being hinged to the guide rod e^1, is brought into a horizontal position, resting on the guide rod *e*; the plate l^1 is then opposite the end of the mandril, and it is brought up against the end of the tube by means of the screw and hand wheel l^2; the stationary frame *k* maintains the lever *l* in position. The lever *l* is shown by dotted lines in fig. 3 in the position it occupies when brought against the tube i^1.

When the die j^1 has passed over the entire length of the tube i^1, the latter is ready to be soldered, which is done while the machine is at rest; after soldering, the machine is again started so as to move the die in the direction of the arrow in fig. 2, the die j^1 removing all surplus solder and finishing the tube so that it is perfectly cylindrical and ready to be taken off the mandril. To accomplish this there is a ring of metal in two pieces, which ring fits the mandril *i* accurately, and is held in position in front of the die j^1 by the strap or plate j^3. On reversing the motion of the machine, this ring is pushed over the mandril, coming in contact with the end of the tube l^1, and forcing it off the mandril *i*. It will be seen, by referring to figs. 1 and 2, that the connecting rods *n* n^1 are at liberty to slide over the lugs or projections f^1 f^2 on the screw nut *f*; the connections of the rods *n* n^1 to the crossheads *j* and *m* are rigid by the pins, as shown. When forcing the tube off the mandril, in some cases, the tube is so firm that it might be injured by the continued action of the pushing-off apparatus; to obviate this the connecting rods *n* n^1 are at liberty to slide on the projections f^1 f^2.

While the machine is at work pushing off the tube, or, at other times, when forcing the die over the tube, the motion is conveyed direct from the screw nut *f* by means of the rope *o* and screw rod o^2 to the crosshead *m*, which, by the action of the connecting rods *n* n^1, only draws the crosshead *j* over the mandril; but, should the resistance be greater than the rope readily overcomes, then the rope *o* yields, which allows the connecting rods *n* n^1 to slip over the projections f^1 f^2, and thus slightly ease the pressure of the crosshead *j* and die j^1. The tubes may be soldered, but, in some cases especially when sheet iron is employed, Mr. Reeder dispenses with solder and draws the dies over the tube; he then removes it off the mandril and rivets the joint. It may be found advisable sometimes to put a clamp over the tube on the projection m^1 of the crosshead *m* to facilitate the drawing of the tube off the mandril. The rod *p* is provided with two set washers, by which the machine is stopped at either end of the stroke. The length of each stroke depends on the tube to be made. The stroke can be altered by altering the position of the projections m^2 m^2 in the slot

of the connecting rods n n^1, and securing them as shown; the length of the rope must be altered to correspond, and this is done by means of the screw rod and nut o^2.

Figs. 4, 5, and 6 represent an elevation, edge view, and plan of the die and its frame. e e^1 are the guide rods; j, the crosshead; j^2, a flat plate fitted by grinding into the crosshead j; j^1 is the die ground to fit into the plate j^2; j^3 is a plate or strap bolted to the crosshead j securing the die j^1 and plate j^2 to the crosshead j; and i is the mandril, seen best in figs. 4 and 8. Figs. 7 and 8 represent the chuck or block h and the mode of securing the mandril i to it. This chuck h is bolted to the stationary frame g; in its interior it is formed into annular recesses, into one of which the mandril i fits and is secured by means of a long bolt i^2, which passes through the block h and mandril i, and is drawn tight by a nut in a countersunk recess at the other end of the mandril i.

Figs. 9 and 10 represent a spring die made of a piece of hardened round steel wire r long enough to go once round the tube, bearing against a piece of india-rubber fitting into the plate j^2, into which the die r is held by the circular disc r^1, the whole being held in the crosshead j by the plate j^3 as already described. This spring die is used in cases where the thickness of the metal under operation is very unequal. The solid die can be employed to follow the spring die on the same tube. Tubes made by this improved machinery are adapted for all purposes in which sheet metal tubes or rollers have been previously employed, and particularly where great precision and exactitude are necessary, as in beams for looms, rollers for warping machines, drums of spinning machines, and other purposes.

THE HYDRAULIC SWING BRIDGE OVER THE OUSE.*

By Sir William Armstrong.

The formation of the Hull and Doncaster section of the North-Eastern Railway necessitated the crossing of the River Ouse by an opening bridge, so as to admit the passage of the important traffic carried on in large sailing vessels. It was also necessary that there should be not more than one pier in the navigable channel, with a clear opening of not less than 100ft. on each side. The requisites of the railway and river traffic necessitated a construction that admitted of being opened and closed very rapidly. It was also necessary that the power applied should be capable of controlling with great accuracy the momentum of so ponderous a mass, and hydraulic power was therefore selected as the agent. The instances in which hydraulic power had been previously applied to the opening and closing of movable bridges are very numerous. Most of these bridges have been erected for the passage of railway traffic, and they may be divided into three classes. First, swing bridges on which the bridge is lifted from its solid bearings by a central press previously to being turned; second, swing bridges on which the bridge rests upon a circle of two rollers; third, drawbridges on which the movable platform is drawn back and pushed forward in the line of the roadway.

In addition to the hydraulic bridges comprised in these three classes, there is one example of a bridge on the bascule plan being worked by hydraulic power. This is at Liverpool, over one of the dock entrances. The first hydraulic swing bridge was erected in 1852 over the River Severn, on the Gloucester and Dean Forest Railway, and the first hydraulic drawbridge was erected in 1853, over the River Tovey, on the South Wales Railway, near Carmarthen. All the swing bridges which turn on a centre pier, and span an opening on each side, have been made to turn on live rollers without being lifted; because in bridges of that construction neither extremity can have any steadying support in the act of turning, but in some instances a central press has been applied to relieve the rollers of part of the weight. Where single-leaf swing bridges are lifted by a central press, the deflection is taken off by letting down the bridge upon its solid bearings when closed; but in the case of drawbridges and swing bridges not lifted by a central press, hydraulic machinery is applied to lift the over-hanging end or ends so as to take off the deflection after closing. The openings crossed by these various forms of bridges have varied from 30ft. to 100ft. span.

The heaviest bridge to which the central lifting arrangement has been applied is one over the Regent's Canal, near the London Docks, in which instance the weight lifted and turned amounts to 450 tons. In bridges with the central press, the head of the lifting ram fits into an inverted cup upon the bridge to allow of oscillating movement, and the bridge in swinging turns upon the water by carrying the ram round with it. The pressure of water employed in the central hydraulic press is about 800lb. per square inch; and in the largest of these bridges the diameter of the ram turning upon the water is 51in. In most cases the bridges are in connection with a system of hydraulic pressure applied to cranes and other machines in the vicinity, the pressure being supplied in the usual manner by steam engines pumping into accumulators. But in some few instances, where there is not such a supply of power at hand, the pressure is supplied by hand pumps charging the accumulator, and thus storing up the power ready for application whenever required. At the Ouse Bridge there was no supply of hydraulic power at hand, and in that instance the total power required was too large to be supplied by hand labour. It was further necessary, on account of the position of the swing bridge, either to convey the power to the centre pier by a pipe under the bed of the river, or to produce it upon the pier by placing a steam engine within the pier itself, and the latter plan was adopted.

The total length of the bridge, fixed and movable, is 830ft. The fixed portions consist of five spans of 116ft. from centre to centre of piers. The bridge being for a double line of railway, each span is composed of three wrought-iron girders of the bowstring form, the centre girder having a larger section to adapt it for its greater load. These girders have single webs, and are 9ft. deep in the centre. The total width of the bridge, from outside to outside, is 31ft. Each of the piers for the fixed spans consists of three cast-iron cylinders, of 7ft. in diameter, and about 90ft. in length. The depth from the under side of the bridge to the bed of the channel in the deepest part is about 61ft. The headway beneath the bridge is 14ft. 6in. from high water datum, and 30ft. 6in. from low water. The swinging portion of the bridge consists of three main wrought-iron girders, 250ft. in length, and 16ft. 6in. deep at the centre, diminishing to 4ft. deep at the ends. The centre girder is of larger sectional area than the side girders, and, instead of being a single web, is a box girder 2ft. 6in. in width, with web plates 7-16in. to 5-16in. in thickness and the top and bottom booms contain about 132 square inches of section. The roadway is carried upon transverse wrought-iron girders, resting upon the bottom flanges of the main girders. In the centre of the bridge the main girders are stayed by three transverse wrought-iron frames, securely fixing them together; and over the top of these frames a floor is laid, from which the bridge-man controls the movements of the bridge. An annular box girder, 32ft. mean diameter, is situated below the centre of the bridge, and forms the cap of the centre pier; this girder is 3ft. 2in. in depth, 3ft. in width, and rests upon the top of six cast-iron columns, each 7ft. diameter, which are arranged in a circle, and form the centre pier of the bridge. Each of these columns has a total length of 90ft., being sunk about 29ft. in the bed of the river. A centre column, 7ft. diameter, is securely braced to the other columns by a set of cast-iron stays, which support the floor of the engine-room. This centre column contains the accumulator, and forms the centre pivot for the rotation of the bridge. The weight of the swing bridge is 670 tons.

There is no central lifting press, and the entire weight rests upon a circle of conical live rollers. These are twenty-six in number—3ft. diameter and 14in. width of tread—and are made of cast iron, hooped with steel, and they run between two circular roller paths, 32ft. diameter. These roller paths are 15in., and are made of cast iron, faced with steel; the axles of the rollers are horizontal, and the two roller paths are turned to the same bevel. The turning motion is communicated to the bridge by means of a circular cast-iron rack, 12½in. wide on the face, and 6¼in. pitch. It is shrouded to the pitch line, and is bolted to the outer circumference of the upper roller path. It gears with a vertical bevel wheel, which is carried by a steel centre pin, supported on the lower roller path. This is driven by a pinion connected by intermediate gearing with the hydraulic engine. There are two of these engines, duplicates of one another, either of which is sufficient for turning the bridge. The force required to turn the bridge is equal to about ten tons applied at the radius of the roller path. Each hydraulic engine is a three-cylinder oscillating engine, with simple rams of 4½in. diameter and 18in. stroke. These engines work at forty revolutions per minute, with a pressure of water of 700lb. per inch, and are estimated at 40-horse power each. The steam engines for supplying the water-pressure are also in duplicate, and are double cylinder engines, drawing three-throw pumps 2·8in. diameter, and 5in. stroke, which deliver into the accumulator. The diameter of the steam cylinder is 8in., and the stroke of the piston is 10in., each engine being 12-horse power.

The accumulator consists of 16½in. ram, with a 17ft. stroke, and is loaded with a weight of 67 tons, the weight being composed of cast-iron segments suspended from a crosshead and working down in the cylindrical casing formed by the centre cylinder. For the purpose of obtaining a perfectly solid roadway when the bridge is in position for the passage of trains, and also for securing the perfect continuity of the line of rails, the following apparatus is employed:—Each extremity of the bridge is lifted by a horizontal hydraulic press, acting upon levers forming a toggle joint, the piers having rams acting in opposite directions upon two toggle joint levers, which act one upon each side of the end of the bridge, and they are connected by a horizontal bar, which is confined by a stud sliding in a vertical guide, so as to ensure parallel action of the two toggle joint levers, and producing exactly parallel lifting of the two sides of the bridge. Three resting blocks, one under each girder, are pushed home when the end of the bridge is lifted, by means of two separate hydraulic cylinders, and the bridge is then let down upon the resting blocks by the withdrawal of the toggle joint levers, and the bridge ends are then perfectly safe for trains to pass over.

The hydraulic cylinders for this fixing gear at the two ends of the bridge are worked by the bridge-man from the centre platform by means of two levers, and for the purpose of enabling him to regulate the stopping of the motion of the bridge at the right place an indicator is provided, consisting of a dial upon a pedestal. This dial has two pointers, which are actuated by the motion of the bridge. One of these pointers makes two revolutions, and the other forty-two revolutions for one complete rotation of the bridge. These pointers are similar to the hour and minute hands of a watch, the slower pointer being analogous to the hour hand, and the quicker one to the minute hand. The bridge has no stop to its movement, and would swing clear past its right position if the turning power were continued, but the bridge-man, being guided by the indicator, knows when to stop and reverse the hydraulic engines, for the purpose of stopping the bridge in its right place When this is done, a strong bolt, 3in. thick, in each end of the bridge, pressed outwards by a spiral spring, is shot into a corresponding notch in the fixed girder work, so as to lock the bridge; and when the bridge is required to be opened these bolts are withdrawn by a wire cord leading to the platform on which the bridge-man is stationed.

As the accumulator is stationary, and the fixing gear at the ends of the bridge travels with the bridge, the communication of water power is made by a copper pipe passing up in the axis of the bridge, through the middle of the centre girder, having a swivel joint at the lower end. Also, as the hand gear for the bridge-man rotates with the bridge, while the hydraulic turning engines are stationary, the communication for working the valves is made by a copper rod passing down through the centre of the above pressure pipe in the axis of the bridge. This rod is connected by levers direct with the regulating valves of the hydraulic engines, and the engines are reversed in either direction by the action of a small hydraulic cylinder, which is governed by the movement of a three-port valve, actuated by this rod from the bridge-man's platform. The cylinders for working the fixing gear at the ends of the bridge are worked by valves placed upon the centre platform, in reach of the bridge-man, the pipes between the valves and the cylinders passing along the side of the roadway of the bridge. The time required for opening or closing of the bridge, including the locking of the links, is only half a minute, the average speed of motion at the extremities of the bridge being 6½ft. per second. For the purpose of ensuring safety in the working of the railway line over the bridge, a system of self-acting signals is arranged, that is actuated by the fixing gear at the two ends of the bridge, and a signal of "all right" is shown by a single semaphore and lamp on the fixed part at each end, but this cannot be shown until each one of the resting blocks and bolts is secured in its proper places.

* Institution of Mechanical Engineers.

THE HULL BOILER EXPLOSION.

WE annex a copy of Mr. Lavington E. Fletcher's report to the coroner on the steam boiler explosion that occurred at Hull on Thursday, September 16, 1869. It is dated Manchester, October 6, 1869, and runs as follows:—Sir,—In accordance with your communication, dated September 18, and addressed to Sir William Fairbairn, requesting him to come over to Hull, and investigate the cause of the explosion that occurred at Messrs. Hodges' Seed Crushing Mill, Holderness-road, on Thursday, the 16th ult., or, in the event of his not being able to do so, to appoint some one else to undertake the duty—in accordance with these instructions, I beg to inform you that I have examined the exploded boiler, as Sir William Fairbairn's state of health at the present time, I regret to say, quite prevents his leaving Manchester.

I visited the scene of the catastrophe on Wednesday, the 22nd ult., when I found that the exploded boiler was what is termed a "breeches" boiler. In this class of boiler, the two furnace tubes in which the fires are placed run into a single flue at a short distance behind the fire-bridge, being united by a combustion chamber, which tapers down from the width of the two furnaces to that of the single flue tube, and it is on account of this peculiar shape, the two tubes running into one, that the term "breeches" boiler has been adopted. On measuring the boiler I found that it was as nearly as may be 30ft. long and 7ft. in diameter, while the furnace tubes were 7ft. long by 3ft. in diameter, the combustion chamber 5ft. long by 3ft. 6in high, and the flue tube 18ft. long by 3ft. 6in. in diameter, the general thickness of the plates being from ⅜in. to 7-16in., with the exception of the one at which the primary rent occurred, which was barely ⅜in. The boiler had but one safety-valve, which was enclosed in a box, and fitted with a lever. At the end of this lever there were two weights, one of which amounted to 26lb. and the other 30lb., while there was also a dead weight of 70lb. within the box, bearing directly on the valve, so that, as the lever had a proportion of 6 to 1, and as the diameter of the valve was 3⅜in., the pressure of steam at which the valve would begin to blow, provided it were in good working order, would be as nearly as may be 45lb. per square inch, though it would rise if the steam were allowed to blow off strongly.

The boiler gave way in the flue tube, behind the furnaces and combustion chamber, the tube collapsing at the crown for a length of from 6ft. to 8ft. at about the middle of its length, and crumpling up as if made only of cardboard. The large opening formed by this rapture allowed the steam and hot water to rush out at each end of the boiler in a torrent, and it was this that caused the disastrous consequences already fully known to the jury. It was from this rush of steam and hot water that the furnace mountings were swept away, the fire-bars scattered like grapeshot over the garden beyond the boiler-house, and some of the fragments thrown to as great a distance as 140 yards, while it was also from this cause that the poor fireman was blown over the adjoining buildings and dashed against the roof of the coach-house.

With regard to the cause of the explosion.—The "breeches" type of boiler is an antiquated one, and has long since been discarded. Its use has been attended with a series of most disastrous explosions, and with the very rarest exceptions it is now never adopted. It is important to call general attention to this fact, so that those steam users who still have boilers of this class in use should at once have them thoroughly examined, to see whether they are safe for the pressure at which they are worked. Added to the peculiarities of the "breeches" type, the flue tube, though of so large a diameter as 3ft. 6in., was not strengthened as it should have been with encircling rings, flanged joints, or any other means; while it was not plated circumferentially as is the ordinary custom, but longitudinally, which does not give so much strength. Also the flat ends were stayed with diagonal rods, depending on a pin at each end, measuring 1¼in. in diameter; while the manhole was not guarded by any mouth-piece. In addition to this, there was no duplicate safety-valve, while the one provided was of very inferior and unreliable construction, so that it may be stated, without going into further particulars, that the boiler was decidedly second-rate in its construction as well as in its fittings, and that it was not adapted for high-pressure work.

While, however, the catastrophe might be attributed generally, and at the same time correctly, to the second-rate construction and equipment of the boiler, it may be pointed out that now that the explosion has occurred, and now that the flue tube has been crumpled up, and the fittings have been unseated, it is not easy to determine with certainty the final and exciting cause of the boiler's giving way, but, nevertheless, it may be desirable in conducting the present inquiry to go somewhat further into detail in this matter.

As already stated, the boiler failed from the collapse of the flue tube, and this, it is clear, could only have arisen from weakness of the tube, or excessive pressure of steam, or from the two combined. Sir William Fairbairn, some years since, instituted a series of experiments upon the power of flue tubes to resist external pressure without collapsing, and he found that the length of a flue tube is a most important element in its strength. Taking advantage of the result of his investigations, it appears that the flue tube under consideration, which was 18ft. in length, 3ft. 6in. in diameter, and may be taken as ⅜in. in thickness, should not have collapsed at a pressure of 45lb., at which the safety-valve appears to have been loaded. This is on the assumption, however, that the tube was circular, or very nearly so, and that the plates were well put together. To ascertain whether this tube had been truly circular or not, I measured its diameter vertically and horizontally at each end, and I found that there was only a variation of about ¼in. It does not follow, however, that the flue was circular throughout, and though true at the two ends it might have been out of shape at the middle, which is frequently found to be the case, while it was midway in its length that the crown failed. Added to this it must be remembered, as already stated, that the plates were not laid circumferentially but longitudinally, and it was close to the edge of the overlap of one of these longitudinal seams which ran along on the crown of the flue tube for a length of 6ft. that the primary rent occurred, when the top of the tube was driven down with so much violence as to cut its way completely through the bottom for a length of some 5ft. or 6ft. The character of the rupture is altogether peculiar, and very different to that which is found to take place in flue tubes plated circumferentially, and it certainly appears not to be by any means in favour of this mode of plating, though it is difficult to estimate the precise loss of strength.

There are other sources of weakness to flue tubes than that of original construction. The plates may become overheated, and thus weakened so as to be bulged down out of shape by the ordinary pressure of steam. The general appearance of this collapse, however, is by no means that of one which arose from overheating, whether from shortness of water or from any other cause, added to which, the top of the combustion chamber, which is as high as the top of the flue tube, is covered with scale, and so is the flue tube, with the exception of those parts where it has been cracked off by the bending of the plates consequent on the collapse, while, though the crowns of the furnaces are 3in. lower than that of the flue tube, it may be mentioned that they were perfectly sound throughout. It is possible, however, that the boiler may have been allowed to run short of water on some prior occasion when the crown of the flue tube, though not then rent, may have been so weakened that it was only a matter of time when it would give way. Thus the flue tube may have been flattened by construction, by wear and tear, or by overheating through shortness of water on some prior occasion, but the collapse has rendered it impossible to say positively whether such was the case or not. With regard to the question of excessive pressure of steam, the boiler, as it has already been pointed out, had only one safety-valve, and that of a very unreliable character. It had evidently never been constructed for the service it had to perform. In the first place, the lever was loaded with two weights, while a third was sometimes added, which is clearly an irregular mode of procedure. In addition to this, there was introduced within the valve-box, and immediately on the valve, a weight of 70lb., while there was a space of only three-quarters or seven-eighths of an inch between the top of this weight and the cover, and the arrangement of the whole was such that nothing was easier than for the valve to be jambed fast, so that it was clearly one that should not have been used, more especially seeing that it was the only one fixed to the boiler. As, however, this valve had been removed from the boiler before I made my examination, I have no means of saying whether it was stuck fast or whether it was free at the moment of explosion. Possibly this may be determined in evidence.

While, however, there is some difficulty in determining precisely whether this explosion was due to excessive pressure of steam or to the weakness of the flue tube, there is no difficulty in determining how it might have been prevented, which is the most important issue of such an inquiry as the one now in hand, as this may lead to the prevention of similar catastrophes in the future. The experiments already referred to on the strength of the furnace and flue tubes by Sir William Fairbairn, led to his strongly advocating that all such tubes should be strengthened with encircling hoops, while there is also a system of flanging the plates at the ring seams of rivets in these tubes, which has the same object in view. Both these modes of construction have for years past been very widely introduced, and are, consequently, well known. They have been found to be entirely successful, and are adopted in all modern first-class boilers. Had either one of them been employed in the present instance, the tube would have been amply secured against the danger of collapse. To have prevented the occurrence of excessive pressure of steam, the boiler should have been fitted with two efficient safety-valves, and it is a practice adopted by many of the members of the Manchester Steam Users' Association, and one that cannot be too generally adopted, to have one of thes valves of external dead weight pendulous construction, which it is extremely difficult to overload or tamper with, and to have the other adapted for blowing off, either for high steam or low water, so that in case the water should at any time fall below the desired level, the valve would be raised and the pressure of steam allowed to escape, and thus the source of danger removed, and explosion rendered impossible. Hundreds and hundreds of safety-valves of the two descriptions just named are working satisfactorily, and they cannot be too generally adopted. Were they universally applied, many explosions would be prevented.

In conclusion, although there may be a difference of opinion as to whether this explosion resulted from weakness of the flue tube or from overheating of the plates through shortness of water, or whether from excessive pressure of steam, there can be no question whatever that had the flue tube been strengthened with flanged seams, encircling hoops, or any other equally efficient means, and had the boiler been fitted with two reliable safety-valves, one of them arranged for relieving the pressure of the steam as soon as the water fell below the proper level, that this catastrophe would not have happened, that the fireman would not have been killed, and that this inquiry would not have been necessary.—I remain, Sir, yours faithfully,

LAVINGTON E. FLETCHER,
Chief Engineer to the Steam Users' Association.

RAILWAY FARES.

IT is a difficult task to arrive at the equalisation of the coins of the different nations of Europe, but it will be much more difficult to equalise the fares of all the railways already existing or in course of construction, so that on leaving home, the traveller may be enabled, if he knows the distance to be traversed, exactly to calculate the sum which he has to spend in order to arrive at his destination. There is such a difference in the price of construction, of management, of fuel, as well as in the physical condition of divers countries, that for a long time to come a uniform railway fare must be considered a Utopia. The only progress which it is possible to arrive at in a given time is that of taking for a standard the railway fares which reconcile, in the best possible manner, the interest of the public with the necessities of the service, and to propose them as an example to less favoured nations. The final object is the same for all the world: facility for travelling at the smaller expense. The invention of railways has solved the first part of the problem; the facility of locomotion has arrived to such a degree of perfection that, with the exception of some ameliorations in the construction of carriages and the comfort of the seats, the travelling public has scarcely anything to desire on that score; the only important problem which remains to be solved is to harmonise as far as possible the prices of transport of the different companies and of all the nations by taking for a model the most moderate tariff, and that which is at the same time the most intelligent one, which takes care of the interests of the public, and protects in the best way the capital employed.

This model tariff neither France nor England can show, for the excessive costs and other useless outlays in the construction and administration of railways necessarily impose upon those countries fares which, far from favouring a free circulation, prevent it on the contrary, by making it impossible to the greater number of people to undergo the expenses of a distant journey. The honour of serving as an example to the whole of Europe belongs incontestably to Belgium, as she was able to bring her railway fares down to a level, which almost may be called one of perfection, and which ensures her the first rank in the competition to be established between the foremost nations of Europe. The following comparative table will serve to judge by:—

FARES OF THE PLACES.

From BRUSSELS to OSTEND.	From PARIS to ORLEANS.	From LONDON to DOVER.
Distance 124 kilometres	Distance almost equal 120 kilometres.	Distance 76 miles or 120 kilometres.
1st 5f. 00c. (4s)	1st 13f. 53c. (10s. 10½d.)	1st 18s. 6d. (23f. 10c.)
2nd 3f. 50c. (2s. 10d.)	2nd 10f. 15c. (8s. 2½d.)	2nd 13s. 6d. (17f. 05c.)
3rd 2f. 50c. (2s.)	3rd 7f. 45c. (5s. 11½d.)	3rd 6s. 6d. 7f. 05c.)

As will be seen the French fares are two and a half times higher than the Belgian. As to the English they are nearly twice as high as those of France, and, consequently, nearly five times as heavy as those of Belgium, a contrast the more salient as England and Belgium are, as regards fuel, by their abundance of coal on nearly even terms. The only extenuation which English railways can plead to excuse the evident exaggeration of railway fares, is the praiseworthy institution of parliamentary trains, as it has been forced upon the companies by Parliament in the interest of the masses. These popular trains, chiefly destined for the working classes, are comparatively cheap; they charge uniformly one penny per mile (10 centimes). But this reduced charge is yet far above the third-class fare in Belgium. It is, therefore, decidedly the Belgians who deserve the palm for facilitating the transport and lowering the fares of the railway traveller.—"Le Credit International."

ON THE CHEMISTRY OF COMBUSTION, &c.*

No. II.

By Mr. W. M. Henderson.

THE tensile strength of good iron boiler plate at 80deg. is about 56,000lb. per square inch. Its tenacity will be increased as the temperature rises, under the conditions of generating steam, up to 550deg. above the freezing point; its maximum strength then is 65,000lb. per square inch. From this it decreases in direct proportion; at double that temperature it loses one-half. As the temperature of the water in a steam-boiler rarely exceeds 400deg. its application to their construction is especially favourable. For the purposes of calculation its average strength may be assumed to be equal to 60,000lb. per square inch. The deduction to be made for single riveted plates is 44 per cent., for double riveted plates 30 per cent., or, ratio, plate being 100: single riveted 56, double riveted 70. From this data, the bursting pressure, equivalent to the ultimate strength of the single riveted joint, is reduced to 34,000lb. per square inch, and the double riveted joint, similarly, to 42,000lb. It is commonly believed the plates are strongest in the direction of the fibre, but experiments have proved they are about 2½ per cent. stronger crosswise of the fibre; it may therefore be safely assumed the strength of boiler plates is equal in all directions. The strength of the plates will be increased by the amount of hammering and drawing through the rolls they receive, and a decided increase of strength will be obtained by cold rolling under pressure. On the other hand, cold hammering is highly injurious, causing crystallization, and, consequently, impoverishing of the material. After such treatment the plates should be re-heated, and allowed to cool slowly, to recover their strength.

The strength of cylindrical boilers subjected to internal pressure varies inversely as their diameters; whilst there seems to be no general rule regarding variations in their length, the strength is affected so slightly that it may be almost entirely disregarded in practice. The strength of cylindrical flues subjected to external pressure varies inversely as their diameters, and also as their length. In the case of the pressure acting internally, the material of the boiler shell is extended equally throughout all its parts, and its cylindrical form is maintained at all stages of the pressure. This is very different when the pressure acts externally; the material being compressed, loses its cylindrical form by crumpling up in longitudinal lines near the middle of its length. This comparatively small portion of the tube then has to resist the main force of compression, since it will be seen the ends of the tube are rigidly held in position by the inflexible heads of the boiler. The pressure producing this collapsing force is always proportional to the longitudinal section of the flue, whilst the part where the collapse will take place is, to a certain extent, independent of the same. To meet this disparity of strength, the flues should be divided into shorter lengths, increasing their strength in uniformity with that of the exterior shell of the boiler by riveting at intervals to the joints T or angle iron rings, or by constructing them entirely of corrugated iron. This equalisation of the powers of resistance of the different parts of a steam boiler is of the utmost practical importance, as any increased strength of the outer shell is of no absolute value so long as the internal flues are liable to be destroyed by collapse at a pressure less than half that required to burst the shell which envelopes them, the extra thickness of metal in the shell being so much material thrown away, adding nothing whatever to the strength.

In the construction of steam boilers, it seems to have been tacitly admitted that the flues, if not the strongest parts, were at least quite equal in strength to the outside shell, and this would appear to be the case, judging by the natural course of analogous reasoning, such flues being of greatly reduced diameters, in proportion to the shell, and generally constructed of the same thickness of plate. It was only from the occurrence of frequent explosion by their collapse that attention was directed to the existing discrepancy, which led to a series of experiments, conducted by Mr. Fairbairn, the result of which established the fact that the flues in the Cornish and double-flue description of boilers were by far the weakest part of the construction, in many cases being only one-third as strong as the outside shell. Another matter developed in the course of these experiments, and one that even now is generally disregarded, is the manner of constructing the longitudinal joints of flues by lapping them over each other; such a departure from the true circle, which can easily be maintained by making a butt joint, with longitudinal covering plates, will impair to a considerable extent their powers of resistance—the loss of strength sustained from this simple matter has been ascertained to be as 7 is to 10, or nearly one-third. In every construction where tubes have to sustain an external pressure, the cylindrical is the only form to be relied upon, and any departure from it is attended with danger.

* Journal of the Franklin Institute.

Elliptical tubes should never be used, as their powers of resistance are reduced in proportion to the amount of departure from the true curve.

In the designing and constructing of steam boilers, care should be taken to so proportion the various parts that they may be, as nearly as practicable, equally strong in every direction. The flues, as has been shown, will require especial attention, being the weakest parts as at present constructed. Flat surfaces are known to require staying, and the necessary strength can be readily secured by calculation. Still after all this a cylinder boiler will be, estimately, just twice as strong, in the longitudinal direction, as in the curvilinear, from a mathematical principle involved in the construction of all cylindrical vessels, i.e., "the areas of circles are to each other as the squares of their diameters." The material offering resistance to rupture in the longitudinal direction being the area of the rim section of the shell, as against the pressure exerted on the area of the boiler head. In the curvilinear direction, it is the area of the longitudinal section of the plates, passing through the axis of the boiler, as against the pressure exerted on the area of the enclosed section. From this, it will be seen that boilers having increased dimensions should also have increased strength in the ratio of their diameters, i.e., one boiler twice the diameter of another should have double the thickness of plates, having to resist double the pressure in the curvilinear direction, and the heads being increased in the proportion of four to one, quadruple the pressure in the longitudinal direction. That this ratio of progression is correct, will be evident by considering that the circumference is doubled with the diameter, and the thickness of the plate also being doubled, gives four times the area of the previous cross section, the power of resistance increasing in strict uniformity with the demand. I have previously stated that the strength of steam boilers, in their longitudinal direction, is estimately twice that of the curvilinear: it would be precisely so were it not for the manner in which many cylindrical boilers are constructed. The shell being composed of short cylinders, formed from one plate, with one row of rivets joining the single lap, here it will be seen one side of the plate remains intact, while where these short cylinders are riveted one to the other, the full percentage of rivet holes are punched, or drilled out, giving an increase of strength in the curvilinear direction equal to about the double riveted joint, reducing the excess of strength possessed in the longitudinal direction from 2 to 1½, and by double riveting the longitudinal seam, this will be further reduced to about 1⅓.

In regard to the strength of the flat stayed surfaces of steam boilers, it has been found, by actual experiments, that at a temperature of 388deg. Fah., or 80lb. steam pressure, it required a force of 8·1 tons to draw out a ¾ iron stay screwed into a ⅝ copper plate, stripping the thread in the latter; 10·7 tons to draw out a ¾ iron stay screwed and riveted into a ⅝ copper plate; and 12·5 tons to draw out a ¾ iron stay screwed and riveted into a ⅝ iron plate.

Ratio iron and iron screwed and riveted	1,000
" and copper " "	856
" " "	648
Copper and copper screwed and riveted	576

Care should be taken to facilitate the uninterrupted ascent of the steam from the point of formation to the surface, with a proper circulation of the water to take its place. Vertical heating surfaces, as the inside box of the locomotive type of boiler, should be so angled that the globules of steam formed thereon may leave such surface on ascending, otherwise the multitude of these globules will form a stratum of steam between the water and the plates, exposing the latter to the danger of burning. The water spaces should be large enough to allow the steam generated to rise to the surface, with space for a down current of water outside, to take the place of that just disposed of. In contracted water spaces, the steam, in formation, drives the water out, preventing circulation, causing, forming, and endangering these parts to overheating and burning out; explosion in such case is only a question as to how long a time it will take to destroy the molecular construction of the plates, by alternately overheating and deluging them with water.

This phenomenon may be seen to perfection in the steaming of many of our steam fire engines, the water will surge and re-surge in the glass gauge, as it is displaced from and returns to the water legs, and it is not an unusual occurrence, after the fire has been withdrawn, for them to continue generating steam in great profusion. The palpable reason for this is, that the water then is allowed to descend into the legs of the boiler, and comes in contact with the superheated plates. An interesting experiment would be, to subject all the boilers of this construction to a test, by inserting a small cock in the outside box, to discover whether or not they are subject to this dangerous practice.

The water spaces, for practical purposes, should be from 2 in. to 4in., according to the size and description of boiler, and thoroughly secured by iron stays, screwed and riveted. In cases where boilers have internal flues, the outer shell will be relieved from a longitudinal strain equal to their area. Ratio of diameter to shell when one is used, as 1 to 2·5, in no case more than as 1 to 2: when two are used, as 1 to 3. When tubes are employed, the distance between them will vary with the calibre, and should be about one-half of their diameter. Where wrought-iron flat heads are used, they should be composed of plates at least one-half thicker than those forming the circumference, and be well secured with corner gusset plates of 45deg., and angle irons radiating to the inside circumference of the shell.

As a rule, no hole should be cut in a steam boiler larger than is absolutely required. Where a steam drum is riveted on it may not be necessary to cut the plate at all; a number of small holes of an aggregate area equal to the steam-pipe or safety-valve is all that is required; and where a man-hole is cut, the margin should be stiffened with strengthening rings, if the frame of the man-hole itself is not sufficiently strong to restore the strength of the plate cut away? Riveted joints exposed to a tensile strain are directly or nearly so as their respective areas, or in other words the collective areas of the rivets should be equal to the sectional area of the plate taken through the line of rivets.

The proportional size of rivets, pitch of ditto, and lap of joint, will be as follows:—Diameter of rivets for plates up to three-eighths is twice the thickness of plate. The pitch for three-sixteenth and one-quarter inch plates is six times the thickness of plate; for five-sixteenth and three-eighth inch plates it is five times. The lap for three-sixteenth, one-quarter, and five-sixteenth inch plates should be six times the thickness of plate, and for three-eighth plates five and a-half times. For double riveting, add two-thirds of the depth of the single lap. Diameter of half round heads one-fifteenth for one-eighth of diameter of rivet. Diameter of conic heads twice the diameter of rivet, and the height of both description of heads, three-fourths diameter of rivet.

As before remarked, the question relating to the strength of cylindrical tubes, when exposed to external pressure, as the flues of steam boilers, requires more than ordinary attention; it has been found by direct experiment that the strength varies in accordance with a certain power of the thickness, the index of which, taken from the mean of the experiments, is 2·19, or rather higher than the square. The formula for calculating the collapsing pressure is as follows:—Where D equal diameter in inches, L length in feet, K thickness of metal, and P the collapsing pressure, then $P = \frac{806800 \times K^{2 \cdot 19}}{L \times D}$

This formula, however, is not of easy solution; by taking 2 instead of 2·19 for the index of K, we get $P = \frac{806300 \times K^2}{L \times D}$ whence the collapsing pressure may be readily calculated by ordinary arithmetic. For thick tubes of considerable diameter and length, it will be found sufficiently exact. For small diameters and short lengths, up to 10ft., the theoretical formula is more correct, but it does not strictly apply to tubes over that length, and when we consider a safe margin is left by allowing only one-sixth for the safe load, the square of the thickness is near enough for all practical purposes.

Rule for calculating the bursting pressure per square inch of a steam boiler in the longitudinal direction. Multiply the area, in square inches, of the cross section of the rim of the boiler, by the value of the iron, as deduced from experiment, and divide by the area of the boiler head.

Formula S = area cross section, C = constant—A = area boiler head, and P = bursting pressure per square inch. Then $P = \frac{S \times C}{A}$.

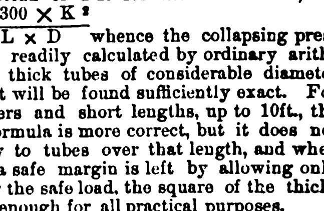
Example.—Given a steam boiler of 34in. diameter, with single riveted joint, and constructed of quarter inch plates. To find the pressure per square inch, that will tear the shell apart, in a longitudinal direction. Here the sectional area of the rim is equal to 18·66 square inches, the value of the iron for the single riveted joints is 34·000 per square inch, and the area of the boiler head is 452·39 square inches.

Then $\frac{18 \cdot 66 \times 34 \cdot 000}{452 \cdot 89} = 1{,}502 \cdot 4$lb. which is the bursting pressure per square inch.

Rule for calculating the bursting pressure of a steam boiler in the curvilinear direction. Multiply the area in square inches of the section of the plates taken through the axis of the boiler by the value of the iron, as deduced from experiment, and divide by the diameter of the boiler.

This will be better understood by reference to the

FIG 1.



foregoing diagram, representing a section of a steam-boiler, the pressure acting as indicated by the arrows, the resisting material being the side of the boiler T T. It is obvious the length is quite immaterial, a hoop of 1in. in length will give us all that is necessary to make the calculations, that 1in. being equal in effect to any other inch or aggregate number of inches, when multiplied by any such length taken.

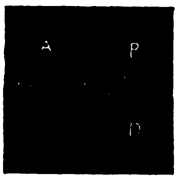
Formula.—Let T = thickness of plate, C = constant, D = diameter, and P = bursting pressure. Then $P = \text{twice}\ \frac{T \times C}{D}$.

Example.—Taken the same boiler, as given above, to find the bursting pressure per square inch, that will rupture the shell in the curvilinear direction. Here T = 25in. The two sides = 5in. The value of the iron as before, 34,000lb. per square inch, and the diameter is 24in.

Then $P = \frac{5 \times 34000}{24} = 708{\cdot}33$, which is the bursting pressure per square inch for the safe load, allow only one-sixth of the bursting pressure. It will be seen by comparing the results of these calculations that the boiler is, as before stated, twice as strong in the longitudinal as it is in the curvilinear direction.

The manner for proceeding to calculate the strength required in flat stayed surfaces of a steam-boiler will be readily understood by an inspection of the following diagram, showing the general arrangement of such staying, and the surface of pressure each stay has to sustain. It will be observed that the distance from the centre of one stay to the next, forming a square, is the only measurement of surface necessary to be calculated, each square of the entire surface being alike, and assuming this rectangle to be situated as shown by the figure A B C D,

FIG. 2.



we find that the whole of the pressure bearing upon this surface has to be sustained by the single stay S. All that remains then to be done, is to so proportion the area of this rectangle in reference to the pressure of steam to be employed, and to make the cross section of the stay, at the smallest part, strong enough to bear six times the pressure that will be brought to bear upon it, taking the ultimate tensile strength of iron stays at 60,000lb. per square inch, and assuming that such stays are screwed and well riveted on both sides. The additional strength secured by riveting the stays has been found to be about 14 per cent.

Safety valves—allow one square inch area of safety valve per each 3 square feet of grate surface. Calculations for the safety valve.

First. When the lever is parallel, multiply the weight of the lever by half the number of leverages. If the lever is not parallel, balance it upon a fulcrum and multiply the weight as before, by the number of leverages contained up to the point of balance, add the weight of the valve and attachments, and divide this product by the area of the valve in inches. The result will give the weight per square inch upon the valve seat, from the effect of the lever and valve, &c., alone. This is a constant weight entirely distinct from the effect produced by the sliding weight of the ball, which will vary with its position on the lever.

Second. Divide the weight used by the area of the valve in inches; this will give the direct weight per square inch, supposing it to be placed immediately over the valve; if it is placed upon the second notch, it will be twice as much; if upon the third notch, three times as much, and so on, depending upon the point of location distant from the fulcrum. Wherever it is placed, divide such distance from the fulcrum by the distance from the fulcrum to the centre of the valve; this will give the amount of leverage by which to multiply the direct weight previously found. The constant weight must always be added at all points where the lever is required to be marked, or the weight to be ascertained.

There is little further to add to this subject of steam boilers, rendered as brief as possible, commensurate with the extent of information attempted to be conveyed; if not, therefore, generally instructive, it will, at all events, like a short sermon, not prove tiresome to the reader.

One other item, without which the boiler is not complete, is the chimney, which we will now briefly dispose of. The draught or current of air passing through a furnace is occasioned by the difference in weight between the column of rarified air within the chimney and that of an external column of the same proportion. The area of the chimney or smoke stack, as already given, should be about two square inches per pound of coal consumed per hour, or twenty-four square inches per square foot of grate surface. The length should be about one yard per inch of the diameter. The general practice of decreasing the area towards the top is an error; they should be constructed of at least an equal area throughout; for, although it is true that the volume of the heated gases diminishes as they leave the furnace, the velocity is also proportionally reduced.

ON THE SUN.*

BY MR. NORMAN LOCKYER.

THE lecturer said that thousands of generations of men had flitted over our planet before the idea that the sun was the nearest fixed star was seriously discussed; indeed, men were still living, who had finally settled the question. This fact illustrated in full force the importance of a study of the sun, for if the sun was merely the nearest fixed star—brighter and bigger looking than the rest on account of his nearness—we must look upon him as a specimen of the millions of other stars, more remote, which together formed what might be called the skeleton of the universe—the scaffolding which doubtless supported other systems like our own, and other habitable worlds past, present, and to be. Galileo and others, with the first-made telescope, attacked the sun, and endeavoured to wrest some of his secrets from him. They found that the surface, which till then had been regarded as of spotless purity, had spots upon its surface; and after the first excitement of the discovery had worn off they determined the rotation of the sun upon its axis, like that of the earth, by them. This discovery was completed, and in 1769 Dr. Wilson discovered that the dark spot was below the brightly shining apparent surface called the photosphere. Sir Wm. Herschel, too, interpreted the darkest central portion of the spot to be a portion of a cool, habitable globe, a fitting abode for man, and reachable through a rent in the photosphere, from the light and heat of which the inhabitants were effectually screened by a highly reflective envelope suspended midway between the photosphere and the globe itself.

This theory had been much contested, and, during the last decade, an instrument much more searching than the telescope had been brought upon the field, and we learned that the sun and every star, so far from being cool and habitable, were glowing with the fiercest heat. This was the prism, or number of prisms so arranged as to form what was called "the spectroscope," an instrument which tells the composition of the light given off or radiated by bodies when they are burning or glowing—that the light radiated from different bodies gave spectra of different kinds, according to the nature of the radiating body. Dr. Wollaston, many years ago, discovered that the spectrum, or sun's light, was not a continuous one, but that it was crossed by black lines indicating reflective absorption of the light. Professor Stokes and Mr. Wm. Thompson found that a double absorption line in the sun's spectrum corresponded with a double absorption line in the spectrum of the light radiated by incandescent sodium vapours. They suggested that this might indicate the presence of sodium vapour round the sun absorbing its otherwise continuous spectrum. This had been established since by Kirchoff and Bunsen, who further showed that the light of the sun was being absorbed by the vapours of sodium, iron, magnesium, varium, &c.

According to the new theory of the sun, founded by Kirchoff and Bunsen, the photosphere was a liquid sea of molten substance, and over this was a transparent atmosphere, containing the vapours to the absorption of which the lines are due. The spots are merely opaque clouds cutting off the light from the molten sea. This theory did not satisfy astronomers in all particulars. They did not accept the theory that the spots were clouds above the photosphere, nor that the photosphere itself was liquid, for the evidence of the telescope that the former are cavities in the photosphere is overwhelming, and the changes in the light are so great, and its general appearance so cloud-like, that the assertion as to its being a liquid seemed to be contrary to the evidence. The theory of an enveloping atmosphere was accepted on all sides, and was supposed to cause the phenomenon of a halo of light, seen in eclipses, and called "the corona." Since the theory of Kirchoff and Bunsen was given to the world, two others had been proposed. Messrs. De la Rue, Stewart, and Loewy, representing English science, said that a spot is dark because the solar light is absorbed by the cool non-luminous atmosphere pouring down there on to the visible surface of the sun, in other words, on to the photosphere. M. Faye, representing French science, said that a spot is dark because it is a hole in the photosphere, and the feebly luminous, and therefore radiating, interior of the gaseous sun is there alone visible. Here was a clear issue which probably nothing but the spectroscope could solve.

The lecturer then examined and explained the various experiments which had been recently made in the more systematic and thorough examination of the sun by himself and other physicists; and he also explained the spectra of the sun during an eclipse, as well as the instruments by which they were taken, and the principles on which they were constructed for observing the sun in particular spots of its surface. The results obtained by Dr. Frankland, Dr. Balfour Stewart, and himself, had, as early as 1866, referred the strange red flames seen in an eclipse to masses of gas. An instrument was ordered by which to observe them, and this could not be obtained and the theory confirmed till after the eclipse of 1868 had been observed. The result was to prove that the red flames seen in an eclipse are composed mainly of hydrogen, and the instrument invented by the lecturer enabled astronomers to observe them without waiting for an eclipse.

Storms were frequently to be detected on the sun, and they were very easily observed by the new apparatus. The lecturer's calculation of the up and down rush of hydrogen in these storms was forty miles a second, while the velocity of lateral, or cyclonic movement, was 120 miles a second, and these numbers would give an idea of the enormous forces at work on the sun, and explain the rapid changes and intense action visible in the spots. The lecturer exhibited some beautiful spectra of the sun to show that the pressure of the sun's atmosphere increased in proportion as the tops of the protuberances were observed or the lower points to which the vapour reached, and said that the conclusion as to the nature of the sun to be drawn from all these experiments was, that the sun was a star, with a nucleus giving a continuous spectrum, surrounded by an atmosphere absorbing that spectrum, the photosphere—the visible star—being situated in that atmosphere. Fundamentally, their theory was the same as Kirchoff's, but there were very important differences. The lecturer had showed that the brilliant photosphere, instead of being a sea of molten metal, the continuous spectrum of which is absorbed by an enormous atmosphere outside it, is part and parcel of the atmosphere of the sun, and is situated actually above the region in which most of the absorption takes place.

The lecturer then glanced at the results of the observations of other stars by the method employed to observe the sun, one of which was to show that the term "worlds on fire" needed not be applied to some of the stars, as the phenomena they exhibited could readily be explained by what had been observed in connection with the sun. Sir William Herschel and Laplace's theory, as to the nebulæ, that they indicated the presence of a nebulous fluid in space, had been confirmed by the brilliant discovery that they were, in the main, masses of hydrogen gas. Dr. Frankland and himself had also been enabled to ascertain, by the spectrum analysis, that they existed in a state of the greatest rarefaction, and that their temperature is very much below that of the very last stratum of the sun's atmosphere. These were some of the results of the past year's workings, and it was to be hoped that there might soon be more workers to dig in this mine, for we might rest assured that the present results would soon be left far behind, and the future lectures of the British Association would tell of other pages in the book of nature, so beautiful, so brilliant, that the one he had read to them would pale its ineffectual fires, for now

"Science reaches forth its arms
To feel from world to world, and charms
Her secret from the latest moon."

The lecturer's explanations were very clear, and the experiments remarkably successful. The spectroscope was so arranged as to throw the spectra upon a canvas screen, and instances of absorptive and selective light were shown. The illustration of Frauenhofer's lines—indicative of the presence of sodium—was very fine and clear, as was also the representation of the *corona* and red protuberances which were first observed in the eclipse of 1706. The method of observing particular parts of the sun's surface—"taking the sun to bits," as the lecturer expressed it—was explained by throwing upon the screen a picture of the solar telescope, prepared with the slit so as to afford observations of different portions of the sun's surface. The different lines indicating the presence of hydrogen were all shown and explained. Another photograph, showing the protuberances seen outside the sun, was very beautiful, and the lecturer explained that they were caused by the vaporous atmosphere of the sun, some of them being nearly 28,000 miles high. A series of photographs were shown to illustrate what Mr. Lockyer has very properly called "solar storms," for he has calculated that the velocity of the vapour on the sun's surface ranges at such times from 40 to 120 miles per second. The method by which this was ascertained was beautifully and clearly exhibited in a series of photographs, by the deflection of the lines in the spectrum. The method by which the nature of the sun's atmosphere had been analysed and examined formed another interesting set of illustrations.

* British Association.

SENATOR SPRAGUE is said to be the largest employer of labour in the United States. He gives work to about 8,000 persons, and has recently raised their wages fifteen per cent.

WEEKLY CHEMICAL, MINERAL, AND METAL REPORT.

(From J. Berger Spence & Co.'s Manchester Circular, October 14.)

CHEMICALS.—With the commencement of the new quarter a satisfactory business has been done in this market in chemicals generally, and excepting one or two specialities of the trade, manufacturers have no reason to complain. The alkali trade does not yet show any signs of increased vitality, and unless some extraordinary demand for shipment should spring up, or the present overproduction is further reduced, producers must still submit to present unremunerative prices. Soda: prices remain the same for soda ash, with a limited home demand, at £7 to £7 7s. 6d. for 48. Crystals dull at £4 5s. Caustic, offered freely, at £13 10s. Bicarbonate, in moderate request, at £9 10s. Nitrate of soda: is steady, at £17, for immediate delivery; to arrive, business is done at £15 15s. Potash: muriate remains firm at £7 7s. 6d. for 80; present contracts will take up the bulk of the production until the end of the year. Saltpetre: foreign is disposed of freely at 23s.; English, steady at 27s. 6d. Alum: no change in prices, the demand being good, chiefly for the paper makers; prices are firmer, at £6 5s. for home, and £7 for export. Ammonia: sulphate is nearly all bought to December, and £16 10s. is asked for inferior lots. If nitrate soda maintains its price, no reduction in quotation for sulphate of ammonia will occur. Copperas: the market is unchanged. Green, 52s.; dry, 50s.; chloride of iron firmer, at 52s. Pyrites: a moderate business in Norwegian at 7½d. per unit. No change in Spanish. Calcined pyrites is offered at 44s. 6d., returning charges for copper. Lime: the transactions in phosphate have been moderate at previous prices. Bleaching powder in better demand at £8 2s. 6d. for 35. Disinfectants meet with a ready sale at £5 5s. per ton for farmers. Manganese: considerable contracts have been concluded for high percentages at 95s. to 97s. 6d.

METALS.—The past week has been an inactive one in metals, and prices generally remain about the same as quoted in our last report. Iron: Scotch pigs keep steady at 53s. 1d. to 53s. 3d. Cleveland, firm at 43s. for forge to 48s. 6d. for No. 1. Welsh bars, £6 5s. to £6 7s. 6d.; Staffordshire, £6 10s. to £7; gas tubes at 60 to 70 off list; boiler tubes, 40 to 45. Copper: very little business doing in copper, except for braziers' sheets, for which some good orders have been given out for India lately. Prices are for tough ingot, £72 to £73; and for Chili slab, £67 to £68. Tin is firm at present quotations. Straits, £129 to £131; English, £125 to £126. Lead: a moderate business has been done for export, English soft pig selling at £19 to £19 5s.; P. G. brand, £18 10s. Spelter is very quiet. English firm at £20 15s. to £21 5s.; Silesian, special brands, £20 5s. to £20 10s.; hard spelter, for export, £16 5s. to £16 10s.

TO CORRESPONDENTS.

THE MECHANICS' MAGAZINE is sent post-free to subscribers of £1 1s. 8d. yearly, or 10s. 10d. half-yearly payable in advance.

All literary communications should be addressed to the Editor of the MECHANICS' MAGAZINE. Letters relating to the advertising and publishing departments should be addressed to the publisher, Mr. R. Smiles, MECHANICS' MAGAZINE Office, 166, Fleet-street, London.

To insure insertion in the following number, advertisements should reach the office not later than 5 o'clock on Thursday evening.

We must absolutely decline attending to any communications unaccompanied by the name and address of the writer, not necessarily for insertion, but as a proof of good faith. ED. M. M.

Advertisements are inserted in the MECHANICS' MAGAZINE, at the rate of 6d. per line, or 5d. per line for 13 insertions, or 4d. per line for 26 insertions. Each line consists of about 10 words. Woodcuts are charged at the same rate as type. Special arrangements made for large advertisements.

Meeting for the Week.

MON.—Society of Engineers.—Mr. Perry F. Nursey on "English and Continental Intercommunication," at 7.30 p.m.

Naval, Military, and Gunnery Items.

THE "Leander," the second of the clipper tea ships, arrived off the Scilly Islands this day week.

WE regret to observe that the death is announced of Mr. Thomas Wingate, the oldest engineer and shipbuilder on the Clyde.

A NOTIFICATION has been received at the Portsmouth Dockyard that the usual annual examinations of the different trades for promotion is not to be held as usual this year, and that it will not take place unless further orders are issued. The examination has usually been held in the first week of December of each year.

THE tonnage for the port of Hull for the nine months of the present year is 1,055,677, being about 10,000 tons in excess of the corresponding period of last year, which was one of the most prosperous years the port ever had.

THE Board of Trade have awarded a telescope to Captain A. D. Larsen, of the Norwegian vessel "Bien," of Krageroe, in acknowledgment of his humanity and kindness to the shipwrecked master and crew of the "Prima Donna," of Hull, whom he received on board his vessel on the 7th September, 1869, in latitude 55·40 N. and longitude 1·18 E.

DURING the month of September twelve vessels were launched from Clyde shipbuilding yards. Four of the number were iron screw steamers, and the remaining eight iron ships. The total tonnage was over 13,000 tons, the two largest vessels being of 1,385 and 1,380 tons respectively. Five of the launches were at Glasgow, three at Port Glasgow, two at Dumbarton, and two at Greenock.

THE Colonial Office has issued the casualty roll of the Europeans killed and wounded by the rebel Maories between June 1, 1868, and August 1, 1869. It is to be understood, however, that it is the best account of the casualties that can be obtained, but it is feared that it is not quite complete or correct in all particulars. The total is a very serious one, viz., murdered, 47 and 18 children; killed in action, &c., 96; and wounded, 98.

THE Pacific Steam Navigation Company of Liverpool have just contracted with the shipbuilding and engineering firm of the late John Elder, of Govan and Glasgow, which continues its extensive operations, for an additional steamship of 3,088 tons and 550-horse power, for the Liverpool and Valparaiso mail service. The engines will be the 25th pair on the "compound" principle, of which the company have long had favourable experience.

ON the 3rd inst. the screw corvette "Elizabeth" set sail from Dantzic. She is to proceed to England, and afterwards to take up the Prussian scholars of the Egyptian expedition, and start for the East. The Crown Prince will sail on board her as far as Alexandria, and then make use of the "Grille." Two hundred men have been added to the crew, which now numbers 500, the nominal strength in time of war.

LAST Friday night's "Gazette" contains regulations with reference to the pensions payable by the Board of Trade to masters and seamen who contributed sixpence a month towards the support of Greenwich Hospital. To be qualified for pensions applicants must prove at least five years' service prior to January 1, 1835; they must not be under 55 years of age, and must have been disabled or incapacitated from age. The amount of each pension is limited to the sum of £3 8s. a year. The whole sum applicable to these pensions, and paid by the Admiralty to the Board of Trade, is £4,000 per annum.

IT is said that a corps of volunteers is to be formed at Rome consisting entirely of nobles. At present only 500 have enrolled themselves, and, as the corps is to be 800 strong, 300 more are required. The members are not limited to the Roman nobility, but may be of any nation. The command will be given to a Lieutenant-Colonel taken from the army. The uniform is described as handsome. The members of the corps will not receive any pay, and their duty will consist in guarding Rome. There does already exist a Palatine Guard, whose duties are the same, but this guard is composed of shopkeepers, though they, too, give their services gratuitously.

ONE of the smallest screw steamers that ever crossed the English Channel at this season of the year arrived in the Cork harbour on Wednesday week from Cowes. She is named the "Cuckoo," and manned by Captain Wakely, John Groves, engineer, and Frederick Vincent, seaman. She is an open screw steamboat, of about 2½ tons, has a temporary covering over the coal locker, and a small saloon, a stern capable of only admitting four persons to sit in, has no cooking accommodation, nor any berths. The crew were obliged to take such stock of prepared food as was necessary for the voyage, and they did not change clothes since they left Cowes on the 7th of September.

NUMEROUS inquiries have reached the "Army and Navy Gazette" asking why the New Zealand medal has not yet been issued. Six months ago the medals were finished casting, &c., by the Mint; the ribbon (a very appropriate one) decided on and approved by His Royal Highness the Commander-in-Chief, and, we believe, by her Majesty; the lists of the names of candidates sent into the Admiralty and Horse Guards, and yet no issue! Rumour says that the fact of the Commander-in-Chief having approved of the ribbon before it was approved by the Home Department in the War Office has offended a clerk in the department, and Bumbledom has determined that the ribbon shall be altered, and so has stopped the issue. Fortunately a sample of the approved ribbon is in the possession of an influential member of parliament, and should any alteration be attempted he is determined to sift the matter to the bottom.

Miscellanea.

THE Harvest Fête given on Monday last at the Crystal Palace with such success will be repeated, with display of fireworks, on Monday next, the great trophies and other decorations remaining until then.

THE number of visitors to the Patent Office Museum, South Kensington, for the week ending October 9, was 5,452. Total number since the opening of the Museum, free daily (May 12, 1858) 1,662,657.

A CORRESPONDENT writes us that Sir Titus Salt has recently had expansion valves fitted to the whole of his steam engines at Saltaire—six in number—the result being a saving of 50 tons of coal per week!

THE Government of India has made arrangements for having a cast taken of the principal remaining gateway of the Sauchi Tope, near Bhilsa, with a view of having produced several copies of this work, the date of which is supposed to be about 250 B.C. It is the most elaborate work of sculpture existing in India.

MR. WOODWARD, librarian in ordinary to the Queen at Windsor Castle, died on Tuesday night. Mr. Woodward was a man of considerable literary and artistic culture. He wrote a history of Wales, and a history of America, and a local history of Hampshire, was editor of the "Fine Arts Quarterly Review," and was lately engaged on a life of "Leonardo da Vinci."

THE number of visitors to the South Kensington Museum during the week ending October 9, 1869 was—on Monday, Tuesday, and Saturday (free), from 10 a.m. to 10 p.m., 15,692; Meyrick and other galleries, 2,095; on Wednesday, Thursday, and Friday (admission 6d.), from 10 a.m. till 5 p.m., 2,110; Meyrick and other galleries, 294; total, 20,191. Average of corresponding week in former years, 13,006. Total from opening of Museum, 8,868,402.

THE imports of iron minerals into France in the first seven months of this year have been officially returned at 336,392 tons, of which 130,499 tons came from Algeria. The Belgian iron trade continues active: great efforts are being made by the Belgian works to increase their means of production; the Thy-le-Chateau Company proposes, for instance, to double its annual make of rails. Under these circumstances it will be inferred that prices display considerable firmness in Belgium. The extraction and consumption of coal are increasing in Belgium.

THE "Saint Louis Republican" records the death of Archibald W. Oxendine, another "Last Man," who was born on Pedee River, South Carolina, August 29, 1759, and died at Benton's Creek, Phelps County, September 3, 1869. He served throughout the war of the Revolution as one of "Marion's men." For over 40 years he was a Baptist minister. He had been unable to walk for the last three years, but retained his sight, hearing, and intellect up to his last hour. He was attended in his last illness by his youngest daughter, over 70 years of age.

A CORRESPONDENT, writing from Auckland by the last mail, says:—"I fear we are being carried away by an extraordinary flow of commercial prosperity. Our Thames gold fields are literally flooding us with wealth. The returns are likely to be from 25,000oz. to 40,000oz. per month during the next six months, worth (say) fifty shillings per ounce. This amount will necessarily cause a great increase of trade and confer a benefit on a large portion of our population, while numbers are becoming suddenly rich. At present we do not see any great increase of public immorality, but I fear the tendency will be in that direction."

THE imports into the colony of Victoria in 1869, to August 7, amounted in value to £8,125,208, an increase of £947,632 over the amount for the corresponding period of 1868. But the "Melbourne Argus" reports that the markets are very much glutted with merchandise, and importers will have to submit to unsatisfactory prices for a little while yet, before the markets begin to recover. The exports have amounted in value to £7,276,918, showing a decrease of £1,413,636. Hopes were entertained of better prices for wool, and an increasing demand for preserved meats in the home market.

ACCORDING to the "Rangoon Gazette," a discovery has been made by a European gentleman resident in Maulmain, which may eventually become of great importance to the place. Near the Damathat caves he has found a certain description of clay, which when mixed with certain proportions of sand, water, and other substances, possesses all the properties of the best Portland cement. It can be produced in any quantity at about one-fourth of the cost of the latter article. We believe the chief engineer has given every encouragement and all the assistance that lay in his power to the discoverer. We trust the latter gentleman may make a rapid fortune out of the new cement.

THE reports received from the French metallurgical districts—the Haute Marne, the Moselle, the Meurthe, the Ardennes, the Nord, &c.—are of a satisfactory description, some difficulty being experienced in executing the numerous orders received. Iron is well maintained in price; rolled from coke-made pig is quoted at St. Dizier at £8 4s. per ton; mixed rolled iron (merchants' bars) at £8 12s. to £8 16s. per ton; and rolled iron from charcoal made pig at £9 4s. per ton. The foundries of the Haute Marne are well employed, the forges and foundries of the Moselle and the Meurthe also display considerable activity. The Moselle and the Meurthe works have even been obliged to transfer some orders to the rolling mills of the Ardennes.

MR. W. I. TRAFTON, of Manchester, U.S., who has already made one miniature steam engine of great delicacy and beauty, is about to construct another. He is to make every part of the engine, with the boiler, from a single silver half-dollar. The "Scientific American" states that when done it will be placed under a glass case ¾in. in diameter and 1¼in. in height. The boiler will hold about 8 drops of water but one-half that quantity will run it several minutes. It will have all the parts of an engine, and the boiler will have two minute gauges. Some of the smaller parts can only be made by the aid of a powerful magnifying glass.

THE "Lounger" of the "Illustrated Times" says:—By the way, touching waterproofs, I think I can give travellers a valuable hint or two. For many years I have worn indiarubber waterproofs, but I will buy no more, for I have learned that good Scottish tweed can be made completely impervious to rain, and moreover, I have learned how to make it so; and, for the benefit of my readers, I will here give the recipe:—In a bucket of soft water, put ½lb. of sugar of lead and ½lb. of powdered alum; stir this at intervals until it becomes clear; then pour it off into another bucket and put the garment therein, and let it be in for 24 hours, and then hang it up to dry without wringing it. Two of my party—a lady and gentleman—have worn garments thus treated in the wildest storm of wind and rain without getting wet. The rain hangs upon the cloth in globules. In short, they are really waterproof. The gentleman, a fortnight ago, walked nine miles in a storm of rain and wind such as you rarely see in the south; and when he slipped off his overcoat, his under clothes were as dry as when he put them on. This is, I think, a secret worth knowing; for cloth, if it can be made to keep out wet, is in every way better than what we know as waterproofs.

Patents for Inventions.

ABRIDGED SPECIFICATIONS OF PATENTS.

THE Abridged Specifications of Patents given below are classified, according to the subject to which the respective inventions refer, in the following table. By the system of classification adopted, the numerical and chronological order of the specifications is preserved and combined with all the advantages of a division into classes. It should be understood that these abridgments are prepared exclusively for this Magazine from official copies supplied by the Government, and are, therefore, the property of the Proprietors of this Magazine. Other papers are hereby warned not to produce them without an acknowledgment:—

BOILERS AND FURNACES—824, 830, 848, 850, 877
BUILDINGS AND BUILDING MATERIALS—869, 879, 884
CHEMISTRY AND PHOTOGRAPHY—819, 858, 870, 881
CULTIVATION OF THE SOIL, including agricultural implements and machines—826, 859, 883
ELECTRICAL APPARATUS—888
FIBROUS FABRICS, including machinery for treating fibre pulp, paper, &c.—823, 846, 865, 871, 874, 894, 899
FOOD AND BEVERAGES, including the apparatus for preparing food for men and animals—847, 856
FURNITURE AND APPAREL, including household utensils time-keepers, jewellery, musical instruments, &c.—817, 843, 844, 851, 855, 866, 873, 876, 878, 880, 891, 898
GENERAL MACHINERY—822, 852, 857, 868, 900
LIGHTING, HEATING, AND VENTILATING—820, 827, 831, 832, 845, 849, 887
METALS, including apparatus for their manufacture—836
MISCELLANEOUS—841, 847, 858, 860, 862, 872, 875, 882, 886, 887, 890, 893
ROADS AND VEHICLES, including railway plant and carriages, saddlery, and harness, &c.—834, 837, 842, 863, 864, 885
SHIPS AND BOATS, including their fittings—828, 835, 840, 867, 889
STEAM ENGINES—818, 829, 854, 861
WARFARE—821, 825, 838, 839, 893, 896, 897

817 F. GILLHAM, Liverpool. *Hats.* Dated March 17, 1869.

This consists in making the bands of elastic ventilating soft material, preferably vulcanised indiarubber, or other elastic material capable of being moulded or otherwise formed. These bands it is proposed should run round the interior of the front of the hat and extend backwards on each side about one-third of or all round the circumference, and it is preferred that they should be from 1in. to 1½in. in width, and about ¼in. thickness.—Patent abandoned.

818 J. H. BENNETT, Leith. *Steam engines.* Dated March 17, 1869.

This relates, first, to an improved construction of surface condensers for steam engines; second, to certain peculiar constructions and arrangements of frictionless slide valves; and third, to certain peculiar constructions and arrangements of high pressure steam boilers or generators and their furnaces.—Patent completed.

819 C. F. CLAUS, Middlesborough-on-Tees. *Carbonate of potash.* Dated March 17, 1869.

This consists, first, in the manufacture of carbonate of potash by the action of carbonic acid derived from various sources, either pure or mixed with other gases, upon solutions of sulphide of potassium obtained either by the decomposition of solutions of sulphate of potash, by means of solutions of sulphide of barium, or by the reduction at a high temperature of sulphate of potash by means of carbonaceous materials (such as coal, coke, or charcoal or other analogous substances), and by dissolving the sulphide of potassium produced in water.—Patent completed.

821 J. RAMSBOTTOM, Crewe. *Ventilating tunnels.* Dated March 18, 1869.

This consists in extracting the vitiated air from the tunnel through one or more openings, at or near the middle of its length, by means of fans or pumps, or by the rarefaction of the air by heat in an upcast shaft as is practised in mines. The vitiated air so exhausted is replaced by fresh air from each end of the tunnel.—Patent completed.

821 T. MARTIN, Formby, Lancashire. *Supplying ammunition.* Dated March 18, 1869.

A light hand car or truck accompanies the troops into action, which may contain any amount of ball ammunition, say 1,000 rounds, which can be conveniently transported therein. By this means, greater confidence will be imparted to the men, and rapid and useless firing off of ammunition will be prevented.—Patent completed.

822 G. R. MATHER, Wellingborough. *Cutting wood.* Dated March 18, 1869.

This relates to the use of stone, artificial stone, or other gritty composition, adapted to cut into wood and give form thereto. For this purpose, the natural or artificial stone or composition is fitted to a spindle which is caused to revolve, and the form desired to be given is produced as a counterpart on the edge or other surface of the stone or composition. The wood to be cut, if of contiguous length as in the case of mouldings, is conducted by guides to the surface of the revolving stone or composition.—Patent completed.

823 J. C. RAMSDEN, Bradford. *Looms.* Dated March 18, 1869.

The inventor dispenses with the shuttles and feeds in the weft from each side by means of needles. The bobbins upon which the weft is wound can be of any suitable size, and fixed at any convenient part of the loom, care being taken to fix them in that position in which the yarn or weft will come off with the least friction or drag.—Patent completed.

824 E. BOOTH, W. P. GAULTON, and J. WALLS, Manchester. *Admitting air to steam boilers.* Dated March 18 1869.

This consists in applying an apparatus formed by an elastic diaphragm or by a pair of bellows or by an apparatus somewhat similar to a small gasometer, sealed with mercury or other fluid, to act as a pump to draw in or expel air through a suitable valve. This air is again driven out or drawn in again slowly through a small orifice regulated by a tap or valve. Such an apparatus as one of those above referred to may be mounted upon the furnace door and connected directly, or by levers, and rods or chains, with a "grid" or other valve in the fire-door, which valve is lifted to open the orifices for air when the furnace door is open or latched, the latch of the door forming a lever for the purpose. The act of opening the air valve draws in or expels the air (as the case may be) from the apparatus above referred to, and this causes the valve to be held open, while the slow admission of air to the apparatus allows the valve gradually to shut and cut off the supply of air.—Patent abandoned.

825 J. H. JOHNSON, Lincoln's Inn-fields. *Firearms and cartridges.* (A communication.) Dated March 18, 1869.

This consists, first, in making the bore of small arms (whether for military or sporting purposes) and ordnance oval, but without any twist, the object being that when using small shot, or when more than one ball is employed, to scatter the shot in the most serviceable direction. In military arms the major axis of the bore should be horizontal, so as to disperse the shot in a horizontal line, but in double-barrelled sporting guns one of the barrels is placed above the other, and the major axis of one bore coincides with the minor axis of the other.—Patent abandoned.

826 J. T. DARKE, Walton-on-Thames. *Manure from sewage.* Dated March 18, 1869.

This consists in receiving the sewage on a filtering fabric supported by a perforated surface, the fabric being adapted for arresting the more solid parts of sewage matter, and allowing the liquid sewage to pass away through the perforations below the fabric. The sewage matter arrested by the filtering fabric is treated with dry earth or other deodorising and disinfecting substance.—Patent abandoned.

827 A. DE PINDRAY, Paris. *Smoke-consuming apparatus.* Dated March 18, 1869.

This relates to improvements in the construction of the furnaces of steam boilers, at the same time ensuring an entire consumption of smoke. First, by an improved combination of the apparatus at present employed, which are modified to obtain the result desired. Second, by the particular arrangement of the furnace and boiler and the disposition of the same one with the other for utilising the whole of the available heat. Third, by the particular form and dimensions of the fire-grates, flues, and other parts, which vary with the horse power and form of the boilers and the fuel employed.—Patent completed.

828 W. R. LAKE, Southampton-buildings. *Anchors.* (A communication.) Dated March 18, 1869.

This consists in an anchor made with the palms of its flukes in the same plane, and with the arms of its flukes made integral with an open yoke, across which extends, from one side to the other, in the same plane with the palms and arms of the flukes, a pin shaft or pivot integral with the yoke, the shank being entered within the yoke, opening and grasping the cross shaft in the yoke in the manner of a machine bearing.—Patent completed.

829 A. and S. HAYCRAFT, Stroud, and S. HAYCRAFT, Birmingham. *Steam engines.* Dated March 18, 1869.

This consists in so constructing and arranging the parts of stationary, locomotive, and marine steam engines as to effect a more economical use of steam than in steam engines of the ordinary construction. This is effected by arranging the valves and gearing of the engine in such manner as to keep steam from the boiler continuously on one side of the piston, the motive steam from the boiler, or that steam by which motive power is produced, acting on the other side of the piston.—Patent abandoned.

830 J. PARTINGTON, jun., Oldham. *Smoke consumer.* Dated March 18, 1869.

The inventor makes or leaves apertures or openings at the lower part of the front of the bridge wall. From these openings holes or passages lead to the top of the bridge through the bridge wall, or passages may be formed leading directly from the front part of the wall below the firebars to the top of the bridge. Cold air enters the apertures or openings at the lower part of the bridge wall, and is caused to pass through the passages leading out at the top of the bridge by the draught of the chimney or other well-known means.—Patent abandoned.

831 W. T. SUGG, Vincent-street, Westminster. *Gas burners.* Dated March 18, 1869.

This consists in the delivery of the gas into the chamber containing the aperture or apertures at which ignition takes place at a low velocity and a temperature exceeding that of the surrounding atmosphere as little as possible, and in so arranging the sizes and shapes of the tubes or channels and orifices that the gas shall issue at the point of ignition at an inapplicable or the least possible pressure.—Patent completed.

832 A. B. WALKER, Liverpool. *Producing and applying heated air.* Dated March 18, 1869.

The inventor uses a stove of the following peculiar formation. He has a tube of copper or other suitable material, of a broad flat form (sectionally), coiled like a helical spring. This he encloses in a case of metal or firebrick, placed over a fire, the flame of which passes up through the spaces formed in the coil between the tubes. The air to be heated is driven by a fan or any other form of blowing machine, through the inside of the tube forming the coil in which he places tines or obstructions, so as to break up the current of air and bring each particle of it in contact with the heating surface of the tube, thereby ensuring a more perfect heating of the whole body of air than can be obtained by passing it through a plain tube. The inventor uses gas alone for heating the coil, and sometimes, by preference, when the air is not required to be highly heated, places the coil inside of a steam boiler.—Patent completed.

833 J. RITCHIE, Leicester-square, Westminster. *Flywheels.* Dated March 18, 1869.

The inventor makes flywheels or other similar constructions in the form of hollow circular cases of iron, earthenware, porcelain, or other materials, with an opening or openings provided with means of closing the same to admit of the insertion and the emptying of water or other fluid or weighting body to increase the power of rotary or other motion.—Patent abandoned.

834 J. COX, Gorgie Mills, Edinburgh. *Velocipedes.* Dated March 18, 1869.

The inventor proposes to attach levers by connecting rods to the cranks of the guide wheel, and fastens them to the shears, fork, or frame in which the wheel is fitted and revolves, so that all the propelling parts turn or revolve with the shears, and keep in proper position in relation to the wheel. According to the angle of inclination at which he places the driving levers, the motion of the feet of the rider is more or less perpendicular or horizontal.—Patent completed.

835 E. A. INGLEFIELD, Grove End-road, St. John's-wood. *Hydrostatic steering apparatus.* Dated March 19, 1869.

This consists in constructing and connecting a cylinder with the tiller in such a manner that for a single movement of the rudder several strokes of the piston of the cylinder are necessary, and thus the force resulting from the use of a moderately-sized cylinder during several strokes of its piston is accumulated so as to furnish the power required to move the rudder.—Patent completed.

836 J. THOMAS, Middlesborough-on-Tees, W. BACON, Newcastle-on-Tyne, and H. GROVES, Redcar. *Iron and steel.* Dated March 19, 1869

This consists in a new method or process for making refined iron, wrought iron, and also steel from melted metal run directly from the blast cupola or other furnace used for melting iron. The inventors refine the molten metal as it comes from the blast furnace, or the metal, if in pigs or casts crap, may be melted in a cupola, air furnace or any other furnace used for melting iron, and if the ground is practicable they prefer to build such furnace, which may be of any required capacity, at such a level that the metal may run direct from the blast or melting furnace into the air or refining furnace by gravitation, such air or refining furnace being contiguous or near to the blast or melting furnace. The refining furnace has a high crown, and on the top of the crown the inventors form a well, with one or more holes leading through the crown into the furnace. They heat the furnace up to the necessary heat for melting iron and fluxes, and they first melt the ores or oxides of iron with earths, alkalies, salts, or any other material used for cleansing or improving iron. When the fluxes are properly melted the inventors run or pour the molten metal into the well on the top of the crown, and let it run into the furnace through the holes.—Patent completed.

837 F. W. FOX, Bristol. *Railway engines and carriages.* Dated March 19, 1869.

The inventor connects the contiguous ends of the framework of the engines or carriages, or engine and carriages, combined by means of springs or elastic rings inserted in both or one of the outer frames at each side thereof. In the centre line of the engine and carriages, midway between the side connections, he passes a bolt or bolts through the two frames in such a manner that they can freely turn laterally upon such bolt or bolts, while the two frames, by this lateral connection, form practically one, admitting of no other relative motion beyond the lateral motion round the connecting bolt.—Patent completed.

838 A. ALBINI, Genoa. *Repeating firearms.* Dated March 19, 1869.

The inventor mounts the charge chamber on a tubular

axis fixed to an arm, which, when the cylinder is in position for firing, lies between the fore end of the cylinder and the back of the fore part of the frame. The lower end of the arm is jointed to the lower part of the frame at the side of the latter, so as to admit of the arm and cylinder being turned or swung out of the frame, in a vertical plane, at right angles to the axis of the barrel. In the tubular axis the inventor fits a rod, which carries the extractor and effects the locking and unlocking of the cylinder. This rod, which may be called the extractor rod, has a thumb plate or handle on its fore end, by means of which it can be slidden backwards and forwards within the tubular axis. A hole, of a diameter corresponding to that of the fore end of the extractor rod, is drilled in the fore part of the frame in a line with the axis of the cylinder, and communicates with a lateral slot cut in the frame, so as to allow the extractor rod to pass into and out of the hole, when the charge cylinder is turned on its hinge, that portion of the rod which comes opposite the slot when the rod is in its most forward position being cut away or reduced in diameter so as to allow the rod to pass through the slot.—Patent completed.

839 C. G. Bonehill, Birmingham. *Breech-loaders.* Dated March 19, 1869.

This relates to those kinds of breech-loading firearms in which the breech is opened for charging and closed for discharging by means of a block hinged to the side of the breech shoe. The invention consists in the arrangement or combination of parts for effecting the bolting down of the closing block by the fall of the hammer to discharge the gun. In the tail pin of the breech shoe of the gun is a sliding bolt pressed inwards or backwards by a coiled spring, so that its outer end lies flush with the said tail pin. The rear face of the closing block is furnished with a hole into which the said bolt can be shot. Projecting vertically from the bolt and working in a longitudinal slot in the tang of the tail pin is an arm, which arm carries at top a slide working upon the said tang. This slide covers the slot in which the vertical arm of the bolt works. On one side of the slide is an inclined projection. The hammer of the gun is provided with a shoulder, which, when the hammer falls to act upon the striker in the block, strikes against the projection described on the slide of the bolt. The bolt is thereby projected with the breech or closing block, and the latter bolted down firmly for discharge before the said hammer acts upon the striker.—Patent abandoned.

840 J. Jack, Liverpool. *Propelling vessels.* Dated March 19, 1869.

The inventor constructs that part of the ship immediately forward of the screw propeller of a form tapering towards the screw. By so doing a free entrance for water is provided, and to close in the tapered portion of the strip and the opening in which the propeller works the inventor employs a single or double slide or shutter operated from the deck. When the ship is under steam the slide or shutter is raised, and when under sail it is lowered.—Patent completed.

841 E. T. Hughes, Chancery-lane. *Scales.* (A communication.) Dated March 19, 1869.

This consists in combining parallel bars and vertical supporting rods for the table within a case the sides of which form the bearings of the parallel rods.—Patent abandoned.

842 S. Fox, Deepcar, near Sheffield. *Permanent way.* Dated March 19, 1869.

The inventor supports the ends of the rails where they are joined or connected to one another by a portion of rail placed beneath them, the two ends of such length of rail being hammered or flattened out so that they may rest upon the two sleepers between which the joint or connection of the rail occurs, and pass under the chairs which support the rail, and in order that the spikes which fasten the chairs to the sleepers may pass through the flattened out end portions of the rail.—Patent abandoned.

843 A. V. Newton, Chancery-lane. *Sewing machines.* (A communication.) Dated March 19, 1869.

The object is to provide an improved motive power for light running machines, and more particularly for sewing machines. The device is equally applicable to any of the known machines for sewing, giving the requisite motion and requiring only to be occasionally wound up, when it will furnish sufficient power to run the machine a certain length of time without further attention. The motive power mechanism consists of a series of gear wheels operated by means of springs, so arranged that the power exerted upon the machine to be driven will be uniform.—Patent completed.

844 W. R. Lake, Southampton-buildings. *Overshoes.* (A communication.) Dated March 19, 1869.

The construction of the improved shoe is peculiar so far as the upper is concerned. The sole and foxing are made in the manner commonly practised, and are secured to the cloth and vamp in the well understood way. The cloth which forms the upper is coated with india-rubber, which has been dissolved by any of the well known solvents. This thin solution is applied to the cloth by means of a knife in the manner in which rubber fabrics are usually coated by gum in solution.—Patent completed.

845 C. E. Brooman, Fleet-street. *Burning petroleum.* (A communication.) Dated March 19, 1869.

This consists in means for employing for heating purposes lighting apparatus, especially those fed by petroleum. The type apparatus consists of a long cylinder of iron or other material, having at its top a disc pierced with holes, in which the matters to be heated are placed. In the lower part of the cylinder the lamp is placed, and the products of combustion are carried off by a chimney of relatively small diameter, maintained by screws in the centre of the cylinder. Air is admitted by holes formed in the lower part of the apparatus. A spring coiled round a supporting rod tends to produce an improved movement of the support, and forces the case of the burner to press against the bottom of the chimney. A regulator and eyelet hole are provided. The above apparatus may be modified to serve for a great variety of purposes. More than one burner and chimney may be used when necessary.—Patent abandoned.

846 S. R. Wybrants, Dundee. *Textile fabrics.* Dated March 19, 1869.

This consists essentially in employing previously used materials, such as ropes of jute, hemp, flax, tow, cotton, wool, coir or manilla, or other material, for the manufacture of all kinds of bagging, sacking, coarse sheeting, and similar articles, for which rove yarns or heavy spun yarns have hitherto been or may be employed. The ropes may or may not be unstranded or broken up, and may be used as weft or warp without passing them over or through teasing or carding or roving machinery, but in some cases it may be advantageous to partly or wholly unstrand them for weaving, and the separate or combined strands may be reeled, warped, or formed into cops ready for weaving, and manufactured into cloth or other textile fabrics.—Patent completed.

847 J. Hamilton and R. Paterson, Glasgow. *Making aerated beverages.* Dated March 20, 1869.

The first part relates to apparatus for supplying carbonic acid gas to casks or other vessels containing beer or similar fermentable beverages, and, second, to collapsable vessels of a peculiar construction, for containing fermentable or aerated beverages.—Patent completed.

848 F. D. Nuttall, St. Helens, Lancaster. *Reverberatory furnaces.* Dated March 20, 1869.

This consists in constructing reverberatory furnaces with a combination of, first, a thin partition or wall formed at the back of the fuel chamber, so that there is left between the partition and the fire bridge an opening or passage, for the regulated admission of air upwards therethrough to commingle with the fuel gases and thereby promote combustion, and, second, an opening at the side or openings at both sides of the furnace, at or near the end or ends of the fire bridge, so that any deposit in or stoppage of the above-mentioned air passage may be easily reached and removed. The opening or openings is or are closed when the furnace is at work.—Patent completed.

849 J. D. Morrison, Grange-road, Edinburgh. *Heating and ventilating.* Dated March 20, 1869.

The grate, which is semi-circular in appearance between its pillars, and round from front to back, is composed of eleven principal parts, namely, a base, a channel chamber back, an outer semi-circular chamber, a chamber dome-top, an inner semi-circular chamber, a circular fire-grating, an ashpan, a fluted semi-circular fire-brick back, a semi-circular row of tube ribs placed vertically, and four quadrant doors and door guides.—Patent completed.

850 H. Whitehouse, Tipton, and W. Probert, Oldbury. *Tuyeres for blast furnaces.* Dated March 20, 1869.

The inventors take a piece of wrought iron or other tubing of a length about three times that of the tuyere to be made, and at or near the middle of this tube they bend it into nearly a complete circle, the side circle part being in a plane at right angles to the straight portions of the tube. The two unbent portions of the tube are parallel or nearly parallel. They place the bent tube described in a properly formed mould, and cast iron or other metal thereupon in the form of a conical or other shaped tuyere.—Patent completed.

851 F. Holmes, Hatcham-road, Surrey. *Blind pulleys.* Dated March 20, 1869.

To a piece of indiarubber the inventor secures a pulley by means of a collar or socket which clasps the same, and through which a pin or rivet is passed. This pulley has one of the bearings of its axis in an upright piece forming one piece with the collar, or being otherwise securely attached thereto, the other bearing of the pulley axis being on a piece which is free to move on the pulley axis, and has a catch which is fastened by means of the projecting end of the pin, which passes through the collar and the indiarubber as above stated.—Patent abandoned.

852 W. L. Wrey, United Service Institution, Whitehall. *Toothed gearing.* Dated March 20, 1869.

The inventor uses one toothed wheel of any ordinary or suitable form or construction, and to gear therewith he constructs another wheel which has two rings or circular frames, between which he arranges a number of rotating rollers or moving bars of any suitable form corresponding with the teeth of the wheel. As the teeth of the wheel take into the rollers or bars the same move on their axis, and thus, the action of the teeth being on a yielding and not on a rigid body, friction is reduced to a minimum.—Patent abandoned.

853 J. V. Robinson, Dublin. *Photo-negatives and raised surfaces.* Dated March 20, 1869.

This relates to the production of negatives for photographic printing, which is effected in the following manner:—Upon a plate of glass or other transparent material, the inventor deposits or affixes a layer or stratum of suitable metal (preferably of silver) or metallic alloy, or it may be a preparation of aniline or other suitable matter, upon which metallic or other surface a drawing may be made with pen or pencil. The lines of the drawing or design are then removed by means of a graver etching needle or other suitable instrument, or the drawing or design may be at once etched in without the aid of the first pen or pencil if desired. A plate is thus obtained from which the metal is removed in the parts representing lines in the drawing or subject, so as to admit light through the plate at those parts, and obstructing it wherever the metal deposit remains, thus producing what the inventor terms an etched negative.—Patent abandoned.

854 F. E. Duckham, Millwall. *Governors for marine engines.* Dated March 20, 1869.

One arrangement of this invention consists of a plunger or piston working in a cylinder, one end of which is open to the external water through an aperture in the side of the vessel. This cylinder is suitably disposed near the point of propulsion, so that when the screw or paddle near which it is placed is immersed, the piston will be also submerged. The piston rod is geared in any suitable manner with the steam through the valve, which is operated to admit the steam directly by the pressure of the external water on the piston or plunger, so that on the governor emerging from the water (which, consequently, ceases to exert any pressure on the piston) the steam will be cut off, a counterbalance being employed for the purpose if required.—Patent abandoned.

855 J. Kay, Glasgow. *Wind instrument.* Dated March 20, 1869.

This consists in forming the outer part of the flanch or that part which is applied to the lips of a curved form, the convexity of the curve being outwards. Curves of various forms, or a combination of curves, may be used in the same mouthpiece.—Patent completed.

856 H. E. Newton, Chancery-lane. *Measuring liquids.* (A communication.) Dated March 20, 1869.

An oscillating water-way is employed, arranged centrally between a double-chambered measuring vessel and the discharge orifice of a pipe, through which the liquid flows into the meter, and in combination therewith certain mechanism controlled by the alternate rise and descent of floats, applied within the measuring chambers to cause the water-way to oscillate, and turn the inflowing stream from one measuring chamber into another. Both measuring chambers are provided with outlets and valves, and these latter are connected to suitable apparatus in such a manner as to alternately open and shut their outlets, so that during the supply of liquid to one measuring chamber the liquid in the opposite chamber will be allowed to escape from it.—Patent completed.

857 H. E. Newton, Chancery-lane. *Motive power engine* (A communication.) Dated March 20, 1869.

This consists in the employment of a steam engine and an atmospheric engine combined, and relates to a new manner of utilising the heat force created in a steam boiler. The steam engine consists of a cylinder piston, piston rod, steam inlet pipe with valve, and steam and steam exhaust pipe.—Patent completed.

858 W. H. Phillips, Nunhead. *Water-fire machinery.* Dated March 22, 1869.

This consists of a chamber or reservoir for containing a supply of water or other liquid which is introduced through suitable passages. The chamber or reservoir is provided with means or apparatus, by means of which the space above the water in the chamber is charged with air or gas at a sufficient pressure to discharge the water from the chamber through a suitable outlet when a tap or valve is open.—Patent completed.

859 W. R. Lake, Southampton-buildings. *Hay-tedding machinery.* (A communication.) Dated March 22, 1869.

This consists primarily in such an organisation of the mechanism of rotary tedders as shall impart or cause to be imparted to each set of forks or teeth (arranged in an open rotary frame) a motion in excess of their relative motion, which acceleration of movement being given to them as they come into contact with the hay adds to the effectiveness of the forks or teeth in tossing or operating it.—Patent completed.

860 J. Booth, Birmingham. *Book indexes.* Dated March 22, 1869.

Instead of making the index of a series of leaves situated at the front of the ledger, each leaf being provided with one or more letters of the alphabet as usual, the inventor makes the index in the form of a long flap of calico or other flexible material attached or hinged to the inner side of the end board of the cover of the ledger and near the outer edge thereof. The flexible flap is covered on its upper side with paper ruled into a series of vertical columns, each column being provided with one, two, or more letters of the alphabet. The index flap is nearly of the width of the ledger with which it is used, but its length is varied according to the size of the ledger and the arrangement of the name columns.—Patent abandoned.

861 J. Loader, Upper Clifton-street, Worship-square. *Injectors.* Dated March 22, 1869.

The inventor employs a strong vessel in which a steam chamber pipe or pipes are coiled or otherwise arranged, one end of which is connected with the dome or steam space of the boiler, whilst the other is provided with a suitable valve. This vessel is also provided with suitable connections and valves, one of which leads into such vessel from the hot well or other supply, whilst the other leads from such vessel into the boiler.—Patent abandoned.

862 G. Lauder and G. Cope, Liverpool. *Tobacco twister.* Dated March 22, 1869.

To a pair of adjustable grooved pulleys revolving in the same plane, and so formed that there is left between them a circular opening or passage, the inventor imparts a double motion, viz., one on their own axis and another round the axis of a revolving disc on which they are carried. The first of these motions serves to shape the tobacco and propel it through between them, and the second to give the desired twist. The tobacco is fed by hand to the grooved pulleys to form a twisted core only, or it may be fed with the covering leaves laid on.—Patent abandoned.

863 T. Carrodus, Keighley. *Self-coupler for railway engines.* Dated March 22, 1869.

This consists of a self-acting tumbler or drop catch, or latch applied to each end of such carriages, and of a catch bar or latch plate also applied to each end of the carriages side by side with the catch or latch, and so placed that the catch or latch on one carriage will take into the catch bar or latch plate on another carriage, when two carriages are brought together, thus effecting a double coupling or connecting of two carriages.—Patent abandoned.

864 W. G. Crossley, Cambridge. *Wheels.* Dated March 22, 1869.

This consists in forming the nave of two plates or discs and a collar or ferrule, to which the central axle is secured by rivets or otherwise. The spokes are formed of separate pieces of hoop iron or steel, the inner ends of each of the spokes are looped by turning or folding the ends of the metal strips over and riveting them together, or a loop of metal is attached to the ends of the strips by rivets or otherwise.—Patent completed.

865 W. Crossley and J. W. Swithenbank, Bradford. *Shuttles.* Dated March 22, 1869.

This consists in constructing the spring in a single lap and inserting it in a vertical position in relation to the shuttle, so as to act on the end of the pike, by which the inventors avoid cutting any recess on the under side, or the use of the pins to secure it, whereby shuttles are much strengthened, and any oil used to lubricate the pike where the spring acts on it is prevented from dropping on the warp when the shuttle is in use.—Patent abandoned.

866 E. G. Reuss, Sheffield. *Table cutlery.* Dated March 22, 1869.

This consists in driving the tang of the knife or other instrument through the haft or handle, and riveting it at the other end, but several alterations are rendered necessary by the difference in the material of which the handles are constructed.—Patent abandoned.

867 H. Vansittart, Richmond. *Screw propellers.* Dated March 22, 1869.

This consists in adapting to the face or forward edge of any ordinary screw propeller a metal plate or plates of suitable form, and bent to the required curve according to the lines of the vessel and the proposed speed. This curved or waved line piece is placed straight or diagonally across the diameter of the leading side of the blade.—Patent abandoned.

868 J. Combe and J. Barbour, Belfast. *Rotary motion.* Dated March 22, 1869.

The inventors adapt to the machine to be driven what is known as White's improvement on Hooke's gearing. When the pressure endwise on the shaft caused by the angular setting of the teeth would be an objection, half the length of each tooth may be angled in one direction and the other half in the opposite, so that the pressures in the opposite directions will neutralise each other. Or, instead of the teeth being made angled to their axes, they may be divided into two or more sets, planes, or steps, with a lead, that is, the teeth of one plane or step being in line with the spaces between the teeth of the adjacent planes or steps, as in Hooke's gearing.—Patent completed.

869 M. Tildesley, Willenhall. *Door bolts.* Dated March 22, 1869.

This consists in performing both operations of bending or turning up and finishing by means of suitable dies in a stamp or under a steam hammer. These dies may both be formed upon one stamp or hammer, or separate stamps or hammers may be employed for each die, or the dies may be employed in a hydraulic or other powerful press. —Patent abandoned.

870 E. Stacey, Princes-street, Cavendish-square, and J. Thomson, Arthur-street, Peckham. *Purifying gas.* Dated March 22, 1869.

The inventors allow the tar and ammoniacal liquor to pass with the gas through the condenser, which he constructs with a series of horizontal pipes through which the gas passes above the tar and ammoniacal liquor, the temperature of the pipes being gradually diminished from the entrance to the exit end of the condenser. The gas, as it passes through the pipe, is gradually cooled, and the napthaline is absorbed therefrom by the tar instead of condensing in the main and service pipes.—Patent abandoned.

871 M. Sigler, Paterson, New Jersey. *Stretching warps.* Dated March 22, 1869.

This consists in the use of a series of rollers, fitted in a swinging frame, applied to the loom so as to receive and hang in the warp with such a degree of weight as may be best adapted to the fabric to be woven, the swinging frame being provided with an adjustment, by which the weight upon the warp may be increased or diminished at the pleasure of the attendant.—Patent completed.

872 J. J. Hicks, Hatton Garden. *Glass stoppers.* Dated March 22, 1869.

The inventor forms a stopper of glass, earthenware, vulcanite, or other suitable material in any desired colour by blowing, moulding, or other well-known means, and he forms from the lower end of such stopper to a certain distance up the side thereof, any desired number of grooves or cuts. The neck of the bottle is lined with cork, as is now well understood.—Patent abandoned.

873 J. E. Emerson, Trenton, New Jersey. *Rocking chairs.* Dated March 22, 1869.

This consists chiefly in the application to the chair, between the seat and the supporting stand or legs, of a spring, which allows the seat and upper portion of the chair to rock or oscillate freely upon an axis or centre below the seat, but which, by its resistance to expansion and contraction, confirms the motion of the chair within proper limits in either direction.—Patent completed.

874 G. T. Bousfield, Brixton. *Felting cloths.* (A communication.) Dated March 22, 1869.

This consists in improvements in jiggering machines for continuously hardening and felting felt cloths. The invention consists, first, in the arrangement and combination of an intermittently moving horizontal felting cylinder, with an intermittently moving conductor or hardening cloth and a horizontal concave jiggering apparatus. Second, in improvements in jiggering machines, in which the material is fed upon a carrying cloth between a flat-surfaced jigger and a platten.—Patent completed.

875 A. Clark, Rathbone-place. *Mixing paints.* (A communication.) Dated March 22, 1869.

This consists, first, in combining with a pan, tub, or other suitable holding vessel, revolving horizontally on its support, a rubbing or mixing apparatus, which turns about its support within or over the pan, tub, or other holder, so that the united movements of the pan or holder and of the rubber or mixers will form or resemble a series of circular lines, that cut or cross each other after the manner of lathe work or engine turning, as it is termed. —Patent completed.

876 J. Nicol, Stirling. *Envelopes.* Dated March 23, 1869.

This consists in cutting the closing flap with a lateral security extension, which, when the flap is closed down, can be turned over upon the address side of the envelope, at the corner usually occupied by the postage stamp.—Patent abandoned.

877 R. Gregson, Wigan. *Furnace firebars.* Dated March 23, 1869.

This consists in making endless travelling firebars with their upper surface alternately plain, and with a curved notch. The inventor is thus enabled to bring the lower edge of the suspended bridge in such a furnace nearer to the surface of the firebars, and at the same time allow the clinkers to pass under the bridge in the notches or hollow parts of the surface of the firebars, and thus prevent the accumulation of clinkers in the front of the bridge.—Patent abandoned.

878 G. Blanche, Paris. *Pocket guard.* Dated March 23, 1869.

The inventor employs a ring or other analogous device with an opening cut therein, or a piece of wire or metal curved so that its two ends nearly meet, leaving a similar space or opening to allow a portion of the clothing, whether the interior of the pocket, the lining thereof, or any other part of the apparel, to be inserted within such opening, and by means of a screw or screws upon the ends, or acting upon them. He closes this aperture upon the folds of the dress portion of the pocket or other part of the apparel within the opening or vacant space between the ends of the curved wire or piece of metal.—Patent abandoned.

879 C. Longfield, Birmingham. *Cramps.* Dated March 23, 1869.

The cramp is constructed in the form or shape represented on the drawings annexed to the published specification, and is made of iron or other suitable material of sufficient strength.—Patent completed.

880 J. Macintosh, North Barrack, Regent's Park. *Boots and shoes.* Dated March 23, 1869.

The inventor makes a vertical cut down each side of the boot or shoe to the depth of about 5in., and introduces four or five fillets transversely across the opening between the leather and the lining.—Patent completed.

881 L. A. Israel, Crescent, Minories. *Sulphuric acid.* Dated March 23, 1869.

This consists in manufacturing sulphuric acid in a chamber by means of a rotary or disturbing motion in combination with water, and by such means absorbing the gases generated; also in concentrating sulphuric acid and acids generally by the means and application of superheated steam.—Patent completed.

882 C. de Bergue, Strand. *Punching holes.* Dated March 23, 1869.

This consists in a mode or modes of making holes in metal by punching, by so mechanically feeding, grinding, or controlling the work, or presenting it to the action of the punch or punches as to obtain a regular or other accurate pitch or distance between the holes when punched, and at the same time to ensure a proper determined distance of the holes from the edge or edges of the work.—Patent abandoned.

883 J. Fryer, Redcar. *Rotary cultivator.* Dated March 23, 1869.

This consists in constructing cultivators having a series of diggers or blades arranged on a shaft or axle in such manner that, by means of suitable pins projecting from the wheels carrying the machine, such wheels, one or both of them, may by their onward motion be made to drive the shaft or axle holding such diggers or blades at a velocity quicker than the revolution of the carrying wheels when in movement.—Patent abandoned.

884 J. H. Johnson, Lincoln's Inn-fields. *Artificial stone blocks.* (A communication.) Dated March 23, 1869.

This relates to improvements in the artificial stone blocks known as "Beton agglomire," and consists in facing those parts of such blocks as are most liable to become worn or injured when in use with cast iron or steel projecting plates, whereby the durability of such blocks is greatly increased.—Patent completed.

885 F. Rudrum, Norwich. *Velocipedes.* Dated March 23 1869.

The velocipede is provided with a (compound or double) hind wheel, the parts of which can, when desired, be caused to separate and slide apart on the axle so as to form two wheels; the inventor arranges forked levers and gearing between the seat and this compound double wheel. The parts of this wheel are drawn together by a rack or other suitable arrangement when required, and can be held together until it is desired to separate them. This shifting gearing is worked by the handle of the guiding wheel.—Patent abandoned.

886 J. Horsley, Cheltenham. *Protecting nitro-glycerine.* Dated March 23, 1869.

For the purpose of protecting nitro-glycerine the inventor uses freshly powdered common alum (aluminous sulphate of potash or ammonia) or Epsom salts (sulphate or magnesia) containing the full complement of water of crystallisation, that is, undried or unexsiccated. Either of these earthy salts will answer, but preference is given to the alum, which is reduced to an extremely fine powder, and after passing it through a brass wire sieve of from 90 to 100 or 120 holes per linear inch (the finer the better), the inventor takes (say) 16oz. of the powder, and incorporates therewith in an open dish 4 fluid ounces (equal to 5½oz. or nearly 6oz. by weight) of nitro-glycerine, stirring the ingredients well first with a bone or wooden spatula till the oil or nitro-glycerine is absorbed, and finishing the operation with the hand or other suitable means so as to get it thoroughly blended.—Patent completed.

887 F. de Bowens, Philadelphia. *Match splints.* Dated March 23, 1869.

This consists in cutting match sticks and other similar short sticks from blocks of wood secured to a large rotating wheel. Also in the shape of the cutting knives and the arrangement of the cuts, the operation of the mechanism for giving motion to the knives, and the mode of depositing the sticks in the dipping frames as they fall from the knives.—Patent completed.

888 M. F. Maury, Gloucester-place, Dorset-square. *Heating by electricity.* Dated March 24, 1869.

This consists of a chain or coil composed or made up of alternate obstructions and free conductors, arranged in any compact form and properly insulated, and in applying it the inventor proposes to use any kind of electricity which might be best adapted for the particular application of it.—Patent abandoned.

889 J. B. Fell, Spark-bridge, Lancashire. *Locomotives.* Dated March 24, 1869.

This consists of an arrangement or arrangements for putting pressure on the gripping wheels of centre-rail locomotives. The right and left-handed screw shaft passing through the compressing beams is arranged so that by its means and that of the volute springs interposed between the beams and the cradles, the pressure is put on the horizontal wheels. A worm wheel is used for turning the shaft, which is worked by a worm and shaft from the foot plate of the engine. Blocks are attached by pins or trunnions to the compression beams, the object of which is to allow those beams slightly to swivel and take an oblique position, and thus to follow any similar movement in the cradles when the engine is passing round sharp curves. In this manner, the additional strains to which the compression beams and screw shaft might be subjected from the above cause may be avoided.—Patent completed.

890 R. W. Page, South Molton-street, W. *Garden re engines.* Dated March 24, 1869.

The engine consists of a water cylinder surrounded by or in communication with an air chamber supported by a foot and base plate resting on the ground, water being admitted at the top of the cylinder and discharged therefrom at the bottom.—Patent completed.

891 W. Harrison, King Edward-street, E.C. *Head sunshade.* (A communication.) Dated March 24, 1869.

The improved shade is composed of a round or oval piece of textile or other suitable material, in the centre of which is formed a circular or oval opening of sufficient size to give passage to the body of the hat. The edge of this opening is surrounded by an elastic band or binding by the tension of which the shade is maintained in position on the hat, and from this band radiates a series of stretchers composed of whalebone, cane, steel, or other suitable flexible material.—Patent abandoned.

892 C. M'Dermott, Edge Hill, Liverpool. *Eyelets and paper fasteners.* Dated March 24, 1869.

This consists of three parts, which are denominated, first, the base; second, the prong; third, the plunger. The base is the foot or that part upon which the press is built. The prong is a round piece of steel riveted to the base and projecting upwards. The plunger is a piece of rounded metal about 6in. in length and ⅜in. in diameter, having a flattened head piece suitable to the application of pressure by the palm of the hand.—Patent abandoned.

893 F. J. Manceaux, Paris. *Firearms.* Dated March 24, 1869.

This relates to a previous patent granted to the same inventor dated March 30, 1867 (No. 962.) The present invention consists in fitting the barrels between plates which stretch across from one side to the other, and connected to side plates or straps by means of screws or otherwise. The side plates are carried on trunnions and are held in place by screw nuts. The trunnions enable the apparatus to be mounted upon a carriage so that it can be used in field operations. The rear ends of the side plates are of greater thickness, the thicker parts being slotted on the under side for the plates of the breech-closer to work in as hereafter described. These plates are centred upon pins, one of the ends of each of which has screw nuts on it. The pins are prevented working loose by means of tappets.—Patent completed.

894 V. Chemery, Sedan, France. *Damping and pressing cloth.* Dated March 24, 1869.

The apparatus is composed of two pipes or tubes, one placed within the other, a space being formed between them. The inner one is perforated with holes, preferably at the lower part, and is furnished with washers or distancing plates upon which the outer tube rests. The steam which passes through the perforations is distributed over the entire inner surface of the other tube.—Patent abandoned.

895 The abstract of this specification will appear in a future number.

896 W. E. Newton, Chancery-lane. *Working heavy guns* (A communication.) Dated March 24, 1869.

This consists in using an air cylinder in connection with the levers for upholding the gun, so that air, when in its natural density, may be compressed in the cylinder by the force of the recoil of the gun acting on a plunger or piston which moves in the cylinder, and by retaining this air while thus compressed the power developed by the recoil is stored up, and may be released at the will of the operator.—Patent completed.

897 A. Clayton, Southampton. *Firearms.* Dated March 24, 1869.

This consists, first, in an arrangement of the parts whereby the ordinary lock mechanism is dispensed with. The barrel of the gun is connected with the body by means of lumps, in which an axis or screw parallel to the axis of the barrel is supported and works, the opening of the breech being effected by turning aside the body from the barrel upon the said axis or screw. The nipple is fixed to receive the percussion cap on the side of the barrel, and a long spring, carrying at its free end the hammer, is fixed at its other end to the side of the barrel, the hammer on the free end of the spring pressing on the nipple. A curved lever is jointed to the side of the body, the lower end of the said lever constituting the trigger.—Patent abandoned.

898 T. Shakespear and G. Illston, Birmingham. *Sewing machines.* Dated March 24, 1869.

At or near the end of the principal shaft of the sewing machine the inventors fix a wheel, which receives a rotary motion from the said shaft. A vibrating arm or lever, working in a plane parallel to that in which the said wheel works, is geared to the said wheel by means of a connecting rod connected to the face of the wheel by a crank pin. The connecting rod and arm give motion to a rocking shaft working in the upright or frame supporting the feed plate of the machine. The other end of the rocking shaft carries another arm or lever, the upper end of which is geared to the shuttle carrier by means of a connecting rod jointed to the end of the said lever and to the said shuttle carrier. When the machine is worked, the wheel on the principal shaft communicates a reciprocating motion to the first-named vibrating arm or lever, which motion is transmitted by the rocking shaft to the other arm or lever, and through it and the connecting rod to the shuttle carrier.—Patent completed.

899 C. B. Parkinson, W. H. Heald, and A. and J. Metcalf, Preston. *Spinning mules.* Dated March 24, 1869.

The machine consists of the ordinary carriage chain and rope barrel. The chain, which in some instances instead of hooking on to the nut worked by the screw in the quadrant radius arm is passed over a pulley, down over another pulley (which in some instances is not required), over an eccentric, and the end secured on the eccentric. On the side of this eccentric is a pulley, on which is secured the end of the chain, which comes round and under to stud on to the side and near the bottom of the radius rail. On the upper part of this radius rail is fixed a lever, to the end of which is worked one end of a connecting rod, the other end of which is connected to the carriage.—Patent completed.

900 F. Baker, Kennington. *Locking signal levers.* Dated March 24, 1869.

The shafts or pivots on which the various hooks or catches, stops, and actuating cranks work are arranged in suitable diagonal frames or supports, placed at the same or nearly the same angle or inclination as the levers when pulled over.—Patent completed.

APPLICATIONS FOR LETTERS PATENT.

Dated October 5, 1869.

2880 C. Montagu, Cannon-street, City. An improvement in umbrellas, parasols, and sunshades.

2881 T. Atkinson, Hull. Improvements in machinery or apparatus for expressing oil, and for the manufacture of cake from the residue thereof.

2882 W. Horsfall, New York, U.S. Improvements in machinery for forging bolts, screws, and spikes.

2883 J. N. Batey, Landport, Hants. Improvements in hammers for sewing machines.

2884 J. Winter, Wardour-street, Soho, Middlesex. Improved apparatus for filling glass bottles and jars with soups, jellies, fruits, and other edibles, for the purpose of preserving them with the said apparatus, being also applicable for filling bottles with sauces, wines, spirits, beer, liqueurs, and other still and effervescing beverages; also machinery in combination with the above apparatus for corking or stoppering such said bottles and jars.

2885 F. Hazeldine, Lant-street, Borough, Surrey. An improved corkscrew adapted for gaseous and aerated liquids.

2886 W. Morris, Triangle, Halifax, and J. Teal, Sowerby, Halifax. Improvements in machinery to be employed for combing wool.

2887 L. Byrne, Birmingham. A new or improved construction of pump for domestic, horticultural, and other useful purposes.

2888 H. Howard-Keeling, King and Queen Ironworks, Rotherhithe, Surrey. Improvements in manufacturing bars or links of wrought iron or other metal used in the construction of suspension or girder bridges, and for other purposes.

2889 T. W. Bunning, Newcastle-upon-Tyne, and W. Cochrane, Oakfield House, Coxlodge, Northumberland. Improvements in apparatus used in getting coal, stone, and other minerals.

2890 J Kircher, Cannstadt, Wurtemberg, and E. Ebner, Stuttgard, Wurtemberg. An improved black printing ink capable of being removed from paper.

2891 J. Kircher, Cannstadt, Wurtemberg, and E. Ebner, Stuttgard, Wurtemberg. An improved mode of removing print from paper.

2892 E. Smethurst, Stockport, Cheshire. Improvements in funnels or funnel measures for the measuring and pouring of liquids into vessels.

2893 T. Adams, Laurel-grove, Penge, Surrey. Improvements in the slide valves and pistons of steam and other engines.

2894 J. Clayton, Preston, Lancashire. Improvements in the construction of boilers for generating steam.

2895 W. Richardson, Oldham. Improvements in machinery for burring or cleaning wool, cotton, and other fibrous materials.

2896 C. E. Spooner, Bron-y-Garth, Port Madoc, Carnarvonshire. Improved machinery for bending rails or bars for railways or other purposes.

Dated October 6, 1869.

2897 S. Farron, Ashton-under-Lyne. Improvements in the construction of cocks or taps.

2898 E. Wigzell and J. Pollit, Sowerby Bridge, near Halifax. Improvements in metallic pistons for steam engines, and in the manufacture thereof.

2899 W. A. Whitty, Strand. An improved advertising medium.

2900 J. W. Powell, East lane, Bermondsey, Surrey. An improved valve cock.

2901 B. Hunt, Serle-street, Lincoln's Inn. Improvements in the decoration or ornamentation of metals.

2902 H. and A. Holmes, Derby. Improvements in axletrees for carriages and other vehicles.

2903 W. R. Lake, Southampton-buildings, Chancery-lane. Improvements in the permanent way of railways.

2904 E. Russ and H. and E. Hammond, Winchester, Hants. Improvements in breech-loading firearms.

2905 T. F. Newell, Cloak-lane, City. Improvements in rag engines for the preparation of paper pulp.

2906 E. A. Pontifex, Shoe-lane, City. Improvements in refrigerators for cooling worts and other liquids.

2907 E. Tyer, Old Jewry Chambers, City. Improvements in electro-magnetic telegraphic apparatus for train signalling on railways, part of which apparatus may be employed for other useful purposes.

2908 W. H. Horsley, Waltham-street, Hull. Improvements in washing machines.

2909 E. B. de Leon, Boulevart Bonne Nouvelle, Paris. Printing without heat upon wood used for cases, bars, or heads of casks and packages of all kinds, any mark, countermark, inscription or drawing in relief, in sunken or in surface impression, in one or several varied colours as well as in gold and silver, for trade purposes generally, and particularly for the wine and spirit trade, in lieu and place of the marking obtained by hot brand and open vignettes.

2910 W. E. Newton, Chancery-lane. Improvements in the permanent way of railways and tramways.

2911 J. F. M. Pollock, Leopold-street, New Leeds, Leeds. Improvements in machinery for making bricks and other similar articles.

Dated October 7, 1869.

2912 J. M'Kenzie, Glasgow. An improved method of jointing, fastening, and securing rails in railway chairs.

2913 A. Coleman, St. Mary-at-Hill, Middlesex, and W. Coleman, Whitefield, Heaton Norris, Lancashire. Improvements in latches or locks applicable especially to railway carriage doors.

2914 J. C. Ramsden, Bradford, Yorkshire. Improvements in looms for weaving.

2915 H. Schildberg, Westminster Chambers, Victoria-street, Middlesex. Improved signalling apparatus for use in private or public buildings.

2916 W. E. Newton, Chancery-lane. An improved form of wheel for propelling ships, and applicable also to pumps for raising or forcing water.

2917 W. P. Gregg, Boston, Massachusetts, U.S.A. Invention having reference to parlour or roller skates.

Dated October 8, 1869.

2918 R. Chapman, Shrewsbury, Salop. Improvements in the construction and mode of fastening railway fish-plates and chairs.

2919 D. Parrish, Threadneedle-street, City. Improvements in axle boxes.

2920 J. Hilton, Albert-road Ironworks, Farnworth, Lancashire. Improvements in casting socket and flanged pipes.

2921 J. Duckworth, T. Hindle, and G. B. Jerram, Liverpool. Improvements in the construction of concrete and cement buildings, structures, and articles, and in apparatus to be employed therein.

2922 G. W. Hawksley and M. Wild, Brightside Boiler Works, Sheffield. Improvements in the construction of steam boilers.

2923 W. R. Lake, Southampton-buildings, Chancery-lane. Improvements in pedals and damping apparatus for pianofortes and other similar instruments.

2924 T. Rice, Bath-street, City-road, Middlesex. Improvements in fixing door knobs or handles on to the spindles of door locks.

2925 A. Etienne, Charlotte-street, Fitzroy-square, Middlesex. Improvements in the construction of carriages, vehicles, and velocipedes.

2926 O. C. Evans, Upper Grange-road, Bermondsey, Surrey. Improvements in wheels for vehicles and other purposes.

2927 N. Wilson, High Holborn, and W. Campion, Nottingham. Improvements in sewing machines.

2928 H. Wainwright, Rue Gaillon, Paris. Improved apparatus for distilling and producing fresh potable water.

2929 J. Fearson, Birmingham. Improvements in water tuyeres for forges and furnaces, and in apparatus connected therewith.

2930 J. Wallace, College-square, East Belfast. The distilling of alcoholic liquors.

2931 W. J. Jones, King-street, Cheapside, City. Improvements in the construction of hot water boilers.

Dated October 9, 1869.

2932 C. E. Brooman, Fleet-street, City, patent agent. Improvements in liquid meters or apparatus for measuring the flow of liquids. (A communication.)

2933 J. Chandler, Cottage-grove, Mile End-road, Middlesex. Improvements in apparatus for drawing and preventing waste of water from pipes, mains, cisterns, or other sources, for domestic or other purposes, also for waterclosets, &c.

2934 J. More, Lee, Kent. Improvements in the preparation of oils for painting or other purposes.

2935 R. L. Hickes, Liverpool-street, Old Broad-street, Middlesex. Improvements in the modes or methods of applying electricity to obtain motive power, and for other useful purposes.

2936 W. Kelsey, Cannon-street, City. Improvements in driving drums or pulleys and railway wheels.

2937 D. Sowden, R. C. Stephenson, and J. Myers, Bradford, Yorkshire. Improvements in looms for weaving.

2938 B. Baugh and B. Walters, Birmingham. Improvements in ornamenting bricks, building blocks, and roofing and other tiles.

2939 J. H. Johnson, Lincoln's Inn-fields. Improvements in nail-making machines.

2940 H. Reid, Herne Bay, Kent. Improvements in the treatment and preparation of clays for the manufacture of Portland and other cements.

2941 W. N. Hartley, Litchfield, Staffordshire. Improvements in whitening or bleaching yarns, fabrics, and fibrous substances.

2942 A. H. Brandon, Rue Gaillon, Paris. Improved means of locomotion or summer skate.

2943 E. H. C. Monckton, Oriental Bank Corporation, Threadneedle-street, City. Improvements in railways, in motive and locomotive power.

2944 E. H. C. Monckton, Oriental Bank Corporation, Threadneedle-street, City. Improvements in guns, cartridges, and projectiles.

2945 A. M. Clark, Chancery-lane. Improvements in high and low water level indicators for steam boilers.

2946 W. C. May, Sanders'-terrace, Chobham-road, Stratford, Essex. Improved non-oleaginous printing inks and non-oleaginous printing varnishes.

2947 C. Wyndham, Southover, near Lewes, Sussex. Improvements in wheeled vehicles commonly known as velocipedes.

2948 J. H. W. Biggs, Manchester. Improvements in machinery for joining warp ends.

2949 A. Welch, Southall, Middlesex. Improvements in cattle trucks.

Dated October 11, 1869.

2950 A. C. Kirk, Glasgow. Improvements in treating mineral oils.

2951 G. A. Middlemiss, Sunderland, Durham. An improvement in withdrawing water or other fluids in as pure a condition as possible from wells, cisterns, and other places where the water or other fluid is mixed with foreign matter; also to prevent the choking up of the pumps and other instruments usually used for drawing off water and other fluids.

2952 J. Huggett, Terminus-road, Eastbourne, Sussex, and J. A. Huggett, Union-grove, Clapham, Surrey. Improvements in the manufacture of nails, and in apparatus employed in such manufacture.

2953 E. A. Cowper, Great George-street, Westminster. Improvements in treating cast iron for the production of wrought iron and steel therefrom, and in apparatus employed for that purpose.

2954 A. V. Newton, Chancery-lane. An improved mode of, and apparatus for, manufacturing paper hangings.

2955 T. Greenwood, Leeds, and J. Keats, Leek, Staffordshire. Improvements in the manufacture of boots and shoes, and in machinery to be used therein.

2956 W. R. Lake, Southampton-buildings, Chancery-lane. Improvements in the construction of land cultivators.

2957 W. R. Lake, Southampton-buildings, Chancery-lane. Improvements in the permanent way of railways.

LIST OF SEALED PATENTS.

Sealed October 9, 1869.

1132 R. E. and C. Marshall
1133 W. Gillespie
1137 F. Erskine
1141 E. Dowling
1145 W. H. and T. Hacking and J. Chambers
1152 J. H. Johnson
1163 E. Cooper
1169 J. H. Johnson
1170 W. J. Cowlman and A. Doe
1171 A. K. Rider

Notice.—Having received communications from persons residing in the country to the effect that difficulties are occasionally experienced by them in obtaining copies of printed specification from the Patent Office, in consequence of the varying nature of the postage thereon, our readers are informed that upon receipt from them of particulars of the specifications they require, together with a remittance for the cost and approximate postage thereof, we shall be happy to procure and forward such specifications free of all further charge. Sums under Five Shillings may be remitted in postage stamps, for sums above that amount a Post Office Money Order should be sent, payable to Robertson, Brooman, and Co., Patent Department, 166, Fleet-street, London, E.C., to whom all communications upon the subject should be addressed.

THE

MECHANICS' MAGAZINE.

LONDON: FRIDAY, OCTOBER 22, 1869.

THE GOLD AND SILVER COINS OF ENGLAND.

AS there still appears to be much misconception existing in respect to the coinage question, and comparatively few persons are acquainted with the precise system upon which our metallic currency is based, we purpose furnishing a few facts which may help to elucidate the subject. From the tenor of many of the letters which have recently appeared in the journals of the day in reference to the gold coinage it might be and indeed has been inferred that the Mint is in the habit of receiving gold from all and sundry who choose to take it there, and of giving in exchange for it sovereigns, weight for weight, and free of all cost to the importers. This arrangement is really in accordance with the coinage laws of the United Kingdom, but in practice it is seldom or never carried out. Nearly forty years have elapsed since the Mint has dealt in this way with private importers of bullion, and the last of these were the Messrs. Rothschild. Successful golddiggers and others on their arrival in this country laden with nuggets and auriferous dust find their way to bullion dealers, who purchase the precious material at an estimated price, refine it, and sell it to the Bank of England. The market price of standard gold is £3 17s. 9d. per oz., and what is termed the Mint price £3 17s. 10½d. per oz. The Bank therefore makes an apparent profit of 1½d. per oz. upon all the gold which it sends to the Mint for conversion into coin. It further enjoys the privilege of sending into that place as much as it pleases and whenever it likes.

The Mint is thus, so far as gold is concerned, a manufacturing branch of the Bank of England, and its presses are active or idle as the latter may desire. The Bank pays nothing whatever to the Mint for the use of its machinery or otherwise, and the expense of maintaining it is borne wholly by the State. The Bank thus represents all the sellers of gold, and enjoys the advantages which the law theoretically grants to them.

It is not necessary to explain the precise method pursued by the Bank and the Mint in the transfer of the metal and coin from one to the other, but the transactions are always on a large scale. It is seldom indeed that the Mint is required to coin less than a million of sovereigns off hand, and generally five or six millions are wanted.* The form in which the material is sent into the Mint, almost invariably, is that of ingots. These weigh each 200oz., and are 8in. long, 3in. broad, and 1in. thick, the value of such a wedge being nearly £800. One hundred of these are technically termed "an importation." After being duly assayed and reported upon as to fineness, the ingots are cast into bars for coinage. These latter are rolled, cut, annealed, blanched, and otherwise dealt with until they are converted into sovereigns or half sovereigns, as may be desired by the Bank.

We now arrive at a stage in the history of the sovereign which is highly interesting. The law demands that, theoretically at least, the weight of each coin shall be precisely 123·2744 grains. Practically this is an impossibility. The most perfect machinery in the world cannot be made to accomplish the desideratum unless at a cost so great as to be entirely inadmissible. Pieces of gold rolled and cut with mathematical precision, and so that no micrometer gauge, however delicate, would detect differences of size, will yet be found to differ in weight when placed in the fine balances of the Mint. The truth is, that uniform density or homogeneity in the metal cannot be attained to, and without uniformity the weight of individual coins must vary. The law recognises the fact, and propounds a remedy for the evil. The remedy is a legal allowance above and below the true standard. This amounts to 12 grains on each pound weight (troy) of sovereigns or half sovereigns coined, whether over or under the standard. The Mint endeavours to balance the difference on either side, and, on large quantities, to give standard results. Thus, a thousand sovereigns weighed collectively would be found to be of the true standard weight which the law demands, although not more than one hundred tested individually would be found to weigh precisely 123·2744 grains. The remedy legally allowed on each sovereign is ·256 grains, say a quarter of a grain, or one halfpenny worth of standard gold. The legal maximum weight, therefore, at which a sovereign may pass from the Mint for circulation is 123·531 grains, and the legal minimum weight 123·017 grains. For the half sovereign the legal maximum weight is 61·765 grains, the legal minimum weight 61·508 grains, and the remedy ·128 grains. Out of these limits it is not possible for any gold coin to escape, being returned to the Mint crucibles, and it is not too much to say that since automatic weighing was introduced in 1851 into the Mint, not a single "too heavy" or "too light" sovereign or half sovereign has left the Mint gates. Before following a batch of carefully sized sovereigns out of the Mint, let us examine what Mr. Lowe's improved (?) system would do with the coinage within its walls. That gentleman proposes to reduce the theoretical weight of each sovereign by 1 grain and therefore to make it 122·2744 grains, or twopence less in actual value than at present. He cannot interfere with the "remedy." That is already low enough for all practical purposes, and high enough for the public security.

The allowance for fallibility of workmanship, as it is termed in legal parlance, of 12 grains on the 1lb. troy will still, therefore, remain intact; but since 40lbs. weight of gold by the Lowe proposition will be cut into 1,884, instead of 1,869 sovereigns, as at present, the 12 grains of allowance must be equally distributed over the larger number of pieces. Individually, therefore, the remedy will be slightly less, though collectively the same. Thus the practical difficulty and cost of coining will be increased, for every diminution of the remedy, however trifling, ensures an increase of the percentage of rejected coins to be returned to the furnace. Of the diminished value of the coins when issued, and the inconveniences which would arise from that circumstance, it is not necessary again to speak, except to say that every coin would be actually twopence less in value than those now issued from the Mint, and that it would be taken for what it is worth and no more. In order to the complete understanding of Mint operations, so far as the weights of gold coins are concerned, we shall here furnish a table, which from foregoing explanations will be readily comprehended:—

MINT WEIGHTS OF GOLD COINS.

Denomination of Coin.	Standard weight.	Legal remedy.	Legal maximum weight.	Legal minimum weight.	Weight at which coins cease to be a legal tender.
	gr. prts.	gr. prts.	gr. prts.	gr. prts.	gr. prts.
Sovereign...	123·274	0·256	123·531	123·0·7	122·500
½-Sovereign	61·637	0·128	61·765	61·508	61·125

Under the Chancellor of the Exchequer's proposed arrangement, these figures would be reduced in the proportion of one grain in the sovereign and one half grain in the half sovereign, and both coins would therefore be issued from the Mint at a weight sensibly below that at which they now cease to be a legal tender. In addition to this most serious consideration, there must be taken into account the fact that the process of deterioration commences with the gold currency as soon as it passes from the Bank of England. When a sovereign emerges from that palace and mixes freely with the people, degeneration surely follows the act. Abrasion and attrition commence their baleful work at once. If the sovereign does not lose in authority, it quickly loses in weight. The eye of the law is upon the traveller, and bankers' balances reveal the growing weakness of his constitution. At a certain stage of declension, the axe falls, his circulation ceases, and the victim is relegated to the crucible! The fell moment legally arrives when the weight of the piece is less by ·774 or (say) three-quarters of a grain than the theoretical standard. Such a coin would, at this point, be worth a halfpenny more than the Lowe sovereign when newly minted, and twopence more than a worn-out specimen of that coin. In short, the latter would begin life as mere tokens of value, and end it as they began. To all intents and purposes the gold coinage would thus be placed on a footing of equality with the silver coinage, of which we are desirous also of saying a few words. As at present organised, the Mint purchases silver for itself in the market, though generally at the instigation of the Bank. The market price of standard silver* varies from 5s. 0½d. to 5s. 2d. per ounce. The law says that 1lb. troy shall be coined into 66 shillings, and other denominations in proportion. The Mint thus makes a large profit or seignorage on the coinage of silver moneys. Thus, whilst, as at this moment, £1,000 in gold, whether in the form of coin or bars, is worth intrinsically £1,000, £1,000 in silver coins newly struck is only worth £925 in silver bars.

This large seignorage pays all the Mint expense of coining silver, and enables it to undertake the obligation of giving the Bank new silver coins for worn and light ones. (It would be well if the Mint performed this last operation more completely, for the silver coinage generally is in a very bad state.) By reducing the weight of the sovereign, the relative value of the shilling and other silver coins will be lessened too, and this is another argument against alteration. Upon this branch of the coinage question it is probable that, at some future time, a few reflections may be submitted, but, in this instance, out of consideration to space and other circumstances, we shall simply furnish a tabular view of the

MINT WEIGHTS OF BRITISH SILVER COINS.

Denomination of Coin.	Standard weight.	Legal remedy.	Legal maximum weight.	Legal minimum weight.	When not a legal Tender.
	gr. prts.	gr. prts.	gr. prts.	gr. prts.	
Florin	174·548	0·727	175·272	173·818	If clipped or defaced wilfully, or the Mint mark invisible.
Shilling ...	87·272	0·363	87·636	86·909	
Sixpence ...	43·636	0·18	43·818	43·454	
Threepence	21·818	0·090	21·909	21·727	

From the tabular statement, crowns, half-crowns, and fourpences are omitted because they are never coined now, and are, in fact, dying out.

THE WOOLWICH MUZZLE-LOADING GUN.

THE most recent novelty at Woolwich in the way of gun construction is the substitution of a wrought-iron breech coil and trunnion coil for the single massive forging hitherto used in the heavy guns of the Fraser construction up to 11in. calibre. The first piece of ordnance made upon this double coil system is a 12-inch Woolwich muzzle-loading rifled gun. The piece was tried this day week at Shoeburyness, upon which occasion

* The productive power of the Mint is equal to the creation of one million of coins of any denomination per week

* Standard silver is composed of 222dwts. fine silver and 18dwts. copper = 240dwts.

twenty rounds of 600lb. shot were fired from it with 67lb. charges of large grain rifle powder. This is the first instalment of a series of 200 rounds for testing its accuracy, range, and endurance. The gun is 14ft. 2in. in length; it weighs 25 tons, and is vented with hardened copper. It was mounted on a wrought-iron carriage and dwarf platform, running with flat-soled trucks with only a front flange upon C-racers, and was traversed with facility by Cunningham's chain gear worked by four men. It was also fitted with Colonel Clerk's hydraulic buffer, which acted admirably in checking the recoil. The buffer is 8in. in diameter, and about 6ft. in length; the diameter of the piston rod being 2 in. The quantity of water in it was 12 gallons. The shot were of cast-iron solid, of the same dimensions and weight as the service Palliser shot for this weapon. The first five rounds fired were at two degrees elevation, the times of flight of projectiles being respectively in second 3, 3·1, 3, 3, 3; the recoils 6ft., 6ft. ¼in., 6ft., 5ft. 11in., 5ft. 10¼in. The second five rounds were at four degrees; flights, 5·1, 5·3, 5·2, 5·1, 5·2 seconds; recoils, 5ft. 9in., 5ft. 9in., 5ft. 9in., 5ft. 9in., 5ft. 8¾in. The third five rounds were at six degrees; flights, 7·4, 7·6, 7·8, 7·6, 7·9 seconds; recoils, 5ft. 7in., 5ft. 8in., 5ft. 8in., 5ft. 8in., 5ft. 8in. The fourth five rounds were at eight degrees; times of flight respectively 10, 10, 10, 10·1, 10 seconds; recoils, 5ft. 7in., 5ft. 7in., 5ft. 8in., 5ft. 6in., 5ft. 7in. The ranges were at two degrees about 1,100 yards, at four degrees 1,830, at six degrees 2,650, and at eight degrees 3,450 yards. The line of fire was very good, the extreme deviations from the pegs being at the six degrees practice from 4yds. left to 4yds. right, at the eight degrees practice from 1yd. left to 4yds. right. The experiments were conducted by Captain Alderson, R.A., assistant superintendent, under the direction of Colonel Elwyn, R.A., the commandant.

THE BRITISH INDIAN SUBMARINE CABLE.

WE have to record the successful completion and storage on board the "Great Eastern" of the cable for the above line which is to be laid between Bombay and Suez. According to present arrangements the "Great Eastern" will leave Sheerness to-morrow (Saturday) with this work, which there is every reason to hope will be successfully laid. Having so recently given the particulars of the British Indian submarine cable,* it will be unnecessary here to repeat ourselves. We will merely mention that the work to be carried out consists of two cables—one of 1,550 knots, from Suez to Aden, and the other of 2,050 knots, from Aden to Bombay. This gives a total length of 3,600 nautical miles, and constitutes the longest submarine cable ever manufactured. To celebrate the successful manufacture of this cable, and to wish the important enterprise, and those who will have the practical carrying out of the work, good speed, the chairman, directors, and friends of the Telegraph Construction and Maintenance Company dined at the Albion Tavern on Wednesday evening. The chair was occupied by Sir Daniel Gooch, Bart., and among those present were—Lord Houghton, Lord W. Hay, the Right Hon. W. Massey, Captain S. Osborn, C.B., Mr. J. Pender, Sir J. Anderson, Sir C. Bright, Sir J. Whitworth, Hon. A. Cochrane, Lord S. Cecil, Mr. R. W. Crawford, M.P., Mr. G. Elliot, M.P., Admiral Hall, Mr. E. J. Reed, CB, Dr. W. H. Russell, Captain Halpin, Mr Willoughby Smith, Mr. W. T. Henley, Mr. Shuter, Mr. G. Sayward, Mr. J. Chatterton, Mr. H. Clifford, &c. After the usual loyal and patriotic toasts, Lord William Hay proposed "The Prosperity of our Indian Empire and of our Eastern Colonies," coupled with the names of Mr. Massey and Mr. Verdon, and, in a brief speech, referred to the immense importance of direct telegraphic communication with India. Mr. Massey said that he looked forward with confidence to the completion of the cable between Egypt and India, and he was pleased to be able to announce that on that day arrangements had been completed for the extension of the cable to the principal Chinese ports, by means of Ceylon and Singapore, and thence also to Australia. Mr. Verdon, in the name of the Australian colonies, also acknowledged the toast, and especially referred to the great want of telegraphic communication with Europe that is now felt by all the people of Australasia. "The British Indian Submarine Telegraph Company" was proposed by the Chairman, who said he hoped the cable between Bombay and Suez would be laid not later than the month of February next, while it was expected that the cable between Falmouth and Malta would be laid in the following June, thus completing our telegraphic communication with India. Mr. Pender, with whose name the toast was associated, briefly acknowledged it, and proposed the toast of "Prosperity to the Telegraph Construction and Maintenance Company," connected with the name of Sir D. Gooch, the chairman. The compliment was suitably replied to, and some other toasts of a personal and friendly character, including those of Captain S. Osborn, the managing director, and Captain Halpin, of the "Great Eastern," brought the proceedings of a very pleasant evening to a close. We trust the day is not far off when by means of the line between Bombay and Suez, and of another line between Falmouth and Malta, our telegraphic connections with India will be rapid and complete. The accomplishment of such a scheme cannot but be highly advantageous to the commerce and industry both of England and India.

The further extensions eastward of the cable referred to above is naturally consequent upon the establishment of direct telegraphic communication with India by the formation of the Falmouth, Gibraltar, and Malta, Anglo-Mediterranean, and British Indian Companies, whose cables are expected to be open for traffic next May. For this purpose a company has been formed, with a proposed capital of £460,000, in 46,000 shares of £10 each. By this company a cable will be laid from Galle to Singapore, touching at Penang and Malacca, as a first instalment towards connecting Australia and China with the Indian and European systems. Negociations are in progress, to the knowledge of the directors, with the Dutch and Australian authorities for the necessary concessions to enable telegraphic extensions to be carried out from Singapore to those countries, and soundings are about to be taken for a cable route from Singapore to Hong Kong. From the extreme point of the Dutch possessions to the Australian continent the distance is only 1,130 miles; and a cable 1,780 miles in length will connect Singapore with Hong Kong *viâ* Cochin China. The directors intend, after the completion of their cable, or earlier if so advised, to adopt such measures as may ensure the carrying out of the above extensions. When such a system is completed there can be little doubt that the messages passing over the Singapore and Ceylon cable will exceed the present estimate of the British Indian Company—namely, 300 per diem. In the meantime, looking to the importance of Singapore, and the fact that messages will reach it at once by steamers from China, the Philippines, Cochin China, and Java, it is considered a moderate estimate that 75 messages will pass each way daily. The total length of the present Singapore cable will be 1,756 miles, and the type is similar to those manufactured by the Telegraph Construction and Maintenance Company for other deep sea lines, with such improvements as recent experience has suggested.

A contract entered into with the Telegraph Construction and Maintenance Company provides for the manufacture and laying of this company's cable in the year 1870, at a cost of £440,000, of which the contractors will take £130,000 in fully paid shares. £50,000 of these fully paid shares are to be reserved until this company's engineers have certified that the whole line has been successfully laid, and has continued for thirty consecutive days equal to the standard of insulation prescribed by the specification. A tariff has been arranged with the Falmouth, Gibraltar, and Malta, the Anglo-Mediterranean, and the British Indian Telegraph Companies, by which the charge for a message of twenty words from England to Singapore will be £4 4s., of which this company will receive £1 7s. The tariff for local messages between the termini of this company's cable is intended to be £1 10s. Calculating the daily number of messages at 150, of the average length of thirty words, at a tariff of 27s. per twenty words, and allowing 330 working days, the gross annual revenue would be £100,237. Deducting from this £16,000 for working expenses and £10,000 for a reserve, a balance is left of £74,237, yielding upwards of 16 per cent. per annum on the capital; and it may be fairly assumed that this income will be doubled as soon as the projected extensions are carried out. In these days of successful telegraphic enterprise, we can have no doubt that the public will come forward to the support of the undertaking, and that it will prove a practical success.

MANUFACTURE OF CAPS AND CARTRIDGES.

No. XI.

THE operation of filling the cases of the sporting cartridges is performed in a manner similar to that already described for those intended for less peaceful purposes, and it is not necessary therefore to recapitulate our previous description. An almost identical process introduces the charge of shot, and a wad being placed on top, the end of the case is solidly closed up, and the manufacture complete. It is rather curious that the finished cartridges do not constitute, as might be expected, the chief trade in the article. It is the empty cases that furnish the principal contingent, which are despatched to the gunsmiths and ammunition sellers, independently of large numbers which are supplied direct to sportsmen who prefer filling their own cartridges. They probably imagine that they have some secret respecting the relative proportions of powder and lead which ensures more accurate shooting.

With a few unimportant modifications the manufacture of the central-fire cartridges is conducted on the same principles as those already alluded to. The cartridge cases intended for carbines and pistols, including revolvers, are composed wholly of brass instead of pasteboard, or paper and tinsel, but the succeeding operations do not vary from those undertaken in the other examples. Besides those we have mentioned, a large number of other types of cases are constructed at the establishment of M. Gevelot, but as they are not exported in any considerable quantities, it is unnecessary to refer to them in detail. The only one deserving mention is the example in which the brass end or socket is surrounded by a metallic ring or collar. This description has been extensively used for guns and revolvers. The object aimed at is to obtain a large rim or edge. If this be gained at the expense of the brass socket, the latter will be very considerably reduced in thickness and weakened, and, moreover, the rims so obtained will

* See the MECHANICS' MAGAZINE for October 1, p. 238.

be uneven in their own thickness and diameter. Instead of this method, another is adopted, which fulfils the required conditions most successfully. A disc is cut out of a piece of iron and pierced with a hole corresponding in diameter to that of the exterior of the socket of the cartridge case. It is then slipped over the socket from the front end, and is prevented from sliding off by a slight swelling of the back extremity of the socket. The case is then subjected to a strong pressure in a suitable mould, and the disc tightly fixed in its place between a couple of rims raised on the socket upon each side of it. For especial purposes the cartridge cases for guns are manufactured all of copper, and, in order to increase the range of some of the sporting cartridges, the charge is enclosed in an extremely fine iron wire net. The theory is that for a certain distance the charge would act like a ball, and when the net broke and the charge spread its destructive effect would be greatly increased. At present, no experiments have been undertaken to practically substantiate this expectation.

Having brought to a termination the description of the articles manufactured by M. Gevelot, a few words may be now said regarding the premises themselves, in so far as they are connected with the welfare and comfort of those inhabiting them either temporarily or permanently. The enterprising proprietor speedily discovered that in order to retain good and reliable workmen upon the books of the establishment, it became absolutely indispensable to provide them with habitations in the immediate vicinity. Accordingly, he laid out a street alongside the principal workshops, and on the side opposite to them he built a terrace or row of houses three stories in height, counting the ground floor as one. At a short distance from this row of buildings, and connected with it by a timber gallery, are three pavilions, whose pointed tops break the monotonous appearance of the hard straight sky-line presented by the row of houses. The different flats and apartments are reached by staircases and external corridors or galleries, very similar in construction to those belonging to some of our "industrial dwellings." From these buildings a fine view of the scenic expanse is obtained, embracing the hills of Meudon and Bellevue, the river Seine as it encircles with its waters the Isles of Billancourt, and the sharp, clearly-defined contours of the arches of the viaduct of the Western Railway. According to the taste and habits of the tenants so does the internal appearance of the habitations vary. The arrangements for comfort, and even comparative luxury in some instances, are very complete, while in others there is a great deal to be desired on the same score. As a rule, the old hands are all pretty well "set up" in furniture and effects, and it is easy to perceive that they intend to be permanent tenants. Small gardens are attached to most of the dwellings, which are carefully attended to and maintained in a blooming condition. The disposition of the apartments is identical in every instance. A kitchen, sitting room, and bed room comprise the suite. These rooms are not let to the workmen gratuitously, but a rent of eight shillings is deducted at each pay day, which occurs every month. As frequently more than one member of a family is employed on the premises, this deduction is scarcely felt, and obviates much of the discomfort and misery that is so often attendant upon rent-time owing to the improvidence of the working classes. This small town occupies an area of about an acre and a half, and contains seventy-five tenements. Its erection, including the value of the land, cost £8,850. With women and children, the total working staff of M. Gevelot averages over 2,000 persons. Among these must be included a large number of fitters, mechanical engineers, turners, and others, whose duty is to repair and keep in order all the various machinery and apparatus, and, when required, to construct new ones for especial purposes.

Before drawing to a close our articles on the "Manufacture of Caps and Cartridges," it is to be regretted that there is a dark side to the picture. But so it is. The system of surveillance—it might almost be termed espionage—that the "paternal government" is so fond of indulging in, is not neglected in this instance. In the first place, it is included in the category of unhealthy establishments, and in consequence subjected to the rigorous regulations provided for their especial behoof. The manufacturers of fulminating powder can only obtain provisional permission to carry on their business. This permission can be revoked at any time by the authorities who grant it, so that the proprietors of an establishment of this nature are placed in a very trying and unfair situation. After erecting the works and starting the business, it all depends upon the caprice of the Administration whether it may remain a permanent concern or be closed almost before it has got into working order. Under such circumstances it is a marvel that any one would embark in an enterprise of the kind. Moreover, when the articles such as caps and cartridges are manufactured, they cannot be exported without express permission of the Minister of War, while foreign firms may import as many as they please by paying the import duty of ten per cent. *ad valorem.* This arrangement altogether prevents the French manufacturers from taking foreign contracts, since they cannot be sure whether they would be allowed to carry them out. They are thus placed at a great disadvantage in comparison with our English firms. Another evil, which arises from the small difference that exists in many instances between sporting cartridges and those intended for war, is that the exportation of the latter is strictly prohibited, and it is easy to perceive that, by a slight stretch of arbitrary power, the former might be brought under a warlike designation. Although the premises at Moulineaux are not on a scale of such colossal magnitude as those at Essen (a full description of which appeared in our columns of 1866), yet if the proprietor of the former was as untrammelled in his actions as M. Krupp, he would not hesitate to add considerably to the size of his present manufactory. Instead of turning out half a million cartridges per diem, the yield might easily be raised to one or two millions. Past events have proved, both in the old world and the new, that the fate of an army, of a fleet, and of an empire, may at any moment depend upon the efficient or inefficient construction of arms and ammunition.

SIR JOHN FRANKLIN.

SOME important and interesting facts bearing upon the unfortunate Franklin expedition have been made known by Captain C. F. Hall, the eminent Arctic explorer, who recently returned to New Bedford from a five years' search for the remains of Sir John Franklin's companions. Captain Hall has unmistakable evidence of the fate of Sir John and his party. Although the evidences found are conclusive as to the fate of the party, Captain Hall is confident that if a large and well-organised expedition should spend one summer on King William's Land, where records, "beyond doubt," are buried, the complete history of the fate of Franklin's last expedition would be found. These manuscripts are supposed to be buried in a vault a little inland or eastward of Cape Victory, the Captain at one time being within 75 miles of there; but a stampede of the natives accompanying him as an escort forced him to retrace his steps. From the imperfect description given by the Esquimaux of the condition of Crozier's party of 105 men, the Captain is satisfied that they were suffering from the scurvy, as nothing but sickness would have kept so experienced an Arctic traveller as Crozier from the game which was in abundance within 75 miles of where he and his party perished. The relics brought back number about 150, and were as many as could be conveniently carried, although there were hundreds of them in the possession of the natives. Those brought back were obtained from the natives through the (with them) all powerful agency of presents—a needle being considered a fair equivalent for a silver fork or spoon. Captain Hall writes :—"I could have gathered great quantities—a very great variety—of relics of Sir John Franklin's expedition, for they are now possessed by natives all over the Arctic regions that I visited or heard of—from Pond's Bay to Mackenzie River. As it was, I had to be satisfied with taking upon our sledges about 125lb. total weight of relics from natives about King William's Land. Some of these I will enumerate :—A portion of one side (several planks and ribs fast together) of a boat, clinker built and copper fastened. This part of a boat is of the one found near the boat found by M'Clintock's party. A small oak sledge runner, reduced from the sledge on which the boat rested. Part of the mast of the 'North-West Passage' ship. Chronometer box, with its number, name of maker, and the Queen's broad arrow engraved upon it. Two long heavy sheets of copper, 3in. and 4in. wide, with counter sunk holes for screw nails. On these sheets, as well as on most everything else that came from the 'North-West Passage' ship, are numerous stamps of the Queen's broad arrow. Mahogany writing-desk, elaborately finished and bound in brass. Many pieces of silver plate—forks and spoons—bearing crests and initials of the owners. Parts of watches. Knives, and very many other things." Wherever Captain Hall found that Sir John Franklin's companions had died, he erected monuments, then fired salutes and waved the Star-spangled Banner over them in memory and respect of the great and true discoverers of the North-West Passage.

PHOTOGRAPHY.

MR. BLANCHARD ON THE WET PROCESS—ALKALINE WET PLATES—EFFECTS OF AGE ON COLLODION—PHOTOGRAPHIC COMETS.

MR. VALENTINE BLANCHARD, one of the best workers of instantaneous processes in London, has just published, in the "Journal of the Photographic Society," some experiments on plates sensitised in an alkaline nitrate of silver bath. To get clean pictures, free from fog, a trace of free acid in the bath is almost always necessary, though, with some samples of collodion, the bath may be in a perfectly neutral state. An alkaline bath in the wet process is, under ordinary conditions, perfectly useless. Mr. Blanchard points out that, when a collodion is used containing an ammoniacal salt in excess of the other bromo-iodising compounds, clean pictures could be obtained. In his experiments, cadmium and ammoniacal salts were used in the collodion; the first plate fogged, but every successive plate gave better pictures, till, after a few trials, clean pictures were the result, produced apparently by the formation of nitrate of ammonia in the bath.

Mr. Sutton's pamphlet on alkaline wet plates having been unanimously condemned by all reviewers because it withheld the formula of the necessary collodion, kept on sale by Mr. Sutton's agents, Mr. Sutton at last has made known full particulars as to its composition, as follows:—

Ether, S. G., ·725 . .	4 fluid drachms
Alcohol, S. G., ·810 .	4 „ „
Pyroxyline . . .	5 grains
Bromide of cadmium .	5 „
Bromide of ammonium	5 „

He says that no matter what pyroxyline be used, he knows of none that will make a collodion capable at first of giving a film free from wrinkles and listers. The collodion must be kept for a

time—say a few months—before it ceases to give a skinny film, and forms one having the soapy, powdery consistency so necessary in dry plates. Collodion made with pure materials and cadmium salts should keep for years, and, for a considerable time, should improve in working qualities. He says that good old collodion never exceeds a pale yellow tint, and that, with a pure nitrate bath, it will yield negatives which require no intensification.

As yet only one comparative trial seems to have been made of the relative rapidity of Mr. Sutton's new process and the old ones. Major Russell narrates in the "Illustrated Photographer" how he coated one half of a plate with tannin and the other half with the alkaline gelatine organifier. On developing the picture, he could not see any decided difference between the two halves.

Comets, with tails attached, sometimes are troublesome by making their appearance upon the picture during the developing process. They also manage, as a rule, to come out just in the right place to spoil the picture—across the nose or mouth of the sitter for instance. They are far more common with iodised than with bromo-iodised collodion; hence a remedy often applied was to add more bromide. Naturally enough, these facts suggested that the fault lies in the collodion when comets appear, but it is not so. They are caused by imperfectly cleaned glass plates, and are very often seen when depositing metallic silver by the chemical method upon sheet glass to form mirrors, though, in such processes, no collodion at all is employed. The fact is that iodised collodion is more sensitive to disturbing influences than bromo-iodised collodion, so that the comets appear in the one case more frequently than in the other.

NOTES ON RECENT DISCOVERIES IN SCIENCE AND THEIR PRACTICAL APPLICATIONS.

THE OCCLUSION OF HYDROGEN BY NICKEL—A NEW HYDROMETER—COPPERSMITHS AND CHOLERA—THE COLOURS MOST READILY DISTINGUISHED—THE DYNAMOMETER AND WASTE HEAT.

THE small cubes of nickel, such as we find in commerce, have been found by M. Raoult to be in an eminent degree porous, and to have, like palladium, the power of absorbing hydrogen. One cube of metal will occlude 165 times its volume of gas. We are not yet informed whether any increase of bulk is occasioned by the entry of the gas or what alteration in density takes place. The author would seem to regard this as a case of simple absorption, such as happens with charcoal; for it appears that, once hammered, the metal loses its porosity and power of absorption.

A new kind of hydrometer has been invented by M. Baudin, which we have no doubt will give very accurate results with strong spirits. In this instrument the strength of the spirit is measured by its expansibility. A thousand measures of absolute alcohol at 50degs. become a thousand and seventy-nine at 170degs., or a little below its boiling point. With mixtures of alcohol and water the rate of expansion is not uniform, but no doubt M. Baudin's tables have been constructed upon special experiments.

A fortnight ago we published a paper by Dr. Burg, of Paris, showing the immunity from cholera which coppersmiths and others working with alloys of copper enjoy. We have now a statement by Dr. Clapton, of St. Thomas's Hospital, that the same fact is observable in London. He has found by inquiries at various works that copper workmen have been free from cholera and diarrhœa, although their neighbourhoods suffered severely during the great epidemics. This is a remarkable fact, deserving the serious attention of medical authorities. Dr. Clapton's observations have extended beyond those of Dr. Burg. He has been able to prove that by handling copper some absorption of the metal into the system does certainly take place. Copper-workers get green stains on the gums immediately above the teeth, just as painters and lead-workers get a dark, almost black line. They have a bluish-green perspiration, and, if afflicted with ulcers, the exuding matter is of a greenish colour. But their occupation, unlike that of painters and water-gilders and others, seems to bring them no specific disease.

Experiments made to ascertain what colours are most quickly and easily perceived by the eye seem to show that bright yellow is the colour most easily distinguished, and violet and red are the least readily recognised. After yellow, blue is most quickly seen. These experiments may be of some value in improving our system of railway signalling. The colours most readily distinguishable at the greatest distance are obviously the best to employ for signals. Now, according to these experiments, red comes last or last but one, and green stands but just before it. Bright yellow and blue, the colours most easily recognised, would, therefore, seem to be preferable for signal lights.

In connection with this we may mention an interesting fact, but one of no practical importance further than showing that the perceptions of the lowest animals seem to accord with our own. When a basin of water containing some of those active little animals water-fleas is surrounded with blackened paper the animals sink into inactivity, but when a strong beam of light is sent through a hole in the paper, they spring at once into activity and collect in the illuminated part of the water. Further than this, if a spectrum be projected through a slit in the paper, the greater number of animals collect in that part of the water illuminated by the orange yellow rays, and the fewest in the line of the violet, which would seem to indicate that they too most readily perceive yellow light.

Dr. Mayer, the celebrated physicist, has now perfected an instrument he calls a dynamometer, which, adapted to engines of 20-horse power and upwards, reads simultaneously measurements of force in the form of heat as well as of pressure. We have no account as yet of the instrument, which is obviously of more scientific than practical value. The same philosopher, dealing with the question of the conservation of force, has come to the conclusion that the large amount of force which is lost in the form of heat in all mechanical operations can never be utilised. Heat, he tells us, is the cheapest possible form of force, mechanical is far dearer, and electricity the dearest force of all. Hence it would never pay to transform waste heat into any other form of force.

ENGLISH AND CONTINENTAL INTER-COMMUNICATION.

By Mr. Perry F. Nursey.

AT a meeting of the Society of Engineers, held on Monday evening, the 18th of October, the President, Mr. F. W. Bryant, in the chair, the following paper was read:—

One of the most prominent and important questions of the present day, and one to which a very wide-spread attention is being given, is that of providing a more easy and rapid system of intercommunication between England and France than we at present possess. Nothing is more obvious than the necessity which exists for improvement in this direction. The steam packet service between England and France—which is in fact a service between Great Britain on the one hand and Europe and the East generally on the other—is about the worst we have. It is an undoubted fact that the great majority of passengers crossing the Channel suffer—short as is the sea passage—extreme discomfort from sea-sickness and want of shelter during bad weather. Not unfrequently the traveller from India or from America finds the British Channel the most unpleasant part of his journey, and he sometimes looks forward with more anxiety to the state of the Channel than to the heat of the Red Sea or the passage of the Atlantic. In the case of America, he will often select a French or an English vessel, according to the country which he desires to reach, in order to avoid the Channel crossing, rather than from any other consideration. There are now, exclusive of the routes by Ostend and Antwerp, 310,000 passengers per annum to be provided for, of whom 142,000 travel by Calais, as the mail route. Those numbers are undoubtedly capable of great augmentation on greater facilities and increased comfort being afforded. But the existing steam vessels, restricted as to their dimensions for want of better pier and harbour accommodation, are disproportionate to the service. Larger vessels, with less movement in rough weather, more shelter, and better accommodation generally, would do much to mitigate the discomforts of the sea passage. Pending the successful issue of other more extensive and more permanent projects it would be well if these improvements were effected. But larger vessels cannot be employed for a fixed service until better provision is made for embarking and disembarking passengers, especially on the French coast. The Society of Arts, ever on the alert to improve the social position of mankind, has offered its gold medal for the best design for a steamer which shall afford the most convenient shelter and accommodation to passengers on the deck of the vessel crossing between France and England. The attendant circumstances of the case, however, oblige the society to specify that the steamer is not to exceed in tonnage and draught the best vessels now in use between Folkestone and Boulogne. There have also been other schemes propounded at various times for vessels of special build suited to the present harbour accommodation. Into these propositions, however, it is not our present purpose to enter. The growing necessity for a radical improvement teaches us that they can only be regarded as temporary expedients which must give way in course of time to more permanent works. We will therefore proceed to the consideration of the more important and extensive projects which have been placed before the public during the last few years. These consist of tunnels driven beneath the bed of the sea; submerged roadways and tubes; large ferryboats carrying the trains on board, bridges across the Channel, and embankments.

If we glance at the history of the question we shall find it to extend further back into the past than is generally supposed. Something like a score of projects for effecting direct communication between the two countries have been proposed from first to last. Up to the close of the year 1866 three French projectors had proposed tunnelling under the Channel; five English and two French inventors had proposed submerged tubes; one Frenchman proposed an arched roadway or tunnel, and an Englishman a bridge. Since that time there have been some seven or eight proposals for effecting that object; to these attention will presently be specially directed. The idea of tunnelling is much the oldest; a French engineer, M. Mathieu, nearly seventy years since, considered the scheme practicable. He worked out the details of his plan and laid them before Napoleon, then First Consul. In 1856, M. Thomé de Gamond proposed a tunnel scheme which received more than ordinary notice. The plan was to form in the Channel thirteen islands by carrying materials out to sea, to sink shafts through them into the earth below the bed of the Channel, and then tunnel from one to the other. A commission of engineers was appointed and they carefully examined M. de Gamond's data and conclusions, and particularly his geological investigations, which were the first steps taken to demonstrate practically the nature of the strata beneath the Channel. These investigations supported the theory that the Straits of Dover were not opened by a sudden disruption of the earth at that point, but had been produced naturally and slowly by the gradual washing away of the upper chalk; that the geological formations beneath the Straits remained in the original order of their deposit, and were identical with the formations of the two shores, being, in fact, the continuation of those formations. Acknowledging the scientific accuracy of M. de Gamond's conclusions, the commission recommended an appropriation of £20,000 to make preliminary examinations. The plan, however, was finally rejected on account of its interference with the navigation of the Straits. The submerged tube projectors of that time, with one or two exceptions, appear to have given the subject less study than the advocates of the tunnel. It was a work very easily effected: you only have to construct your tube in sections; float them over the proposed line of route; sink them and connect their ends; pump the water out, and the thing is done. Hear how one of these facile gentlemen describes his project:—

"My plan is simply to construct wrought-iron tunnels in separate divisions; to sink them on the bed of the water, and then to connect them. It will be admitted that to construct such a tunnel would be an easier matter than to build iron vessels, as it would be the same shape the whole length. Then to sink it on the bed of the water would be the work of a few hours for each division of 400ft. in length." A momentary fit of

reflection, however, seizes him when he has sunk his lengths of tube, for he says:—"Perhaps the part of the work which will appear the most complicated will be to connect the divisions under water." But, quickly recovering himself, he adds:—"The operation will be attended with no extraordinary difficulty to those who can remain during half an hour in deep water." Turning to the shore ends he observes:—"As regards that part of the tunnel which would be near the shore, it would be sunk under ground, and covered with stones fastened together, so as to render them immovable. . . . . Then the railway will be formed in forming the tube; there will be no hills to cut through, valleys to fill up, nor arches to build; in short, the sum total of the work is comprised in the tunnel itself." Warming with his subject he grows bolder and says:—"Supposing the divisions to be 1,000ft. in length; in that case, only 104 divisions would be required to join the rails of the South-Eastern Railway with those of the Calais and Paris. Now, supposing each of these divisions would cost £40,000, the cost of the whole would be £4,160,000; and if we allow for the expense of throwing them in deep water, of connecting them, of building stations, &c., on a magnificent scale, it will, I believe, be found that the sum of £8,000,000 sterling would be quite sufficient to complete the submarine railway." Really the manner in which this gentleman speaks of throwing into deep water iron tubes a thousand feet in length, and capable of containing a railway, is most refreshing, and must have been very encouraging to the sea-sick continental traveller.

Turning to another project we find it to consist in crossing the English Channel by means of a tube made of strong plate iron or cast iron, lined and prepared for that purpose, and which, placed at the bottom of the sea, should contain the two lines for the trains which would run within it. The slope given to the submarine railway would admit of a motion sufficiently powerful to enable the carriages to cross the Channel without a steam engine. The greatest depth of the sea at the middle of the Channel will admit of the construction of inclined planes, by means of which the train would be enabled to reach a point where a stationary engine, or atmospheric pressure, might be employed in propelling the train to the level of the land railways of France and England.

Another visionary does not place his tube on the bottom, but proposes to situate it at a uniform depth from the surface, by means of ties below (and buoys above, if necessary), at suitable intervals. He says:—"The continuation of the tunnel into the shore on either coast I should dispense with; and, in order that it should have a partial freedom of motion, it should terminate with solid ends before reaching the shores. To these points, chain piers should extend; or, if strict economy were aimed at in this item, the communication might be by small steamers." As the tunnel or tube in question contains only a single line, the projector proposes pushing one way, and pulling the other; or, he says, electricity should, if at all practicable, be the motive power. After proposing, as the principle of construction, something analogous to the cooper's craft, he continues:—"When the tube was completed from end to end, favourable weather would be waited for, and the work of lowering would then be accomplished, nearly as follows:—The airtight interior of each pontoon would be connected by an ample length of flexible pipe to an air pump of adequate power, on board a vessel anchored at a distance corresponding to that intended for the mooring weights. The two lines of vessels should be manned by steady men, each crew under a trustworthy leader. Athwart the vessels would be laid, from the shore, the wires of an electric telegraph, communicating with an apparatus on board of each; so that, at a preconcerted signal, the abstraction of the air from the pontoons should be commenced simultaneously at a given time, and carried on at a given rate. By this means, the pontoons, gradually deprived of their buoyancy, would yield to the pressure of their burden—the buoyancy acquired by which as it entered its future element would be overcome by the weights with which, throughout its length, it was loaded, and which would speedily sink it to its prescribed depth. It would be when the tube reached the water that the mooring weights, having been preparatorily slung under the vessels above mentioned, would, at another signal by the electric telegraph, be simultaneously let drop into the sea, and drag down their charge along with them."

We will only briefly notice two more of these easy-going gentlemen, whose ideas slip out so glibly that practical men fail to grasp them, and these are the proposer of the arched roadway or tunnel on the bottom, and the proposer of the bridge. The former, with 40 subaqueous boats, of which he was the inventor, 1,500 sailors and navvies, 4,340,000 cubic yards of material, and £10,000,000, undertook to construct a tunnel, by means of which the Straits could be crossed in 33 minutes. The mammoth bridge projector would make in the Channel 190 pedestals, 300ft. square at the bottom, consisting of rocks bolted and lashed together, gradually rising at an angle of 75deg., till they formed each an insular plain, 150ft. square, 40ft. above the level of the sea. On these he would build towers 100ft. diameter, 260ft. high; crowning the whole with a tubular bridge 50ft. deep and 30ft. wide.

CHALMERS.

We will now turn to the more practical projects which have since been advanced, noting them somewhat in the order of their appearance before the public. First, then, comes the proposition for a Channel railway, by the late Mr. James Chalmers, whose name is connected with some very valuable improvements in the construction of armour-plated ships and forts, but which his premature death prevented him perfectly developing. Mr. Chalmers' plan was to have a tube of boiler-plate iron, lined with brickwork, laid on the bed of the sea, and having ventilating towers at intervals. Through this tube the railway was to be carried. His project provided for an unbroken double line, connecting the railways of England and France by easy gradients, capable of carrying all ordinary trains at the usual speeds on the best roads, and of insuring perfect safety and comfort. It was to offer no obstruction to the navigation of the Channel, and Mr. Chalmers estimated that the work could be completed in three years for £12,000,000. The principal features of the work, as proposed in 1866, were two strong iron tubes, cased with timber and lined with brick, each containing a single line of railway, and reaching from shore to shore on the bottom of the Channel. The displacement and weight of these tubes was designed to be so nearly balanced that both in submerging and when in position they would not be subjected to any appreciable lateral strain. There would be a slight excess of displacement, which would be effectually overcome by the materials with which the tubes were to be covered. Mr. Chalmers held that as the current alternated up and down Channel with the rise and fall of the tide, the embankment would silt up eventually, and become a solid, impermeable mass, having the appearance of a ridge reaching from shore to shore, about 150ft. wide at the base, 40ft. high, and from 40ft. to 120ft. below the level of low water. Mr. Chalmers proposed to have three ventilators, one in mid-channel, and one about a mile from either shore. Thus the main portion of the work would be 18 miles in length; and this divided by the deep-sea ventilator, would give two sections of 9 miles each. Consequently, a train could never be more than 4½ miles from an opening. From those and other points, the air was to be withdrawn through pipes by machinery situated in the central ventilator, or on the shore embankments, which would cause currents of fresh air to rush to those parts most distant from the ventilators.

The tubes were to be circular in form, and made of boiler plate, double-riveted and caulked. The circular form was to be preserved, and the tubes were to be strengthened by iron girder frames surrounding them. To the outer flanges of these frames the timber casing would be attached by bolts; and the spaces between the timber casing and the tube proper filled with concrete. Finally, the interior would be lined with the most durable description of brickwork.

The timber casing, properly caulked, says Mr. Chalmers, would be equal in strength and watertightness to the plating of a frigate; the tube itself would be as tight and stronger than a steam boiler or iron ship; and the concrete packing between the planking and the tube would also be impermeable to water. Thus, not only is a double or treble precaution taken against leakage, but the iron would be protected, both without and within, from any injurious effects that might result from contact with sea water; though, at the depth at which these tubes would be placed, such contact, even if possible, under the circumstances, would not be so injurious as if they were nearer the surface. Maury, in his "Physical Geography of the Ocean," states as follows:—"Count Marsigli divides sea water into surface and deep-sea water; because, when he makes salt from surface water (not more than 6in. below the upper strata), this salt will give a red colour to blue paper; whereas the salt from deep-sea water will not alter the colours at all. The blue paper can only change its colour by the action of an acid. The reason why this acid (iodine?) is found in surface and not in deep-sea water is that it is derived from the air." Hence, argues Mr. Chalmers, the bottoms of iron ships—when the interior skin of the iron is kept clean and well-painted—appear to suffer little or nothing from the action of the water on the exterior. But, even if the iron of the tube were to suffer by oxidation in forty or fifty years (a circumstance which, from its position, Mr. Chalmers considers is far from probable) the embankment, by this time silted up into a solid mass, the timber casing, the concrete and interior lining, would of themselves ensure the permanency of the Channel railway.

The ventilator in mid-channel was to be a circular mass of iron and stone, 100ft. in diameter, and 210ft. in height, 168ft. of which would be below the water-line. When finished it was to weigh about 100,000 tons, and displace 50,000 tons of water. It was to be surrounded by, and imbedded in, the embankment that covered the tubes, which at that point was to be raised to a height of about 80ft. The other ventilators were to be ordinary air-shafts near the end of the shore embankments, which would be run out, breakwater fashion, about a mile from either shore to a depth sufficient for navigation over the tubes. The tubes were to be made in lengths of 300ft. or 400ft., were to be fitted with temporary bulkheads lowered into position, and united by a somewhat delicate submarine operation.

HAWKSHAW.

Mr. Hawkshaw's attention has been directed to the subject of a tunnel for connecting the railway systems of England and France, and he has made a practical geological examination of the Channel and the two coasts, the results of which are of great value in connection with the question. As Mr. Hawkshaw's scheme appears to have absorbed those of M. de Gamond and Mr. Low, an English mining engineer, it will be as well to trace the history of the combination concurrently with the development of the scheme. The project has been worked out under the auspices of a committee by Messrs. John Hawkshaw, James Brunlees, and William Low, English engineers, in conjunction with MM. Paulin Talabot, Michel Chevalier, and Thomé de Gamond. These gentlemen have reported to the committee of promoters of the undertaking, and that document supplies the following facts and valuable information, from which we gather the history of the scheme.

Following the order of the report, we will first take Mr. Low's proposition. That gentleman has for several years past conceived the idea of connecting the railway systems of France and England by tunnelling, and as a practical mining engineer he has devoted his attention in the first place to securing the efficient ventilation of the work both during construction and after completion. In most of the tunnel schemes it is proposed to effect ventilation by means of towers in the sea, more or less numerous, and differing in magnitude and cost. Mr. Low proposes to dispense entirely with shafts in the sea, and to commence the work by sinking pits on each shore, driving thence, in the first place, two small parallel driftways or galleries from each country, connected at intervals by transverse driftways. By this means the air could be made to circulate as in ordinary coal mines, and the ventilation be kept perfect at the face of the workings. Another advantage attending this mode of proceeding is that these headings could be driven from shore to shore at the minimum of cost, and the practicability of executing the proposed tunnels demonstrated without extravagant outlay. The driftways were to be turned into two tunnels suitable for the ordinary locomotive traffic of the railways to be connected by this work. Having settled the principle of the construction of his tunnels, Mr. Low investigated the geological nature of the shores of the Straits. From personal examination of the most careful character, he verified the data of Mr. Phillips and of other eminent geologists who have made the geology of the shores of the Straits, and the subject of the continuity of the strata under the sea, their special study. He also examined the borings for the artesian well at Calais, the artesian well at Harwich, and several other wells of less magnitude, by all which the regularity of the strata was proved. He found everywhere that the deductions of the geologists were sound; and at the line which he ultimately fixed on for his proposed tunnels, viz., about half a mile west of the high light of the South Foreland, and at four miles west of Calais, the tunnels could be made almost entirely through the lower or grey

chalk, which, owing to its comparative freedom from water, and the general absence of cracks and fissures in it, offered the most desirable stratum for working in. Mr. Low laid his plans before the Emperor of the French in April, 1867, and his Majesty desired Mr. Low to proceed to organize the means of carrying out his project, and to come to his Majesty again when he was prepared to lay definite proposals before him.

In an international work of this nature, it was desirable to obtain the co-operation of a French engineer, and Mr. Low therefore put himself in communication with M. de Gamond, who placed his geological studies and sections at Mr. Low's disposal. Mr. Low then laid the results of his and M. de Gamond's labours before Mr. Brunlees, who, after a careful examination of the project, consented to co-operate with Mr. Low and M. Thomé de Gamond for the prosecution of the proposed work. In accordance with the desire of his Majesty, a committee of French and English gentlemen was formed in furtherance of the project.

For some years past Mr. Hawkshaw's attention had been directed to this subject, and ultimately he was led to test the question, and to ascertain by elaborate investigations whether a submarine tunnel to unite the railways of Great Britain with those of France and the continent of Europe was practicable. With this object he caused to be made a careful examination of the geology of the Channel and of the French and English coasts, and had a chart prepared, based on that examination, and on such further information as he could procure. From a careful consideration of these geological investigations, Mr. Hawkshaw arrived at the conclusion that it was desirable that the tunnel should pass as far as possible through the lower chalk, for it appeared to him that if an attempt were made to carry it through the strata lying under the chalk, it would have to penetrate material of variable nature, some of which would be soft, and through which it would be undesirable to construct a submarine tunnel. It also seemed to him desirable to depress the tunnel as much as possible below the upper or white chalk, and to carry it as far as practicable through the lower or grey chalk, which is less permeable to water than the upper or white chalk. But when he had proceeded thus far, Mr. Hawkshaw felt that more accurate information than could be arrived at by geological inquiries only, however carefully conducted, was necessary. He had ascertained that at Calais an artesian well had been sunk to a depth of about 1,000ft., and from the records of this work he obtained the particulars of the strata at that point. This well, which failed to procure water, was some distance from the spot on the French coast where, from the geological inquiries, it seemed desirable that the submarine tunnel should be placed. He therefore decided to make borings on each coast, at the ends of the line which approximately seemed the best position for the tunnel, and also to examine the bottom of the Channel for some distance on each side of that line. Accordingly, at the beginning of the year 1866 a boring was commenced at St. Margaret's Bay, near the South Foreland; and in March, 1866, another boring was commenced on the French coast, at a point about three miles westward of Calais; and simultaneously with these borings an examination was carried on of that portion of the bottom of the Channel lying between the chalk cliffs on each shore.

The boring on the English coast was satisfactorily completed in 1867. It was carried through the chalk and into the green sand, which was reached at a depth of 540ft. below high water. The boring on the French coast was continued from the surface to a point about 520ft. below high water. It passed through the upper chalk into the lower or grey chalk. This was completed at the end of 1867. It was Mr. Hawkshaw's intention to have carried this boring also entirely through the chalk, but in attempting to substitute larger boring tubes, the hole was accidentally filled up with sand and shingle from the top. The results, however, arrived at from this boring seem sufficient, and accorded very nearly with the records of the Calais well, and with the geological survey previously made; so as not only to confirm their accuracy, but to lead to the deduction that at the site of this boring the chalk would extend to, and the green sand be reached at, a depth of about 750ft. below high water.

For the examination of the bottom of the Channel a steamer was engaged and suitable apparatus provided, by means of which the bottom could be pierced for a short distance and specimens could be raised from the bed of the Channel. On shore suitable points can be selected for examining the strata; whilst at sea many of the examinations made from soundings fall on superficial deposit. A survey of the Channel, therefore, cannot be so complete as a survey of the coasts. Nevertheless, the result of the examination seems to indicate that across the Channel the position of the chalk is nearly identical with that deduced from the previous geological inquiries.

The principal practical and useful results that the borings have determined are, that on the proposed line of the tunnel the depth of the chalk on the English coast is 470ft. below high water, consisting of 175ft. of upper or white chalk and 295ft. of lower or grey chalk; and that on the French coast the depth of the chalk is 750ft. below high water, consisting of 270ft. of upper or white chalk and 480ft. of lower or grey chalk; and that the position of the chalk on the bed of the Channel, ascertained from the examination, nearly corresponds with that which the geological inquiry elicited. It also appears probable that there is no great fault or serious interruption in the continuity or regularity of the strata between the two shores on the proposed line of tunnel. The results of these investigations were submitted to M. Michel Chevalier and M. Paulin Talabot, and they were put in possession of all the information that had been obtained.

Such, then, is the history of the separate investigations which have been made into this important and interesting subject, and the general nature and result of those investigations. We will now proceed to the conclusions at which the members of the Committee of Engineers arrived after consulting together and comparing the several data.

They submit that it is evident that at some sufficient depth below the bottom of the Channel a tunnel could be constructed, so that, as regards superincumbent pressure only, it would be analogous to constructing a tunnel of similar length through a mountain so high as to prohibit intermediate shafts; it is further evident that any possible irruption of sea-water may be avoided by going deep enough below the bottom of the Channel. On the other hand, they observe that there is a limit to the depth at which the tunnel can be carried, from the necessity of approaching it from the shore and obtaining gradients for those approaches suitable for railway traffic. If the tunnel were carried through the upper or white chalk, or chalk with flints, apart from a possible irruption or percolation of water from the sea, fresh water might be encountered to the usual extent that it is met with in that formation. But the tunnel can be depressed so as to pass mainly through the lower or grey chalk, which is less permeable, and where the quantity of fresh water would be comparatively unimportant, provided no great fault or dislocation of the strata exists—and the investigations lead to the conclusion that no such great fault does exist. It is probable that at the depth below the bed of the Channel at which it would alone be prudent to carry the tunnel, any fissures that may occur in the chalk have been filled up, and that from this circumstance and from the nature of the lower chalk no more water will be met with than can be overcome by pumping.

With regard to the execution of the work itself, the Committee of Engineers consider it proper to drive preliminary driftways or headings under the Channel, the ventilation of which would be accomplished by some of the usual modes adopted in the best coal mines. All other questions in relation to the construction of the permanent tunnels would be decided from the experience gained in making the driftways, and it might even be deemed advisable to commence the formation of the permanent tunnels before the completion of the driftways, if circumstances indicated the desirability of that course. They propose that the tunnel should be of the ordinary form, sufficiently large for two lines of railway, and to admit of being worked by locomotive engines, and artificial ventilation could be applied. The desirability of adopting other modes of traction is left for future consideration.

Finally, the following general conclusions are submitted:—

1. That there is a reasonable prospect that the work can be accomplished, but that it would be improper to deny that it is attended with a certain amount of risk.

2. That this risk is limited to one contingency—viz., the possibility of sea water finding its way by some unforeseen fissure into the workings in quantity too great to be overcome. Apart from this risk, tunnelling in chalk is easy and rapid, and the execution of a tunnel of the length of the one under consideration is only a question of time and expense.

3. There seems to be no reason to assume that the tunnel would cost more than ten millions sterling, or that it could not be completed in nine or ten years.

4. The question of risk would be fully solved by sinking land shafts on each coast, and driving the preliminary driftways. This portion of the work being safely accomplished, the remainder would be of an ordinary character.

5. The possible loss would be measured by the cost of this preliminary work, which is estimated at one million and a half, and which could not exceed two millions, or (say) one-fifth of the whole cost of the tunnel.

6. That this risk should be undertaken by the Governments of France and England, if, after consideration, they deem the importance of the work and the probability of its completion sufficient to justify them in doing so.

Austin.

Towards the close of last year Mr. W. Austin proposed a submarine three-way tunnel under the Channel. His plan is to cross at a line of route extending from the landing piers at Folkestone to the landing piers of Cape Grisnez, but the tunnel will range below the sea bed, at a safe depth for practical permanent masonry arches, which will be constructed of imperishable materials, on an improved principle of vertebraical bond. The tunnel is intended to pass underneath the submerged island, called the Varne, laying near the mid-channel, and on which island Mr. Austin proposes to erect a central ventilating shaft or tower, which would be available as a permanent central lighthouse and naval signal shaft; also to afford a refuge or retreat for crews of ships wrecked in the Channel. As a fence or guard to this central tower or shaft, it is proposed to have two ranges of timber floating breakwaters, so as to act as floating retreats for ships, and protectors to the tower shaft from hurricanes or gales. Two other masonry shafts will be permanently constructed for ventilation and pumping purposes at each shore. Seven or eight temporary shafts will also be constructed in iron, and sunk and bored down to the tunnel arching, so as to give ventilation to workers in construction of the tunnels, and also to remove a portion of the excavated *debris*. These temporary shafts would be protected by moored floating booms or fences during the construction of the tunnel, and, on completion of the tunnel, the temporary shafts and booms would all be removed, having done their work. The gradients of inclines of the proposed tunnels are so arranged that the steepest gradients of the two shore inclines, or connections with the main land railways, in England and France, do not exceed 1 in 100, so that locomotives of moderate powers would accomplish the required work easily. Occasional openings are to be constructed in the masonry range of tunnel wall sides, so as to allow for a traverse of engines and carriages from one range of tunnel to another, in the event of any accident or emergency, when traverse frames would quickly shift the disabled carriages out of the way of an obstructed traffic.

Arrangements of a distinct and peculiar character were to be made for the proper ventilation of the tunnels, by air and water streams; also for the lighting the tunnels throughout, by perfected modes of gas burning, in specially constructed lamps, &c. Every facility will be provided for laying down a perfect system of telegraph conducting wires, which will be easily accessible for adjustment and repair; and the present great risks and accidents, now so often occurring, of tearing up telegraph cables by ship's anchors will then be avoided. Subways are to be constructed throughout the tunnel ranges, which will exhaust any accumulation of steam and waste waters, or temporary leakages, and which water will be passed through wellpits, and then ejected by pumps, connected with the great central shaft and two shore shafts. The advantages of three tunnel ranges will be to keep special, ordinary, and goods traffic trains separate and distinct, and thus obviate present causes of frequent accidents by clashing trains conveying passengers and goods on the same ranges.

Fowler.

Mr. John Fowler has for several years past directed his attention to the best mode of improving continental communication, and he prefers a system of ferrying the trains over in steam vessels rather than either a bridge or a tunnel. He has for the last two years associated with him Mr. Abernethy, and Mr. Wilson as acting engineer. After a careful examination of the harbours of Calais and Boulogne and the coast between them,

and after considering the general question, these gentlemen came to the conclusion that the following were essential requirements:—

1. Well-sheltered harbours with deep water on both coasts capable of affording ingress and egress at all times, irrespective of weather and tide.

2. A class of vessels, in the nature of ferry-steamers, of greater size and power, making rapid passages, and comparatively unaffected by wind and sea.

3. Safe and speedy means for the interchange of passenger traffic between the railways and such ferry-steamers, so as practically to form a continuous communication.

Conceiving that the harbour and pier at Dover afforded very inadequate terminal accommodation, and insufficient protection, particularly from easterly and south-easterly gales, they propose the construction of a new harbour westward of the existing pier, with a graving dock, a covered berth for the steamers, and hydraulic apparatus for transferring the trains from the quay to the steamers and *vice versa*. They consider that Calais, which was exposed to all winds from west to east, and was choked up with sand, offers no facility for a harbour for such steamers; and that the harbour of Boulogne, though more readily capable of partial improvement, partakes of the same natural defect of sand accumulation. They have, therefore, selected a point of the coast south of Cape Grisnez and north of Ambleteuse, near the village of Audresselles, where the deepest water was to be found near the coast, and sheltered from the northward and eastward by Cape Grisnez. They consider that, by constructing a harbour at this point, they will secure the shortest available sea passage, with clear navigation across the Channel from Dover, and with the advantage of the first-class light on Cape Grisnez as a guide on the darkest nights. They propose to connect this harbour by a railway four miles long with the Chemin de Fer du Nord, and to add a short branch for communication with Calais and the north.

The steam vessels the projectors of this scheme propose to employ between these harbours are to be 450ft. long, with 57ft. of beam, and 80ft. across the paddle-boxes, propelled by disconnected engines of 1,500-horse power, performing the voyage in one hour, and with comparatively little pitching or rolling in any state of the weather. They further propose to form covered stations for the interchange of passenger and goods traffic between the steamers and the shore, the transfer of the passenger carriages to be effected by hydraulic apparatus, irrespective of tide, in a few minutes. The steamers are to be luxuriously fitted up with first and second-class refreshment saloons, and with ladies' and private cabins; and, in addition to the saving of time in the sea passage, and on either coast, the passengers are to have the advantage of being able to secure and retain the seats in their railway carriages throughout the journey between London and Paris and other centres. At the same time the various saloons and cabins and the decks of the steamers will be at their service. The projectors believe that the extra comfort to the passengers afforded by such accommodation, and by the regularity of the service, is far more important than the saving of time that would be effected. They reject as insufficient and unsuited to the requirements of the present day, all partial improvements of Boulogne Harbour and the service between that harbour and Dover or Folkestone; and they estimate that these works, and the railway steam-ferry steamers, may be completed within three years, at an expenditure of £2,000,000.

REMINGTON.

In 1865 Mr. George Remington published a plan for the construction of a tunnel railway from Dungeness to Cape Grisnez. Before advancing his scheme Mr. Remington ascertained as far as possible the nature of the geological strata forming the bed of the Channel. He found that the coast in the neighbourhood of Dover and Folkestone consisted of chalk, which extends under the Channel to the Calais shore. As Mr. Remington concluded that this formation, which is in itself so very porous and contains so many fissures, could not be suited for tunnelling under a great head of water, he visited Dungeness, and examined the whole line of shore from Hastings to Dover, and satisfied himself that the Wealden formation, consisting of very strong clay, beds of freestone, and freshwater limestone, extended from Dungeness across the Channel to Cape Grisnez. Having concluded that that was the proper course for the construction of the tunnel, he at once proceeded to prepare plans and sections, and laid them before the Board of Trade, the Minister of Works, Paris, and others. This proposition has again been brought before the public within the last few months.

The line is intended to commence at the town of Lydd, where it will join the branch railway from the South-Eastern at Appledore. It will descend from Lydd at an inclination of 1 in 70, the distance of $3\frac{1}{2}$ miles to the point of Dungeness, where the level of the rails will be 240ft. below the level of low-water spring tides. The rails would then rise from Dungeness shaft at the rate of 1 in 3,795 for about 7 miles, and then fall at the rate of 1 in 1,200 for about 8 miles, to the centre shaft on the "Ridge;" from thence fall at the rate of 1 in 3,265 for 11 miles to Cape Grisnez, and then rise at the rate of 1 in 70 and 1 in 81 to join the French railways.

The height of the tunnel will be 30ft. from the soffit of the arch to the centre of the invert, and there will be a clear headway of 20ft. for the trains; the space between the rails and the invert will be occupied by a sewer, running along the centre line of the tunnel, and on each side of it two air tunnels, for the purpose of providing ventilation. The width of the tunnel will be 25ft., it will be constructed of brickwork and masonry, surrounded with concrete, and also a mass of concrete will be placed upon the invert surrounding the air and drainage tunnels, and forming a bedding for the sleepers of the railway.

There will be three main shafts of large dimensions. The centre shaft on the "Ridge" will be protected by a breakwater, formed of rubble and faced with ashlar. The other shafts are to be effected by means of wrought-iron tubular piles from 8ft. to 10ft. in diameter, the inside strengthened with plates on the cellular principle. These piles will be provided with valves to regulate the ingress and egress of water during the time of sinking into position, and when sunk they will be supported by proper guy chains and tackle from anchor moorings placed in various directions around the piles, every pile forming a shaft of sufficient length to reach the entire depth of water and through the bed of the Channel down to the level of the tunnel. It is intended to weight the lower end of the piles, and to sink them into position on the principle of the angler's float. The water will then be pumped out by steam power, and the soil be brought up from the interior and cast over on the outside, forming a cone round the pile. Mr. Remington estimates the cost of these works at £6,998,200.

MARSDEN.

Mr. Charles Marsden's scheme, which was brought before public notice in April last, consists of a tubular tunnel, made of boiler plate, and having a double skin, on the well-known principle used in shipbuilding, the annular space being filled in with artificial stone. Mr. Marsden proposes to carry pipes for ventilating the tunnel, as well as pipes for water, sewage, and telegraph wires, at the top of the tunnel. At the bottom runs the line of road, on which the railway is laid. The ventilating pipes are formed with longitudinal slots. Air is to be forced from the shore end into these tubes, which will pass through the slots into the tunnel, and ventilate it. Mr. Marsden has a special plan for jointing the several lengths of the tube. It consists in fitting one end of the tube with a series of stepped or curved plates, which are secured in place by screws or rivets. The adjoining end of the next pipe is fitted with a bulge or socket. Another series of plates is employed, one end of which is forced under the open end of the stepped plates. They are prevented from falling out by being guided into position by a number of rings, fitted on the end of the pipe. Another ring is employed on the outside, to hold the plates. A portion of this ring is looped or pocketed, to enable the plates to be placed in position. When passed through this looped portion they are made to slide round in succession, so as to meet each other, until the whole diameter of the pipe end is covered. They are then firmly secured in place by keys being driven in between them and the ring. The loop is then filled in with a wedge-piece, and thus the whole joint is made sound, flexible, and tight. The joint being flexible admits of its adapting itself to the general contour of the bed of the Channel, and following any undulation caused by a settlement of the soil.

It is proposed to lay this tunnel in the following manner:—A cutting is first to be made on land about two or three miles in length, gradually descending to a point where the water is about ten fathoms deep. A sea wall is to be built about 50ft. from the water's edge. A portion of a cylinder is to be built in the wall and made water-tight, and the sea is then to be allowed to flow up to the wall, so that the next cylinder can be floated and placed in a proper line. The same with the next, and so on, lowering them from a raft, which they will form. Mr. Marsden proposes that divers should cut through moderately high projections in the Channel bed, and also the levels, making a trough, into which would be lowered clay, the divers puddling the same, and thus forming a bed for tubes to rest upon. The cylinders can be made on the coast, and, when finished, have their ends stopped and be towed to the spot required, half filled with the artificial stone composition. Four or six of the tubes can be used to form a raft or stage to carry the machinery for lowering and fixing the tube in place, and afterwards can be used on the land end to finish the connection on shore. By this means Mr. Marsden estimates a working tunnel could be completed in about four years, without the danger of its being flooded. The heading at each end is to be made in three or more parts, and well secured with india-rubber, or other packing, and screw bolts. The heading, after two or three cylinders are fixed together from the outside, is to be removed from the inside, making an entrance from the shore end into the next tube, and so on throughout. The double cylinder is braced to keep the inner from the outer. The space between the two, which is 5ft. or 6ft., is to be filled with tarred granite and asphalte, which will form a perfect wall. As Mr. Marsden considers it impossible to have a ventilating shaft in the Channel, he proposes to have machinery on each shore to abstract the vapours from, and also to force air into, the tunnel. Mr. Marsden's estimate for a tunnel between England and France on his principle is £12,260,000.

MACHINERY FOR SHAKING STRAW.

MR. JOHN WILSON, of Poppleton, York, has patented some improvements in machinery for shaking straw. His invention consists of novel arrangements for agitating the sifter or riddle and giving it a reciprocating or rocking motion necessary for the falling of the grain on to the delivering board. The shaker consists of a series of leather bands (with spaces between each) and cross bands attached to bars at each end of the machine, and extending from the feeding hopper and drum to the delivering board. It is actuated by two hangers or rods suspended vertically within each side of the machine by means of pivots. These hangers are attached to iron shoes, which contain grooves in which a shaft works provided with an eccentric at each end. The shoes being attached to the delivering board, the revolution of the eccentrics gives an oscillating motion to the shoes, hangers, and board, and also to the leather shaker, alternately slackening and tightening each end, the shaker being supported midway from the board by uprights, leaving two divisions of the shaker in a slack position while the machine is at rest.

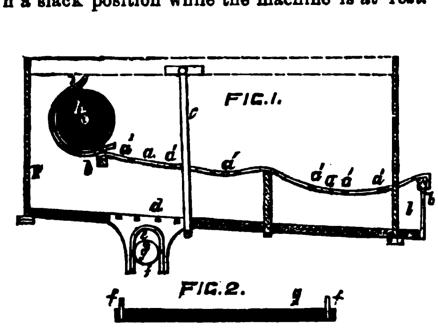

Fig. 1 in the annexed cut shows an internal side view of the shaker, and fig. 2 a longitudinal view of the spindle and eccentric bosses, which actuate the shaker *a a*, fig. 1, which is formed of a series of leather bands placed side by side, having cross bands at $a^1\ a^1$. The ends of the shaker are attached to bars *b b*. *c* is one of the hangers, of which there are two, one on each side of the machine or interior of the thrasher. Each of them is fastened to shoes, one of which is shown at *d*, in which a socket *e* is formed to receive the eccentric boss *f* on the spindle or working shaft *g*, fig. 2. The revolution of the spindle causes an oscillating or rocking motion of the shaker at the centre, alternately tightening and slackening each side or semi-surface, and thereby effectually shaking the straw. *h* is the drum, and *i* the hopper, into which the straw is fed; *k k* are the wooden hangers, and *l* part of the framework.

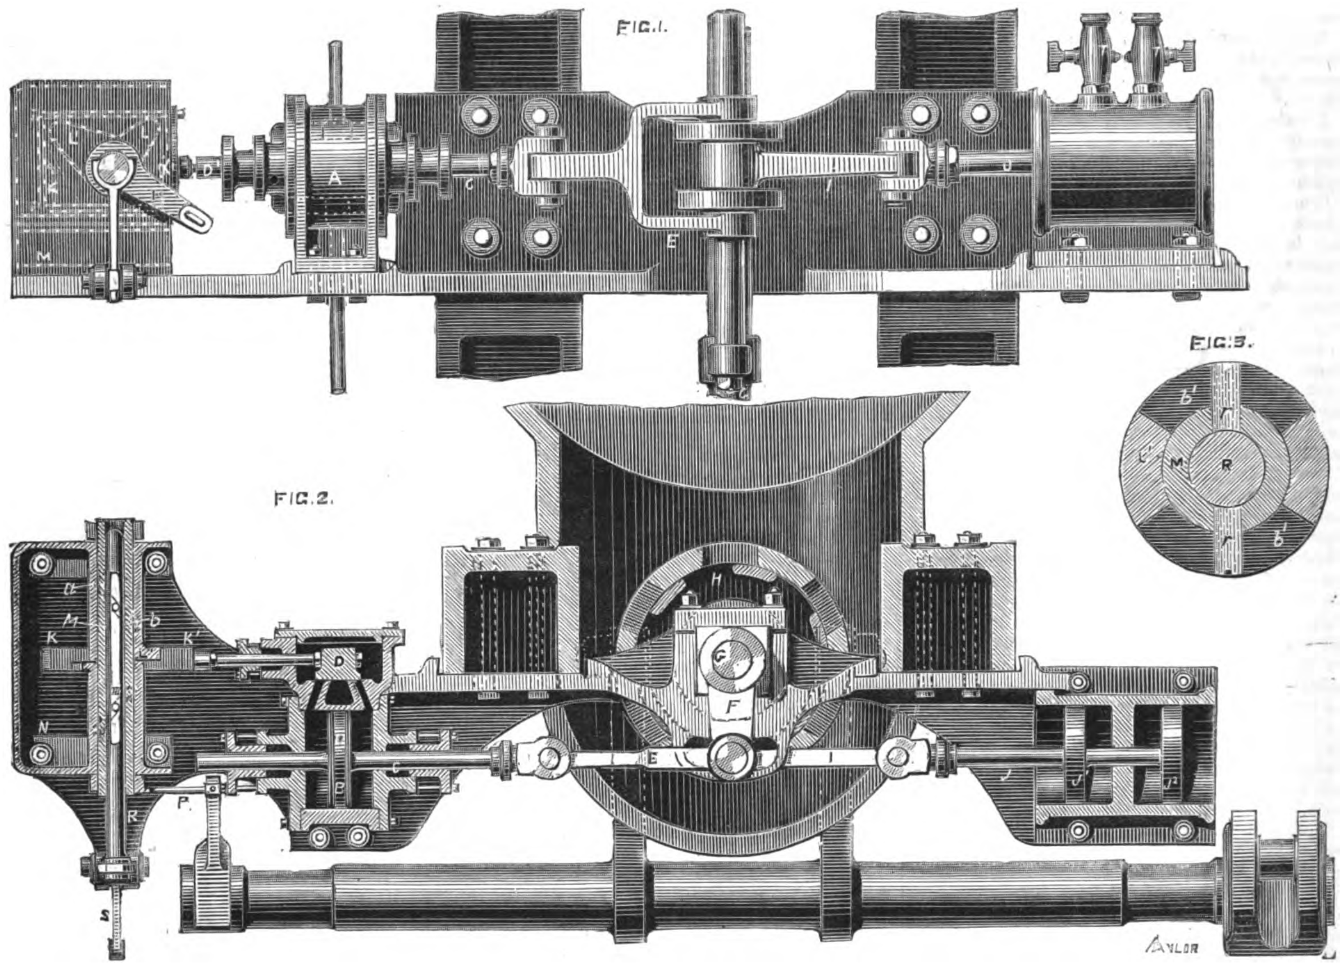
IMPROVED METHOD OF WORKING CUT-OFF VALVES.

BY MESSRS. JOHN WOOD AND CO.



WORKING CUT-OFF VALVES.

MESSRS. JOHN WOOD and Co., of Sowerby Bridge, Yorkshire, have patented some improvements in cut-off valves. The improvements consist in the application of a separate small steam cylinder and piston with ordinary slide valve. The piston rod is connected with another rod in communication with and giving motion to the spindle of the cut-off valve. The accompanying engraving shows at fig. 1 an elevation, and at fig. 2 a plan of these improved arrangements; fig. 3 being an enlarged section on the line *a b*, fig. 2. A is the small steam cylinder with its piston B and rod C, and D is an ordinary slide valve. The piston-rod C is connected with a rod E attached to a lever arm F fixed on the spindle G of an ordinary piston valve H, and to this arm F is another rod I, connected to a piston-rod J, on which are two pistons J^1 and J^2 in a double cylinder open at the ends, forming air cushions. The spindle D^1 of the slide valve D is connected to a rectangular frame, on the two opposite sides of which are formed shoulders K and K^1. Within this frame are two cams L and L^1, mounted upon a hollow spindle M, supported in bearings of a frame N. On one end of the hollow spindle M is fixed a lever arm P, which may be connected by a rod to a lever on the ordinary rocking shaft (by which the slide motion of piston valve is obtained), or this rod may be connected to an eccentric on the flywheel shaft or other convenient part of the engine. R is the slideable rod fitting within the hollow spindle so as to be capable of sliding or being moved endwise by the action of the governors upon the bell-crank lever S. On this rod are two pins *r*, which pass through slot holes *m* in the hollow spindle, which slot holes are parallel with the axis thereof, and these pins also enter slot holes *l* and l^1 in the bosses of the cams L and L^1, which slot holes are oblique to the axis thereof.

It will be readily seen that any variation of the speed of the engine will be communicated to the slide-rod K, which will act upon the cams L, turning them right or left upon the hollow spindle, so that the rocking motion given thereto by the lever arm P may cause them to actuate the slide valve D accordingly, thus admitting steam to either one or the other side of the piston B, which being moved will operate the lever F, and consequently the piston valve H, causing the steam to be cut off sooner or later, as required. To prevent concussion of the piston B against the ends of the steam cylinder the cylinder and pistons J and J^1, which form air cushions, are provided, the air being admitted through taps T, which may be regulated to admit more or less, as required. This apparatus may be worked by either steam, air, water, gas, or vacuum, and it is equally applicable to slide valves and to all classes of engines wherein cut-off valves are used.

IMPROVED BICYCLE VELOCIPEDE.

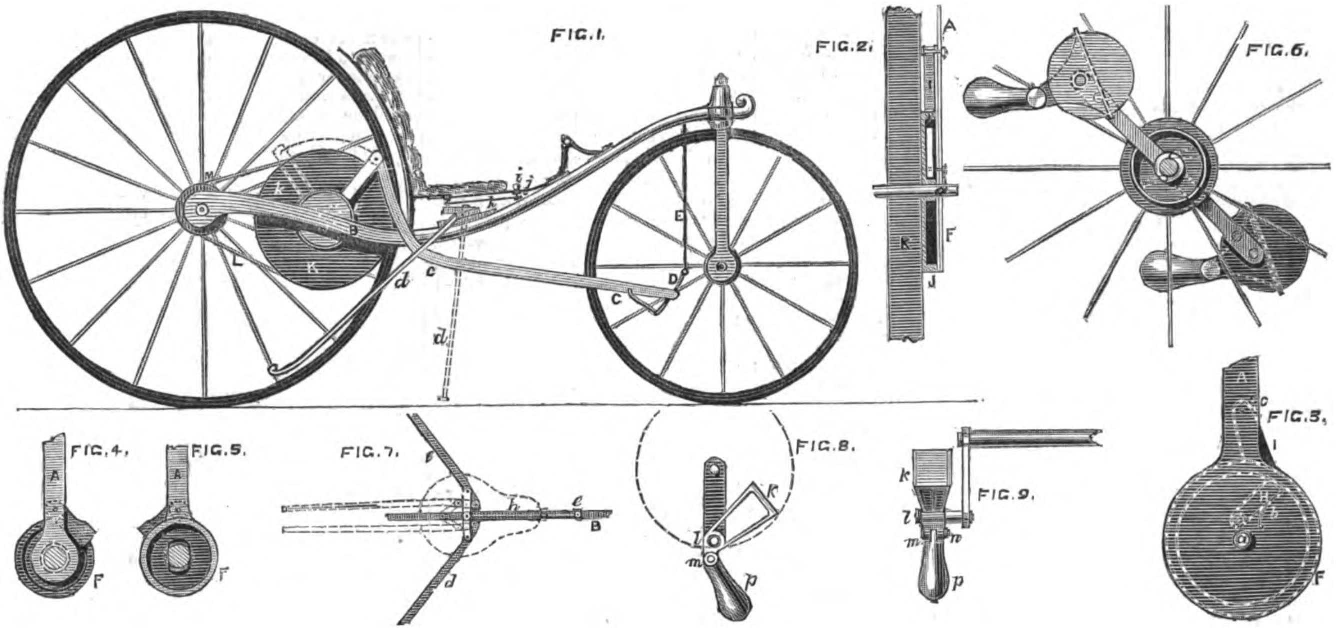
THE employment of lever power to the driving wheel of velocipedes forms the subject of a patent which has been secured by Mr. W. W. Hooper, of Bow, and Mr. J. D. Hooper, of Millwall, through the agency of Messrs. Robertson, Brooman, and Co., of 166, Fleet-street. The inventors connect a lever with the axle of the driving wheel, or to a wheel so placed that it may be connected with the driving wheel to multiply its revolutions. The lever is made to act on the wheel with which it is connected by means of a pawl furnished with lugs or claws, which impinge against or grip a flange on the wheel axle in one course of their stroke, and are released on their return stroke. Springs are employed in connection with the levers and pawls, to ensure their proper working. Fig. 1 of the accompanying engraving is an elevation of a bicycle velocipede. A is a lever, of which there are two, one on each side of the beam B; these are connected to the treadles C C, which are depressed alternately by the feet of the operator. The ends of the treadles C are connected to stirrup or foot-plates D by pins; the upper ends of the foot-plates and the forward ends of the treadles are held by a rod or wire E fastened to the beam B. The lever A is attached to a ring or disc F working on a stud *a* fixed to the beam; the disc F carries two pawls or claws H I, as shown more clearly in the detached sectional and face views in figs. 2 and 3. These pawls are brought into action on the forward movement of the levers A by jambing the ring of the wheel or disc K, which is mounted loosely on the same stud. The outer edge of this wheel K is grooved for the band or chain L to run in, and by which the rotary motion of the disc K is communicated to the driving wheel M. There are springs *b c* on the pawls to keep them always bearing against the faces of the ring J.

In some cases, the inventors employ a single pawl of the form shown in fig. 4. This pawl has two lugs on it, so that as the lever A is moved in one direction, the lugs grip the ring F, propel the vehicle, and in the reverse movement the lugs slide over the ring without gripping it. Fig. 5 is a similar view to fig. 4, but in this action the lever has a slight rising and falling movement imparted to it, so as to lift the pawl and cause the lugs to grip the ring more firmly. Fig. 6 is a view of the central portion of a wheel with the pawls and foot-plates fitted to act upon a ring on the nave itself. The invention consists, in the second place, in supporting and preserving the equilibrium of the vehicle by means of movable arms or struts attached in such a way that they may be readily extended to either side. This is effected by jointing to the beam B two legs or rods *d e*, as shown in fig. 1 and in plan in fig. 7; these legs are likewise jointed to links *f g*, by which the necessary motion is imparted to them by means of a rod or bar *h* moved by the operator when he wishes to get on or off the vehicle. The handle or knob *i*, by which the bar is moved, is fitted in a slotted guide *j* to ensure the legs working in the proper manner. When the knob is moved towards the front of the vehicle, the legs are caused to spread outwards and occupy the positions indicated in full lines in fig. 6, and when the knob is drawn back, as in fig. 1, the legs fold in towards the wheels as shown.

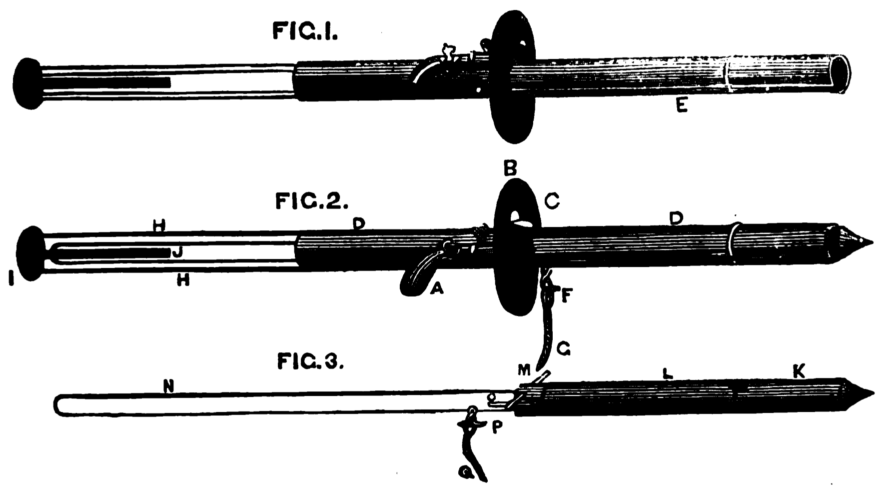
This invention further consists in providing the cranked portion of the driving wheel or wheels of ordinary velocipedes with foot-plates at a distance above them, whereby wheels of larger diameter than usual can be employed. Fig. 8 is a side view of a foot-plate *k*; it is attached at its lower part to the crank pin *l*, as shown in fig. 9. Below the crank pin and connected to the plate are two cheeks *m n*, through which a bolt passes, and which supports a balance weight *p*; a nut on the end of the bolt can be screwed up or loosened in order to adjust the weight *p* at any inclination to the foot-plate.

IMPROVED BICYCLE VELOCIPEDE.

BY MR. W. W. HOOPER AND MR. J. D. HOOPER.



THE ROCKET HARPOON GUN.



THE ROCKET HARPOON GUN.

THE gun represented in the annexed engraving has been employed for some years in the whale fishery round Iceland with great success—forty-six whales having been captured by two small steamers, cruising off the coast of Iceland, in the course of two months during the summer of 1866, and forty, during a like period. in 1867. These whales belonged to a class known as the "Sulphur bottom," and are admittedly the most difficult to capture, and such as ordinary whalemen think it useless to attempt to take. The inventor of this gun was for many years one of the most successful and experienced whaling captains sailing from America; and the present efficiency of the weapon has been attained only after many years of labour and experiment, and after having been practically tested in connection with several whaling expeditions from New Bedford, U.S. It possesses many advantages over the old method of whaling; and this one especially, that the rocket harpoon, with line attached, being fired from a gun poised on the shoulder, kills the whale almost instantaneously—the rocket, by means of a ten-second fuse, firing a shell which explodes on penetration.

In our engraving, fig. 1 represents the gun; fig. 2, the gun and rocket harpoon; and fig. 3, the rocket harpoon. In fig. 2, A is the pistol, which ignites the rocket; B is the protecting disc, through the opening in which, C, the marksman takes aim. This jointed cover or flap C is folded down during the time of taking aim, but on firing, the action of the back fire of the rocket immediately closes it, thus protecting the eyes of the marksman; D, the metal tube of the gun, through which, as in fig. 1, marked E, will be seen a slot or opening underneath, for the linked hook F, attached to harpoon, to escape with the rope G; H, the four parallel rods, of about 10in. in length; I is the disc against which the back fire of the rocket acts, escaping through between the bars; J are rods attached to disc to keep the harpoon in position. In fig. 3, K is the shell, on the rear end of which is screwed L, the rocket; M, the barbs on harpoon N; two are open showing how they act when the strain is on, the others are closed as in O, their position on penetration; P, the link on harpoon, with rope attached, Q. Weight of gun and harpoon, 30lbs.; charge in shell, 1lb.; charge in rocket, 2lbs.

In the use of bombs and other explosive projectiles, as heretofore used, the great objection has been the laceration of flesh, and the consequent weakening of the hold of the barbs of the harpoon on the whale; but in the use of this weapon no such objection can be made, from the fact that the rocket carries the harpoon with sufficient force right into the body of the whale, where the shell explodes, causing death. The laceration of flesh is only in the immediate neighbourhood of the bomb, and some distance apart is the barbed part of the harpoon. As soon as a strain is brought to bear on the harpoon, the barbs open and retain a secure hold by getting imbedded in the tough integuments of the hide, together with the blubber, through which the weapon has penetrated. In every case the barbs would break before allowing the harpoon to "draw out."

In the class of whaling in which this gun has been used, the whales had to be hauled up from the bottom, sinking when dead; and, although the rope was adapted to bear a strain of three and a half tons, there was never occasion to attribute the loss of a whale to the "drawing out" of the harpoon—either rope or barbs being sure to give way before such a thing could happen. The bomb is not explosive on contact, the rocket, by means of a ten-second fuse, igniting it. The composition employed in the manufacture of the rocket is of a peculi kind, and has been exactly graduated, after man experiments, to the distance which it is required carry, say from seventy to ninety feet. The agen for this gun is Mr. W. O. A. Lowe, of 9, North John-street, Liverpool.

LONDON ASSOCIATION OF FOREMEN ENGINEERS.

ON Saturday, the 16th inst., the members an friends of this institution, to the extent of ove 150 in number, paid a visit of inspection to the Abbey Mills Pumping Station of the great Main Drainage Works, West Ham. The day was not all that could have been desired for such a purpose, for at the time arranged for the arrival of the party rain fell freely and the wind swept over Plaistow Marshes in fitful gusts. Foremen Engineers, however, are, as a rule, not easily diverted from the realisation of a fixed purpose, and on this occasion, they were not deterred from it by adverse meteorological influences.

At the entrance gate of the high and middle level sewers, which cross the Stratford-road immediately beyond Stratford Bridge, the Associated Foremen, headed by their president, Mr. J. Newton, and accompanied by Mr. Richard Moreland, Mr. W. Todd, and several other engineering employers, were met at half-past three by Mr. G. Usher, resident superintendent engineer of the Abbey Mills Station. Passing along the grass-covered embankment through which the sewage tunnels at this point are laid, an excellent view was obtained of the magnificent engine-house and its appurtenances, which are on the south-west side of the embankment. The two chimney shafts, each 209ft. in height and standing isolated on either side the building, appeared like sentinels constantly on

guard. These stately columns are externally octagonal in form, and are capped by ornamental iron roofs, pierced for the egress of smoke. The engine and boiler houses form one building, the style of architecture being mixed. The decorations, which are very elaborate, consist of coloured bricks, encaustic tiles, and stone dressings, floriated carving being introduced at the caps of piers, columns, and pilasters. A cupola or dome of a highly ornamental character surmounts the engine house, its topmost point being 110ft. above the floor line. It must be admitted that the effect of the whole of the exterior of the building is imposing in the extreme, and one only regrets that the locality in which it is placed is comparatively an unfrequented one. The structure is apparently "born to blush unseen," whatever may be said of its "wasting its 'sweetness' on the desert air." On entering the building, on Saturday, a number of drawings on a large scale, and illustrative of the arrangements of the station, were found on the walls of what now seems a vestibule, but which is designed for a workshop, and these were clearly explained by Mr. Usher. Right and left of the vestibule and reached by descending staircases of iron are the stoking floors, in front of the boilers, of which there are in all sixteen, in two series of eight each. The disposition of the boiler houses is in all respects admirable, and tramways for the conveyance of coal, by trucks, from the vaults to the furnaces make the fitments complete. On ascending, the party was at once introduced into the engine house, where the scene was striking in the extreme. The height of the building, the rich elaboration of all its details, its cruciform shape, and the colossal and gorgeously fitted up engines within it, tended to convey the idea that it was a temple consecrated to the genius of science rather than an ordinary place of shelter for steam engines.

It is impossible, without occupying too much space, to describe minutely the grandeur of the interior of the building, and no other word than "grandeur" will convey an impression of its beauty. The engines are eight in number, and are each of 142 horse power. They are disposed in pairs, and in such a manner that the eight steam cylinders stand round the centre of the edifice under the dome, from which the engines themselves are lighted. By this plan the visitor has an opportunity of surveying the mechanical excellence and peculiarities of the giant motors, which are the work of Messrs. Rothwell and Co., of Bolton, Lancashire. On the occasion of the Foremen's visit the whole of the engines were put to work simultaneously, by direction of Mr. Bazalgette, who was unfortunately prevented by illness from attending in person, and the effect was one which will not be easily forgotten. Subsequently, the visitors ranged over the establishment and left no accessible portion unexplored. For Mr. Usher it is but justice to say they found a most intelligent and valuable guide, ready at all times to answer questions, and untiring in his efforts to satisfy inquirers. Under these circumstances, as may be imagined, the inspection was of a kind most instructive and gratifying to the inspectors. Two hours were spent in unravelling the mysteries of the Abbey Mills Station, the gigantic pumps of which place lift the sewage of districts covering an area of 25 miles a height of 36ft., and whence it flows to the outfall at Barking.

At the termination of the visit some seventy of the visitors adjourned to the Royal Hotel in the Bow Road, where a collation was provided for them. Mr. J. Newton presided at the festive board, and was supported by Messrs. Moreland, W. Todd, J. Timme, J. Campbell, W. Newton (of the Metropolitan Board of Works), G. Usher, Captain Rintoul, and others. The Chairman, in proposing as a toast the "Metropolitan Board of Works," took an opportunity of expressing the gratitude of the Association for the kindness shown to it on this occasion, and spoke eulogistically of Messrs. Bazalgette and Cooper. Mr. W. Newton responded in an eloquent manner, and justified the large expenditure of money by the Board of Works in erecting the Abbey Mills Station. "The Engineering Staff of the Board of Works" was next given from the chair, and to this Mr. Usher replied. For "The London Employers of Engineering Labour" Mr. Moreland admirably responded, and for "The Association of Foremen Engineers" its President answered. The whole of the proceedings were of an interesting and pleasant character, and certainly this, the first excursion of the Association, was in all ways a marked success. No doubt it is the happy prelude to many other excursions of a similar nature.

Accounts are given of the healing properties of a new oil, which is made from the yolks of eggs, and is said to be much employed by the German colonists of South Russia as a means of curing cuts, bruises, scratches, &c. The eggs are boiled hard, the yolks removed and crushed, and then placed over a fire and stirred carefully till the whole substance is on the point of catching fire, when the oil separates and may be poured off. Hen-eggs are considered the best, and nearly two tea-spoonfuls of oil may be gained from a single yolk.

MANCHESTER STEAM USERS' ASSOCIATION.

The last ordinary monthly meeting of the executive committee of this Association was held at the offices, 41, Corporation-street, Manchester, on Tuesday, September 28, 1869, Mr. Hugh Mason, of Ashton-under-Lyne, vice-president, in the chair, when Mr. L. E. Fletcher, chief engineer, presented his report, which on that occasion was for two months, and is given in abstract as follows:—During the past two months, 455 visits of inspection have been made, and 995 boilers examined, 643 externally, 5 internally, 20 in the flues, and 327 entirely, while, in addition, 8 new boilers have been tested by hydraulic pressure. In these boilers 147 defects have been discovered, 22 of them being dangerous. Furnaces out of shape, 5; fractures, 28; blistered plates, 12—1 dangerous; internal corrosion, 13—4 dangerous; external ditto, 23—8 dangerous; internal grooving, 8; external ditto, 2; feed apparatus out of order, 2—dangerous; water gauges ditto, 13; blow-out apparatus ditto, 1; safety valves ditto, 8—6 dangerous; pressure gauges ditto, 8; boilers without glass water gauges, 8; without feed back pressure valves, 15; cases of deficiency of water, 1—dangerous.

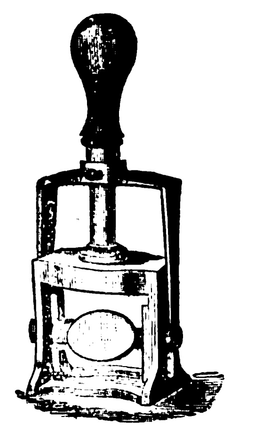
On the present occasion I have to report the occurrence of 6 explosions, by which 6 persons were killed and 4 others injured. Not one of the boilers in question was under the charge of this Association. The scene of the catastrophe has been visited by the officers of this Association in five of these cases, and particulars of the exploded boilers carefully taken, while information with regard to the other explosion has been obtained by an engineer residing on the spot. All the explosions referred to resulted, as usual, from the simplest causes, four of them being due to bad boiler making, and the fifth to defective condition and bad boiler making combined, while all of them would have been prevented by competent inspection. In addition to the above, an explosion, by which one man was killed, occurred on July 19 last, but of which information was not received until after the last monthly return was made up.

A fatal case of scalding may also be referred to, which occurred in a somewhat remarkable manner. The driver of a colliery locomotive engine was letting a train, consisting of some ten or twelve coal waggons, down an incline, the train being in front of the engine. These waggons had to pass under a roadway bridge, which, though affording sufficient headway for them, did not do so for the engine, so that the driver should have pulled up before arriving at this bridge. The brakes, however, were overcome by the steepness of the incline, and, notwithstanding that the driver reversed his engine, the train ran on, passing under the bridge, and dragging the engine after it. A collision consequently occurred, when the dome was swept off from the top of the boiler, and blown by the rush of steam and hot water to a considerable height, while, at the same time, the driver was so seriously scalded that he died a day or two afterwards. Literally speaking, this was a steam boiler explosion, as the boiler was rent, and steam and water rushed out with considerable violence and force. Since, however, the explosion was not due to any defect in the boiler, but arose from extraneous circumstances, it has not been thought desirable to insert it in the ordinary list of boiler explosions. The following is a statement of explosions from July 24, 1869, to September 24, 1869, inclusive:—August 11, multitubular marine (internally fired), 3 killed; August 16, single-flued or Cornish (internally fired); September 1, vertical (internally fired), 1 injured; September 3, two-flued or Lancashire (internally fired), 1 killed and 1 injured; September 8, single-flued or Cornish (internally fired), 1 killed and 1 injured; September 16, breeches (internally fired), 1 killed and 1 injured; total, 6 killed and 4 injured.

An announcement made by Messrs. Horne, as agents of the directors of the Services Maritimes des Messageries Imperiales, seems to discountenance the doubts recently expressed as to the Suez Canal being immediately ready for general traffic. They notify that the steamship "Godavery" will be despatched from Marseilles on November 10 to Port Said, where she is expected to arrive on the eve of the inauguration of the canal. After the opening ceremony she will pass through the canal and continue her voyage direct to Calcutta. The "Godavery's" extreme length is 93 metres. Her tonnage (English) is 1,380 gross and 965 registered, and her draught with full cargo is 5 metres 41 centimetres.

THE TELEGRAPH ENDORSING STAMP.

The annexed cut illustrates a very simple but valuable machine for endorsing documents, such as bills of exchange, bank cheques, &c., &c. It is so arranged that the dates can be removed, thereby making it invaluable for all purposes of endorsement. It operates with perfect cleanliness, and is stated to be capable of producing 5,000 impressions per hour without applying fresh ink or the use of separate ink pads. The advantages which this machine possesses over others are varied and essential. First, the spring is enclosed in a cylinder in the handle and cannot by any possibility become loose or disarranged. Second, the piston, instead of being a solid body, is a hollow tube so connected with the pad as to act as a reservoir for the purpose



f supplying the ink to the pads, thus obviating the n clean necessity of constantly supplying ink, as the e servoir contains sufficient for fourteen days' consumption. Third, it possesses a thumb-screw which acts as a lock instead of the cumbrous lever of other machines, as the lever from its protrusion is always in the way and therefore objectionable. This invaluable machine is manufactured by Mr. H. B Sale, of 65, Constitution-hill, Birmingham.

ON THE MONCRIEFF SYSTEM OF WORKING ARTILLERY AS APPLIED TO COAST DEFENCE.

By Captain Moncrieff.

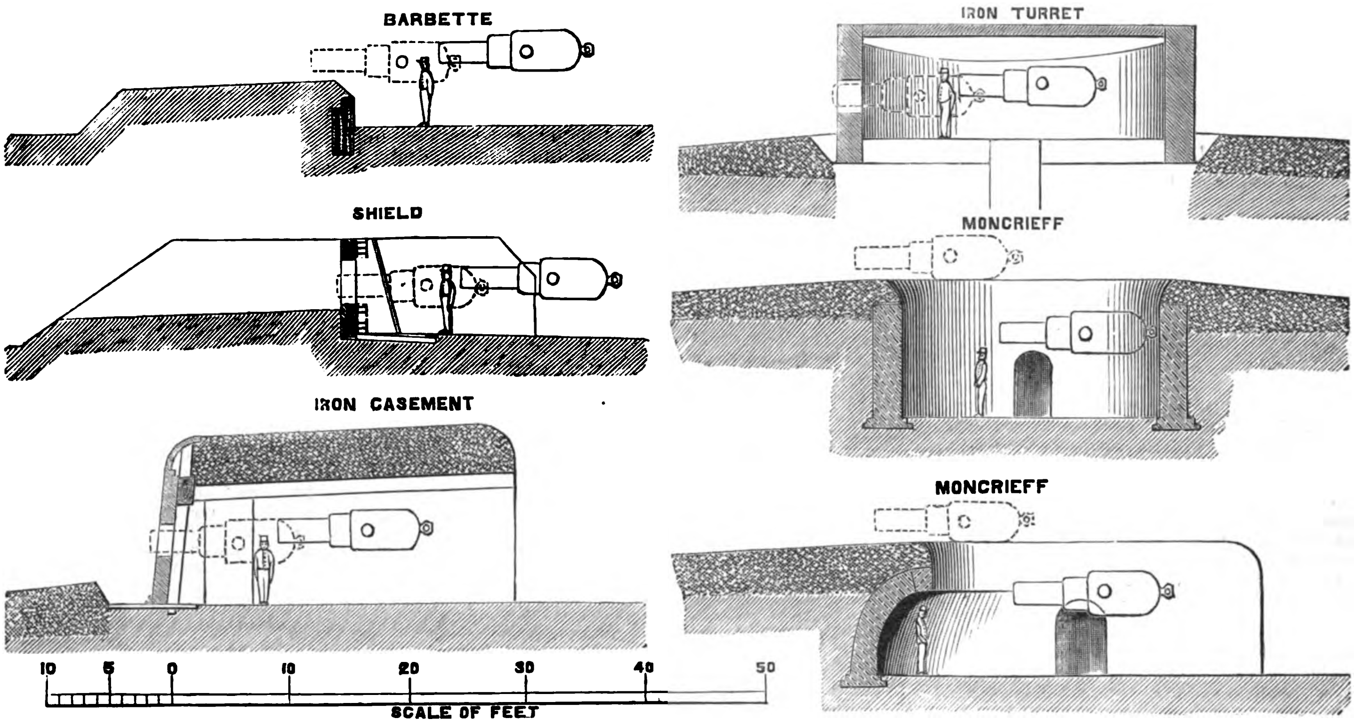
(Concluded from page 279.)

The second part of the system, viz., the profile of the batteries, is of the highest importance, because unless it is attended to great advantages are lost. This, unfortunately, makes the system extremely difficult of adaptation to existing works. In order to get the full advantage of it no exterior slope of parapet should be exposed to the view of the enemy. This prevents him from being able to tell whether the fire be correct or wasted, and affords no means to him of correcting error. The battery in fact is masked; so that at some distance, or in dull weather, a moving ship would have considerable difficulty in laying her guns on one battery, and still more difficulty if there were several batteries judiciously placed for the purpose of deceiving the eye. It can easily be understood that the slightest error in elevation would either carry the shot harmlessly over the battery or else cause it to ricochet off the glacis or superior slope. In fact, when the gun is down the enemy has nothing to aim at but an undefined horizontal line. In connection with this I should mention a very interesting fact, brought out by General Simmons at the last discussion of the Royal Engineers on a paper of mine. He stated that on analyzing the range reports of the Armstrong and Whitworth competitive trials, which were very carefully conducted, he found that the mean horizontal and vertical errors were very different. The horizontal error increased almost directly as the range, that is to say, at 400 yards it was four times as great as at 100 yards, but that the vertical error went on in a rapidly increasing progression, showing that it would be much more difficult to hit a low object than a high one of the same area. This law has an important bearing on the subject, and should not be lost sight of in designing defensive works of any kind. It will be observed that the interior slope of the parapet gives the most complete protection to the men, especially when the dome-form is adopted.

Up to the present time the new system has only been considered as an improvement, and its value has only been estimated as an adaptation to existing forts, and there are no proposals for applying it *per se*. I am extremely anxious to impress on you and on my countrymen that its full value cannot be seen in this manner, and that it suffers injustice by being thus treated. I trust its proper use will be fully discovered before the inevitable lesson is dictated by war, and that it may be applied in

ON THE MONCRIEFF SYSTEM OF WORKING ARTILLERY AS APPLIED TO COAST DEFENCE.

EXAMPLES OF FIVE METHODS OF MOUNTING HEAVY COAST ARTILLERY.



works expressly designed for it, and not merely adapted to its use.

The third part of this system consists in its application to given positions, the disposition of the batteries, and methods of working them in concert with or in support of each other. If I might be excused for using the paradox, the system for coast defence consists in the absence of any defined system; that is to say, instead of making large regular forts, and forcing surrounding circumstances into harmony with them, every accident of the ground in this case would be seized, where available, and small batteries, consisting of a few guns, or even one powerful gun, laid down so as not to take away the natural aspect of the position. These batteries would be well retired from the channel, and placed so as to support each other in case of attack, and should, when circumstances permit, afford flank defence to each other, in conjunction with obstacles of any character that could be conveniently employed, and with strongholds for infantry and light artillery, commanding, if possible, the sea-batteries, so as to make them untenable by an enemy, and so placed as to be in the best position for a reserve, ready to support any point attacked; the whole connected with good and sheltered roads. In stopping the passage of a navigable river or channel, for instance, the guns, instead of being massed, would be scattered round the points where marine obstructions were placed. These guns would be disposed in such a manner as to retain as much as possible for the defence the advantages of a free lateral range, converging fire, and different amounts of command. In other words, the method consists in placing in position the heaviest and most powerful artillery to the greatest advantage, making that the first consideration, and afterwards protecting the batteries, by separate and distinct arrangements easily devised by officers on the spot, against assault by any force that ships might land for that purpose.

When an object is to be attained I prefer to grapple with the most difficult and important part of it first,—do that well,—and meet the other requirements afterwards, with as little loss of efficiency as possible. The first object of coast defence is to meet and defeat the attack of powerful ships; the next is to protect the shore batteries against landing parties. It must not, however, be forgotten that there are positions of such importance that they might be attacked by an army on land. Such positions must either be defended by another army placed in a favourable position by such arrangements as those above referred to, or else by regular and complete earthworks thrown up in time of danger, which would enable a still smaller garrison to resist anything but regular approaches. There are, however, few coast positions of such importance as to draw the attack of a whole army; and such positions, as a rule, are now provided with regular works of a very high order; whereas there are many positions exposed to a heavy naval attack, such as our large mercantile ports, &c. They are almost invariably centres of population, who require only fieldworks and good small arms (which are now more powerful than ever) to repel the most determined attacks of any numbers that war ships could land.

I believe many of the present coast works are defensible only against a *coup de main*. Wherever land attack is of more importance than naval, the character and efficiency of sea batteries must give precedence to those considerations which provide against assault. On the best provisions for meeting this I do not pretend to give an opinion. In such cases, the possibility of attack by both direct and vertical fire must be kept in view. Where my system is employed for arming such works, one or two precautions would increase the power of resistance. 1st. The large guns for operating against ships, with traverses and parados to each, should be kept as far apart as space will admit. 2nd. Ample and thoroughly complete bomb-proof cover for the whole garrison should, if possible, be supplied in the middle of the work, with arrangements for interior defence (not barracks, but places for emergency), thoroughly secure from vertical fire—good and healthy barracks for the men being made independent of the works, and by preference kept out of the way. 3rd. Howitzers and light artillery ought to be kept in reserve, in bomb proofs constructed for the purpose, and (with the new system this can easily be done) also with the means of changing these to any required face.

The dispositions of defensive batteries such as those I have very imperfectly attempted to describe would not be complete without good arrangements for internal communications, not only by roads but by telegraph, with a clearly laid down and simple method of working them; that is, not liable easily to go wrong, nor to lead to mistakes, and which would not require very high skill. Such arrangements would increase the power of the defence, and indeed would be necessary with the detached system. I have accordingly given them some attention, and designed a general plan of laying off the ranges and working the telegraphs, which will make it possible to supply simultaneous information. The system I refer to (which has been submitted to the Director-General of Ordnance) would apply to any position, but its particular application would vary in each case. It is extremely simple. One part of it depends on electrical instruments which I have invented for the purpose, and which, without calculations or experience, give the range and positions of an indicated ship at every gun in the position. Another part of it enables the officer directing the defence to deliver in one instant, by the touch of his finger, a converging volley from one or both sides of a channel on a vessel sailing past.

The possibility of delivering correct fire in this manner on a moving object, without aiming, and by an officer not even in the battery, was illustrated in one of my experiments with the 7-ton gun-carriage at Shoeburyness; and I trust I may be given some day a chance of showing to what perfection this system can be carried. Methods of determining the distanc of vessels from batteries are practised here and in some continental countries. My method is designed to be quicker, simpler, and, therefore, more effective. It is adapted to work in conjunction with the arrangements for submarine mines. That part of it which gives the required information for sighting the guns is of so simple a character that the most uneducated gunner cannot make a mistake in its application. There are many other features of the system besides those I have particularly referred to which I shall not now discuss; each requires different treatment. Among these there are methods of mounting guns in ships, in floating batteries, Moncrieff carriages for heavy guns of position, adapted for locomotion, for coast defence, siege carriages, &c.

I may remark in passing that some of these applications are considered by officers of eminence to be quite as important as the class of Moncrieff carriages best known. For instance, I take the liberty of quoting from a letter I received from Colonel Brialmont, the great Belgian engineer and military writer, in November, 1868. He says: —"I am at present engaged in publishing a great work on fortifications. I shall naturally speak of your invention in it, and if agreeable to you I shall likewise mention your proposal with regard to *barbette* system in batteries of attack. I believe this idea is designed to have a great future. This last invention will perhaps bring you less renown than the one you have experimented on at Shoeburyness, but it will have a more general and easier application." I am most anxious to impress the national importance of this question of coast defence in relation to the system of earthworks which are now possible.

The day has gone by when the general principles of any science need be considered a mystery, and I submit that any man of intelligence, without knowing all those details which are the particular business of officers trained to apply them, may, nevertheless, form valuable opinions on the general principles of coast defence, and may, with care and observation, be able to arrive at sound conclusions regarding them. The security of a country like this does not depend so much on fortresses as on the efforts that can be made by a contented, brave, and patriotic people. If it is known by those who would invade us that we have not only brave hearts, skilled hands, and powerful guns, but a system of applying our resources that is capable of making any coast position formidable to war ships, that knowledge will have its effect. In war time a good general disposes of his forces in that manner which will be most embarrassing and most formidable to the enemy. In time of peace we might arrange and prepare our coast defences on similar principles.

The improved artillery applied in earthworks made thoroughly efficient on the new system, together with the facilities which the existing network of railways slightly extended would supply, should be made to go some way in meeting the corresponding advantages that have been conferred

on the power of attack by steam navies and iron-clad war ships. If my labours have in any degree the effect of diverting the great resources of this country from a more expensive to a cheaper and more efficient system of coast defence both in the colonies and at home, and if thereby the security from outrage and disaster is increased, the consciousness of having helped to do so will itself be to me a reward for the delays, anxieties, and trouble that it has cost me to bring this matter forward.

WHITWORTH METAL.

It is well known to mechanicians that Mr. Whitworth has been long engaged in testing a new process of making and casting iron or steel, which he has invented with the view of getting rid of all those accidents which arise from the air-bubbles found more or less in all iron castings, and not removable by any amount of hammering. Mr. Whitworth has now perfected a mode of casting metal which renders it so homogeneous that it resists any given forces which can be brought to bear upon it. The following notice, which recently appeared in the "Times," gives an interesting account of the application of the Whitworth metal to ordnance. The notice is written by an officer of the Royal Artillery, thoroughly acquainted with the subject:—

Mr. Whitworth has long been known as a mechanician of the highest order. To him is due the accuracy with which machinery may now be made to turn out work almost perfect in its beauty and precision of dimensions. When once the transference of circular into direct or eccentric motion and the converse was achieved, it was easy to devise a thousand means of carrying the discovery into practice, and, theoretically, of producing any, even the most delicate forms. But the main difficulty had still to be surmounted. The machines themselves were imperfect in dimensions. There was no such thing as an exact plane in existence, much less an exact sphere, or cylinder, or cone. Every part of every machine was really rough and uneven in surface, however precise it might appear to the naked eye, and it is clear that wheels of imperfect roundness, turned by equally imperfect shafts, working in imperfect beds, could never turn out perfect productions. The defects continued to reproduce themselves, for the parts of new machines were made by the old ones A beginning had to be made somewhere. Mr. Whitworth set to work to make plane surfaces of mathematical accuracy. First manufacturing three flat pieces of hard metal as exact as was possible by the ordinary means, he then rubbed two of their surfaces together till there remained no perceptible friction. He then took the third and worked it on to the two others, continuing the process till the three were so equal that, if any two of them were laid one upon the other, they touched nowhere, the upper one floating on an extremely thin film of air between them, without friction. If the edge of the upper one was pressed on the lower surface and pushed along it, followed by the body itself, there was no air between, and the two adhered together, held fast by the pressure of the atmosphere above and below. Here was the germ from which sprang exact spheres, cylinders, and wheels, the parts of machines which could be relied upon. Henceforward there was no limit to the preciseness of the productions, except the wearing of tools or of the machinery itself. But a finer test of the work was required than any then in existence, so Mr. Whitworth designed a measuring instrument, capable of marking faults for correction even if they did not exceed the millionth of an inch. So the work produced and the parts of the machines could be rigorously tried, and many a new flight could be taken in the region of mechanics.

When the demand came for small arms and cannon of longer range and closer shooting, Mr. Whitworth carried out a series of experiments for the Government, laid down what he considered to be the laws governing the rifling of barrels and the shape of projectiles, and produced a rifle which attained results hitherto unknown. He proceeded to apply the same principles to artillery, and competed with Armstrong for the position of first artillerist in the world. But his rival had already not only designed but built a large number of guns fulfilling in their construction the demands of practcal soldiers, as well as those of scientific artilleirists. The ground was already occupied, and whe n it was found that neither inventor could claim any very decided superiority over his antagonist, the strong practical objection to complication of guns and ammunition, by the adoption of two complete systems side by side, was, very properly, allowed to weigh against Mr. Whitworth. If the public service be the first consideration, many an ingenious invent,or may find that there is no room for his works though he may well deserve a handsome acknowledgment in one shape or another.

Since the days of the Armstrong and Whitworth Committee, Mr. Whitworth has never dropped the subject of artillery. It was not enough for him to beacknowledged as the first machinist in England, he must also be accepted as in the front rank of artillerists—a desire which he shares in common with many others. Such an end is only to be attained by the manufacture of reliable heavy rifled guns, such as 300, 400, and 500 pounders, or pieces of even higher calibre, and Mr. Whitworth was long unsuccessful in producing anything higher than a 7-inch gun. His system of gunnery is acknowledged by himself to be very severe upon the piece from which his long projectiles are fired, and we have more than once heard from his own lips that he sought in vain for a material which could be relied upon, and produced in sufficient quantities. He adopted a mild steel as the metal theoretically most adapted to withstand both strain and wear, but he found, as all makers of steel guns have found, that the greatest care was unavailing to produce trustworthy steel tubes in large quantities and of large sizes. Many a fair-seeming piece of a gun would stand steady strains perfectly, but crack when the sudden shock of fired gunpowder occurred within it. So much material could not be wasted without increasing the cost of that which was sound, nor could guns be produced rapidly or in large quantities. The English Government would hardly accept 9-inch guns costing £3,200 each, except for purposes of experiment, when pieces of equal calibre could be bought from Armstrong for considerably less than half the price, or manufactured in the Royal Arsenal, on Fraser's still cheaper system, for little over a fourth. Two such guns were purchased before the late Conservative Government came into office, and their shooting was, what Whitworth shooting has always been, extremely good. The experiments with them seem to hang fire, chiefly, we believe, on account of some lack of harmony between Mr. Whitworth's idea of fair experiments and those of the Ordnance Department in the War Office.

The subject would have been of little importance, but for a most interesting and valuable attempt of Mr. Whitworth to solve the one great problem of artillerists, by producing guns at once strong, cheap, and capable of being manufactured in large quantities. In spite of all researches, the reasons for the peculiar qualities of steel are still doubtful, but the most important and undesirable quality, that which breaks the hearts of gunners, is the uncertainty of the metal. Of two tubes manufactured at the same place, about the same time, by the same workmen, one may stand 1,000 rounds, and the other burst destructively at the first or fiftieth round, sometimes without the slightest warning. One reason given is, that bubbles of gas formed in the molten steel before it is set are retained by the thickening fluid, and perpetuated as flaws in the ingot, no matter how severe a hammering it may have had. Mr. Whitworth claims to have succeeded in getting rid of these gas or air bubbles entirely by the application of immense pressure to the mass of molten metal while cooling. He has four qualities of this steel, or "Whitworth Metal" as he calls it. They are known as yellow (having most carbon), blue, brown, and red, the red being the most ductile. He has tried many experiments on a small scale, and considers himself to be justified in declaring that he will now be able to make heavy guns perfectly trustworthy at a price of about £120 a ton, or one-fifth higher than Sir W. Armstrong's present prices, and rather more than half his own old ones. A 9-inch gun would cost £1,800, but then its projectiles would be heavier, and its power greater than its rival of the service pattern. Mr. Whitworth is pre-eminently an advocate of small bores in guns as well as rifles, being ready of sacrifice many practical advantages for good shooting. He now asserts that he throws to the winds all fear of his guns bursting. Instead of seeking for powder of less severity, his only wish is to find means of igniting it more rapidly, and he is making preparations for the construction of 27-ton guns, or even pieces weighing over 43 tons.

It may be that Mr. Whitworth has achieved a task which would certainly lead to the adoption of his metal for the inner tubes, at least, of all guns, whatever might be their system of shooting; but the experience of all practical artillerists denies them permission to accept experiments on a small scale, as applicable to heavy guns, in which the force of the explosion is vastly multiplied, possibly even altered in its mode of action. The Government possesses two heavy Whitworth guns, but they are not made of the new metal, except in very small proportion applied to the exterior of the piece. They may be very useful to test ammunition, system of rifling, and so on, but their lasting qualities will prove nothing as to the strength of the new metal for guns, because they are made of the old metal. We understand that the superintendent of the gun factories applied to Mr. Whitworth for inner barrels, but was answered that the whole system or nothing must be taken. This seems a little obstructive; but here is a man of reputation asserting that he has the power of producing metal of extraordinary strength, and that he has actually commenced to make two 11-inch guns calculated to fire shells of 960 lbs. If he will not allow his material to be tried as part of the Government ordnance, we cannot but think that it would be worth while to order one gun from him, embodying his newest ideas, and test it in every way without competition, for it seems that in this way alone can the authorities arrive at truth regarding the strength of the Whitworth metal as applied to heavy guns. It should be distinctly understood that Mr. Whitworth's system of charges and projectiles is acknowledged by him to be extremely dangerous to the endurance of the pieces of ordnance themselves, and must be rejected unless he can find material to bear the severe strain put upon it. If the new metal fails, his case falls to the ground; but it is surely worth a trial.

There is, however, another experiment possible to be carried out with the two costly guns now in the hands of the authorities. Mr. Whitworth insists that flat-headed shot or shells, very long, and therefore containing a large bursting charge, are the proper projectiles to fire at iron plates, especially when the target stands obliquely to the line of fire. We have inspected certain plates containing holes pierced or punched by flat-headed projectiles fired from the Whitworth 1¾-inch gun of 7 cwt. A plate of equal thickness with the shell was completely pierced at an angle of 45 degrees, and with a charge of 10oz. At an angle of 65 degrees the shell did not pass through, but made a ragged hole. At right angles it passed easily through a 2¼-inch plate. A service gun of equal weight would have a calibre of three inches, and be capable of piercing at least the 2¼-inch plate directly, probably a 3-inch plate. But it is not with these tiny pieces of ordnance that artillerists' attention is now chiefly occupied, at least out of England. The great point is to make guns and projectiles that will pierce iron-clad ships at all sorts of angles. The rough-and-ready rule with our service guns is, that a shot or shell will pass through an iron plate somewhat thicker than its own diameters; 9-inch projectile through more than a 9-inch plate, &c. But Mr. Whitworth contracts the diameters of his projectiles for the same weight both of gun and ammunition. He makes his shells long and narrow, so the rough rule has no application to them. We should very much like to see what target would be pierced by the Whitworth guns with Whitworth flat-fronted projectiles, and at what angle. The experiment is surely worth the small sum of money it would cost. It is of no use to point to experiments made with 2-inch guns. All working artillerists have been disappointed, over and over again, at the difficulty of getting big guns to do as well, in proportion to their bulk, as small ones. But there are the big guns, why not try the long, flat-fronted projectiles? When the question comes before Parliament it is sure to be made as foggy as possible. Let us try for once to state it clearly.

Whitworth's system of artillery consists essentially in small-bore guns with long projectiles. The twist of the rifling must be rapid, because otherwise the long projectiles would turn over. All this involves a great strain upon the interior of the gun. Until now he has not succeeded in making heavy guns to stand this strain, except in small numbers, at a prohibitory price. He now asserts that he has found the material he has so long sought; but there is, as yet, no heavy gun in existence made of this material. We say, let him make one, and let it be tried. Then, there is that other question of his shells, which has nothing to do with the gun question, and may be settled by firing some projectiles out of the costly pieces now in possession of the Government. If the shells succeed, it will be interesting to know whether Mr. Whitworth can really make guns at a reasonable price capable of firing them. Then will come the last question, perhaps more difficult still to answer, where can such guns be placed without involving such a complication of ammunition and stores as would be detrimental to the public service? We hold that Mr. Whitworth has made out a case for experiment.

EXPANSION OF MINERAL OILS.

M. DEVILLE recently presented a paper to the Academy of Sciences at Paris on the physical character of mineral oils, in which he mentions the increase in bulk occasioned by an elevation of temperature as a prominent cause of danger by fire where petroleum may be stored. The "Tidioute (Pa.) Journal," in relation to this statement, says:—From long experience, oil dealers in this country have come to be well aware of the fact of such expansions, although without, in most cases, any idea of its amount. This is odd enough, too, when we consider the constant use made of olemeters, "measures of the density of oil." For this reason, the following remarks may not be inappropriate: "The scale of Baume's hydrometer, olemeter, or densitometer, a wholly arbitrary one, represents for each degree within the usual limits of crude American petroleum, as nearly as may be, four and a half thousandths of the density of water at 60deg. Fah. As every increase of temperature of 10deg. Fah. equals a decrease in density of 1deg. B., the expansion of oil may be taken, without sensible error, to be .00045 of its bulk for each degree of Fahrenheit's thermometer. Allowance for expan-

sion is always made in shipping oil, except in the old-fashioned wooden tank cars, where the oil is permitted to force its way through the hatches, roofs, and sides of the tanks. In shipping in barrels it is customary to leave about one gallon 'outage,' as in 50deg. (which may be considered the extreme variation in temperature likely to occur while the oil is in transit) 44 gallons would become 45. It would be safer and more economical to allow yet greater room, were it not for the advantage, in that case, apt to be taken of the shipper by the consignee. The allowance for expansion in Empire Line iron cars is very large, consisting of a cylindrical dome, about 40in. in diameter, and 30in. high—the capacity of which is about 4 per cent. of the whole car; 50deg. of temperature representing an expansion of but 2½ per cent. it is evident that these Empire iron cars are as safe and economical as they are convenient. The writer has no knowledge of the empty space left in the five-gallon cans so largely used for exported refined, but 5in. square by 1in. high would be sufficient. The increase in bulk, in the summer, of oil stored in iron tankage in winter is of considerable importance in these times of high prices. A twelve thousand barrel tank is 60ft. in diameter and 24ft. high, and holds in each inch of its height 1762·56 gallons. The mean temperature of oil here in Tidioute is, in winter, about 20deg. and in summer 70deg. both very nearly. The range being thus 50deg. the volume of oil to each inch, at 20deg. Fah., is increased 39.66 gallons; but as the tank has also grown larger, this amount is not shown by measure. Iron expands .000006964 for each degree, or for 50deg. about three and a half ten thousandths; so that the circumference of the tank is increased .7917 of an inch—the diameter by .252 of an inch; and the capacity for each inch height by .62 of a gallon. Therefore the apparent gain is only 39.04 gallons for each inch of the tank at 20deg. It is to be noted, however, that no allowance is here made for the fact that the temperature of the tank is always higher or lower than that of the oil; that the yearly mean is greater than 50deg. Fah., and that nothing was said of the increased height of the tank. All of course for the reason of their insignificance, and because the expansion of the iron was taken as not interfering with the figures of the tank."

SEPARATING ANIMAL FROM VEGETABLE FIBRE.

IN mixed fabrics or fabrics composed partly of animal and partly of vegetable fibres, the separation of animal fibres, such as, for example, wool, hair, or silk, from the vegetable fibres, such as cotton, flax, or jute, is a process necessary for certain purposes. The plan hitherto adopted for the purpose of separating these fibres has been to treat the material to be operated upon with acids. This is, however, objectionable, as the animal fibre is by their action rotted, and thereby loses its milling and felting properties. In a recent patent, Mr. James Stuart, of 40, Ropemakers' Fields, Limehouse, dispenses with these acids, and substitutes neutral substances. In this way, rags, carpet cuttings, old carpet, and other waste material of mixed fibres may be utilised to a greater extent than has hitherto been found practicable, and, as the separated animal fibre retains in most cases its colour, it can oftentimes be worked up again into articles for use without the necessity of its being re-dyed.

His invention consists in subjecting rags, carpet cuttings, old carpet, or other material of animal and vegetable fibre intermixed to the action of chlorides of the metals or sulphates of the oxides of the metals, preferring, however, to use as the active agent the chloride of aluminium. In thus treating the material, certain chemical reactions take place whereby the vegetable fibre is decomposed and the animal fibre is recovered uninjured either in substance or in colour. It is then in a fit state to be re-manufactured without re-carding, spinning, dyeing, or other operations that have hitherto been necessitated.

In practice, Mr. Stuart first makes a solution of ingredients in the following proportions:—In 100 gallons of hot water dissolve 100lb. of the sulphate of alumina of commerce; then add 50lb. of chloride of sodium; when this last-named ingredient is added, a reaction takes place; sulphate of soda is formed, and also chloride of aluminium. With the solution thus made the material to be treated is saturated. It is then drained so as to allow the excess of the solution to pass therefrom; or the material may be slightly wrung or pressed for the same purpose. The material is next dried and afterwards exposed to a steady temperature of 200deg. Fah. During the time of this exposure, the chloride of aluminium decomposes, and the resulting volatile products, as they pass off, act upon the vegetable fibre, rotting them, but leaving the animal fibre uninjured. The material treated is then scribbled, and the vegetable matter separates in the form of dust. This treatment refers more particularly to rags of light mixed fabrics.

When treating heavier or denser material, such as carpet cuttings or old carpet, the solution of chloride of aluminium is of greater strength. In 100 gallons of water dissolve 150lb. in weight of sulphate of alumina and 75lb. of chloride of sodium, and then proceed in the manner before described.

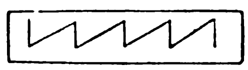
In some cases, it is found more convenient to treat the material by boiling than by heating in drying rooms. Mr. Stuart then proceeds in the following manner:—He makes a solution of sulphate of alumina by dissolving 100lb. of that substance in 100 gallons of water, and with this solution, he saturates the material. It is then drained, and afterwards placed in a boiling saturated solution of common salt. In this solution, the material is kept boiling until the vegetable fibre is decomposed or rotted; the material is then well washed and dried, and scribbled or carded.

Correspondence.

RIFLED *v.* SMOOTH-BORE GUNS.

TO THE EDITOR OF THE "MECHANICS' MAGAZINE."

SIR,—Permit me to place before the public, through the medium of the MECHANICS' MAGAZINE, a few thoughts on guns, rifling, and projectiles. I have discovered that a smooth-bore gun, with a suitable projectile, will shoot as accurately as a rifled gun; and that all that is required to answer this end is to flute spirally a cylindrical shot with a number of shallow grooves inclined to its axis at an angle of 45deg. The projectiles I have used have been flat at both ends. Suppose an 8in. shot, 2½ diameters in length, to be fluted with ninety-six grooves of this form—



each groove ⅛in. deep and ¼in. broad, the perpendicular side of the groove being the driving side; then, in this shot, we have 96 ⅛in. = 12in., the depth of all the grooves, and 20in., the length of the shot, giving a space of 20in. by 12in., or an area of 240 square inches, which is presented at right angles to the action of the inflamed gases. Thus, with an average windage of 1-16in., we have an area presented for rotation equal to five times the area presented by the shot for projection. The length of the shot may vary from half to three times its diameter. I have used a plano-concave wad made of tallow, with as slight a covering as possible to prevent choking the grooves; and I find that little more than the wad needs to escape in order to produce the rotation required. The cost of grooving would be small. Projectiles to be fired from the shoulder may be made in the way of lead pipe, or be pressed into form at once. Heavy shot will required coating with some soft metal in which the grooves may be cut in a few minutes.

It has been objected that the rotation of such a shot would be impeded during its flight by the action of the atmosphere on the inclined planes. I grant this; but I consider the effect to be so small that it may safely be passed unnoticed. However, the objection embodies a great idea. It is this—if the resistance of the atmosphere to the flight of a projectile will retard its rotation when acting on a number of planes inclined in one direction, then it is clear that if these planes be inclined in the other direction, the resistance of the atmosphere will accelerate its rotation. The whole of the resistance of the atmosphere to the flight of a projectile may be converted into a power which will increase its rotation in the ratio in which its projectile motion diminishes. Thus a shot may be sent five miles and possess the same quantity of motion with which it leaves the muzzle of the gun. Suppose a shot, the end of which presents to the atmosphere four inclined planes, inclination 45deg., to bury its jagged front in an iron plate at a distance of three miles, and there spend its projectile force, what would be the effect of the force accumulated during its flight from the resistance of the atmosphere? that is, what would be the effect of the rotation of the shot? I leave this to be answered by experiment.

If we are to have rifled guns and not plain bores, by no means let the rotation be produced by one piece of metal grating against another when it can be done without. In the small bore, the direct action of the gases upon the projectile will produce rotation by means of an escapement; in a rifled bore, the direct action of the gases upon the projectile will produce rotation without an escapement. Suppose a gun to be rifled parallel with its axis with one groove ½in. broad and ½in. deep. On the projectile is a rib projecting ½in. and ¼in. thick. This rib is inclined to the axis of the shot, so that, at one end of the shot, it touches one side of the groove, and the other end the other side, leaving a space of ¼in. on opposite sides at opposite ends. The rib thus lying across the groove fills it so as to prevent any escapement, though itself only ¼in. thick. If such a projectile be fired from such a gun, the rear end of the rib will be forced against that side of the groove that it touches, by the force of the gases, along the whole of its passage through the bore, the gases acting on one side of the rib, but not on the other.

Now, suppose the rifling of the gun to be spiral, and the pitch of the rib on the shot to be so much slower than that of the rifling that its opposite ends touch the opposite sides of the groove; then, in this case, as the side of the groove against which the rib is forced recedes all the way along to the muzzle, it is followed by the rib, which is forced against it by the gases, and thus rotation is produced. In this way a very quick pitch o rifling may be used without depending at all on the shot coming in contact with the rifling in order to produce rotation. The ribs may be varied as to form and number to suit anyone's fancy. I think, if our artillerists will take these few hints into their study, we shall soon see some different practice from that we are accustomed to.—I am, Sir, yours, &c., EDWARD HOYLE.

Crossbank, Meadow Bottom, Todmorden, October 18.

SUN SPOTS.

SIR,—In the diversity of opinion entertained by scientific men upon the nature of the spots that appear periodically upon the surface of the sun, there does not appear one that offers a satisfactory explanation. It is in the solar investigations, although we behold the flame and feel the heat, science remains unsatisfied. The absence of a superior mechanical invention retards the progress of philosophical ideas. But it appears to me that the elucidation of these phenomena does not altogether depend upon mere mechanical ingenuity. There is a higher philosophy. In the earth, we behold the features of a convulsive energy that has long ceased to exist. The spasmodic efforts which history records appear but the expiring efforts of that igneous or active state of which the central body of our system is the representative. In the great cavities now filled with the waters of the earth, we may trace the most intense action at the period of transition. The oceans, seas, &c., that fill those cavities are evidences of the convulsion. The more elevated parts, or those the least exposed to violent action, must (as in the sun) have become periodically exposed from the more united action of the surrounding bodies. It is these portions of the body of the sun that we behold. The attempts to explain these phenomena by clouds and caverns are unworthy the magnitude of the subject. The only way it can be philosophically explained is by observing the position of the various bodies which compose our system at the time of their occurrence.—I am, Sir, yours, &c., H. SALOWAY.

13, Standard-street, Dover-road, October 20.

PLAITING MACHINE.

SIR,—Can any of your readers inform me where I can purchase a plaiting machine for hemp and fibrous materials for engine packing? By so doing, they will oblige, Sir, yours, &c.,

J. E. REEVE.

Wolverhampton, October 16.

THE office of "Master of the Mint" is vacant. "Punch" says there can be but one opinion as to who should have the appointment—Mr. Lowe. He will then be able to do what he pleases with the sovereign, and having both the Exchequer and the Mint under his control, his happiness will be complete, unmixed with alloy!

TO CORRESPONDENTS.

The Mechanics' Magazine is sent post-free to subscribers of £1 1s. 8d. yearly, or 10s. 10d. half-yearly payable in advance.

All literary communications should be addressed to the Editor of the Mechanics' Magazine. Letters relating to the advertising and publishing departments should be addressed to the publisher, Mr. R. Smiles, Mechanics' Magazine Office, 166, Fleet-street, London.

To insure insertion in the following number, advertisements should reach the office not later than 5 o'clock on Thursday evening.

We must absolutely decline attending to any communications unaccompanied by the name and address of the writer, not necessarily for insertion, but as a proof of good faith. Ed. M. M.

Advertisements are inserted in the Mechanics' Magazine, at the rate of 6d. per line, or 5d. per line for 13 insertions, or 4d. per line for 26 insertions. Each line consists of about 10 words. Woodcuts are charged at the same rate as type. Special arrangements made for large advertisements.

Naval, Military, and Gunnery Items.

The death is announced of M. Borel, chief engineer of the works on the Isthmus of Suez Canal. The deceased was in his 48th year.

The fetes to be given at the inauguration of the Suez Canal will commence on the evening of November 16 at Ismaliar, and terminate on November 19 at Suez.

Several old guns converted into 64-pounders at the Royal Gun Factory Department, Woolwich, have just been put through the usual proof at that proof-butt and stood the test satisfactorily.

The ceremony of handing over into the custody of the Duke of Argyll the old colours of the 91st Highlanders, lately replaced by a new set, took place at Inverary Castle this day week.

The "Levant Herald" says that the question of opening the Dardanelles and the Bosphorus for navigation at night by merchant vessels has been solved, by the Porte having consented to allow in future out-ward bound vessels to pass through both, Straits at night.

The fishing smack "Jeune Desiree," of St. Malo picked up a dead porpoise, weighing 600lb. a few days ago. On opening it 23 cuttle fish were found in its stomach. It measured 8ft. in length, and, judging by the teeth, was of a great age. Some of the cuttle fish had got into the windpipe and choked it.

The "Monarch" will be undocked at Portsmouth on the 2d proximo. In addition to the alterations and repairs being carried out with her steam and other machinery, the area of the fore part of her balance rudder is being reduced, and the hull of the ship below the water line is being re-coated with Dr. Sims' anti-fouling composition.

This day week at Shoeburyness the 9-inch rifled wrought iron howitzer fired seven more rounds with 4lb., 6lb., and 8lb. charges, and light projectiles of 200lb. the full charge being 9lb. with 250lb projectiles. The practice has been temporarily stopped on account of the leakage of the gland of the hydraulic buffer, through its not having been properly packed.

It is understood that the Ocean Tea-Ship race has been won by the "Sir Lancelot," Captain Robinson, which left Foo Chow Foo on the 18th of July, and arrived in the East India Docks on Thursday morning week after a passage of eighty-nine days, said to be the shortest on record. The "Sir Lancelot" is a Clyde clipper. She was first in the tea race in 1867, and lost it last year only by a few hours.

We understand that the French Government is about to establish a great central school in Paris for the instruction of youths intended for the navy and mercantile marine. The education will not only include navigation and all connected with it, but the pupils will also receive a thorough commercial education, so as to render them fit for employment in any part of the world.

The "Sultan" is making very good progress, a large force of men being employed on her. Large numbers of heavy armour-plates have been affixed to her port side, and others continue to arrive from the contractors. Workmen are engaged in preparing the starboard side of the vessel for the reception of armour-plates. It is expected that this formidable ship will be ready for floating out of dock about next May.

In a return just issued the total amount received for pilotage of vessels in the port of London in 1868 is stated as follows:—British vessels, not towed by steam, £4,573 13s. 6d.; towed by steam £37,051 15s. 7d. For foreign vessels, not towed by steam, £16,117 9s. 4d.; towed by steam, £18,086 10s. 1d. For outward pilotage, British vessels, not towed by steam, £1,805 15s. 2d.; towed by steam, £24,217 19s. 4d. For foreign vessels, not towed by steam, £8,475 10s. 10d.; towed by steam, £9,714 15s.

The new wrought-iron pier, constructed opposite the Royal Gun Factory Department, Royal Arsenal, is nearly completed. The pier is supported upon iron columns and has a plain and neat appearance; it has a tramway running the whole length, about 350ft., and has three lines of rails upon it. The pier is intended for heavy stores to be conveyed over it from the shipping to the wharf, the depth of water being sufficient for vessels to be brought longside to disch rge.

Miscellanea.

The death is announced of the sculptor Pierre Hebert, author of the well-known group of the "Child and the Tortoise."

Professor Becas has now finished his statue of Schiller, which is to be erected in Berlin, and will shortly place it at the disposal of the commission.

Mr. Thomas Ball, an American sculptor in Florence, has just completed, for private commission, a statue of Eve, which will be for some days on view at his studio.

The number of visitors to the Patent Office Museum, South Kensington, for the week ending October 16, was 4,375. Total number since the opening of the Museum, free daily (May 12, 1858), 1,667,032.

It is at last definitely arranged that the new bridge at Blackfriars and the Holborn Valley Viaduct are to be opened on Saturday, November 6. Her Majesty will be present, and the proceedings will be marked by stately ceremonial.

The City Gas Company have notified that, in accordance with the City of London Gas Act, 1868, the price of ordinary gas supplied by the company from and after January 1 next will be reduced to 3s. 9d. per 1,000 cubic feet, and that the illuminating power will be raised to 16 candles.

The powder works belonging to Messrs. Dixon and Co., situated about four miles from Lake Windermere, was the scene on Tuesday morning of a devastating explosion. The press and charge houses were utterly demolished and six mills completely wrecked. Unfortunately, there were three men at work at the time and they were blown to atoms.

The University of the South, the condition of which at the close of the civil war in the United States elicited so much sympathy from the English bishops and the Universities of Oxford and Cambridge, has conferred its honorary degree of D.C.L. on the Rev. F. W. Tremlett, vicar of St. Peter's, Belsize-park, honorary secretary of the fund raised in this country on behalf of the University.

The Middlesborough Association of Managers' Foremen, and Draughtsmen connected with all branches of the iron trade, is now fairly in existence, and at its first meeting on the 16th inst., 26 members were enrolled. Mr. John M. Oubridge, late of London, has been elected first chairman of the infant society, which has the whole of the Cleveland district for its field of action, and is therefore likely to be largely supported.

The number of births and deaths registered in the parish of Clifton (Bristol) for the quarter ending September last was as follows:—Births: boys, 84; girls, 82; total, 166. Deaths: males, 42; females, 56; total, 98. Of the deaths registered, 11 were aged 80 years and upwards—viz., one 96, 92, 91, 90, 88, 87, 85, 84, and 83 respectively, two 80 each—and seven 70 years and under 80. The return also includes the deaths of 19 children under one year old.

Consequent upon the repeated complaints of the inhabitants of the south of the metropolis respecting the quantity and quality of the water supply, and which have found expression in memorials to the Board of Trade, the companies are increasing the number of their filtering beds at Battersea, and a new store and subsidence reservoir is being constructed to contain a depth of 14ft. of water (25,000,000 gallons).

The number of visitors to the South Kensington Museum during the week ending October 16, 1869, was—on Monday, Tuesday, and Saturday (free), from 10 a.m. to 10 p.m., 14,029; Meyrick and other galleries, 1,867; on Wednesday, Thursday, and Friday (admission 6d.), from 10 a.m. till 5 p.m., 2,015; Meyrick and other galleries, 135; total, 18,046. Average of corresponding week in former years, 12,149. Total from opening of Museum, 8,886,448.

The awards to the successful exhibitors at the Netherlands Exhibition were on Monday distributed by Prince Alexander in the name of the King. The ministers of State and the representatives of the various countries took part in the ceremony, and a report was read by Baron Mackay, the president of the central jury, as to the result of the exhibition. A large company assembled at the banquet given in the evening, illuminations and a display of fireworks bringing the exhibition to a close.

A congress of wine growers is to take place at Beaune, France, on November 8, 9, and 10. The following questions will be discussed:—1. On the means of interesting the labourer, by association or otherwise, in the success of the culture. 2. On the system of *metayage*, or a division of the crop between the landlord and the tenant, applied to vineyards. 3. The necessity of a school for instruction in the cultivation of the vine. 4. The intervention of the authorities in fixing the date of the vintage, &c. 5. On the use of machinery to meet the insufficiency of labour, as well as ploughing, vine props, &c.

At the meeting of the Royal Horticultural Society on Tuesday, in consequence of the inclement weather, fewer plants were exhibited than usual, though the orchids were magnificent, especially Vanda Cærulea, from the gardens of Lord Londesborough. Mr. James Bateman, F.R.S., presided, and called the attention of the meeting to a specimen of the Avocado pear as it is called (Persea gratissima), a fruit never before produced in Europe, and never plentiful even in the tropics; an exceedingly wholesome fruit, and larger even than any of the monster pears exhibited in Covent Garden. Mr. Charles Morgan was elected a fellow.

With reference to the application of sewage manure to farming purposes at Aldershott Camp, some of the members of the local board of health, who are practical farmers, while they do not impugn the accuracy of the statements published with regard to the crops realised, assert that the system nevertheless fails to remove the nuisance which before existed, and that the sewage water after filtration, although clear in appearance, gives out a most offensive odour, which prevents the beneficial occupation of any property adjoining the camp farm. The local board has been threatened with an action for conveying the sewage of the town of Aldershott into the Blackwater River, and, so far from concluding the experiments to be a solution of the problem of sewage utilisation, the board has resolved to memorialise the Home Secretary before carrying out any general plan of drainage.

The Serpentine is at last to be levelled to a uniform depth of 5½ft., and an attempt will be made to purify it from the filth which for several years past has been a source not only of disgust but of danger to those who have been in the habit of bathing there. It may not, perhaps, be generally known that previously to the Metropolitan Main Drainage scheme, certain sewers emptied their contents into the Serpentine, and, as there is no outlet, these deposits, with the rotten weeds accumulating, often produced in the summer months an effluvium which was at times almost insufferable. At the close of last session, after some opposition, a vote of £13,000 odd was passed for "reducing the depth, purifying, and otherwise improving the Serpentine," and the work will be forthwith proceeded with. As has been stated, it is intended to level it to a uniform depth of 5ft. 6in. and cover the bottom with a layer of concrete. The works, it is anticipated, will be completed by the ensuing spring.

On August 21, at eight minutes past three in the afternoon, a very alarming shock of earthquake was felt in and around Schemacha in the Caucasus, which destroyed not only the greater part of the houses in the town, but also those of the village of Sundi, at the distance of 18 versts. The approach of the catastrophe was announced by many precursory indications, such as the water in the fountains turning muddy and the prevalence of an odour like that of garlic in the air. Immediately before the shock, a noise like subterranean thunder was heard, and, at the same moment, dense columns of dust appeared moving from east to west. The magnet lost its attractive power.

An insect, pronounced by local naturalists to be a locust, has just been captured in Waterford. It flew into the open window of one of the houses on the quay on Sunday last, and was caught by the servant. The animal is about 2¼in. long, and of a greyish colour, with long narrow wings that meet near the tail, and are "humped" at the shoulder. At first sight, the animal appears like a huge dragon fly. There has been a large arrival of foreign grain vessels in Waterford during the past fortnight, and it was in a house opposite to where several of these vessels were moored that the locust took refuge on Sunday. No doubt, it was by means of one of those ships the creature was imported.

A correspondent of the "Times," writing from Transylvania, thus describes the happy town of Szék:—"Where no one is in absolute want, and

all are more or less on the same level, the greatest incitement to crime is gone; and so it is in this Transylvanian Arcadia. Except now and then a row on a Sunday evening, there is but little for justice and police to do, and even these rows can only be of rare occurrence when, in a population of 5,000 souls, only half a dozen are known as drunkards. Theft is unheard of; not a house has a lock; agricultural implements are kept in the fields; household property in the open courtyards, where not even watch dogs are kept. There is, indeed, a prison remaining, but it has been used for years as a lumber room."

On July 30, a flight of locusts, two and a half miles long by one and a half broad, going from west to east, passed over Rewarree Tehseel in the Goorgaon district. They deposited some eggs which were destroyed by the ploughing up of the land, and but slight damage was done to the crops. On August 2, the same or a smaller flight appeared in the same locality, moving in the same direction; it did no damage. On August 3, a flight extending six miles by two and a half, but moving from east to west, was observed in Tehseel Goorgaon, and on the following day a smaller flight moving south was seen in the same locality. In Tehseel Loodianah, on August 8, a very large flight appeared, but were not suffered to settle on the crops, shouting and tom-tomming having driven them away, though not before they had injured a number of trees.

Patents for Inventions.

ABRIDGED SPECIFICATIONS OF PATENTS.

The Abridged Specifications of Patents given below are classified, according to the subject to which the respective inventions refer, in the following table. By the system of classification adopted, the numerical and chronological order of the specifications is preserved and combined with all the advantages of a division into classes. It should be understood that these abridgments are prepared exclusively for this Magazine from official copies supplied by the Government, and are, therefore, the property of the Proprietors of this Magazine. Other papers are hereby warned not to produce them without an acknowledgment:—

Boilers and Furnaces—909, 945, 954, 959, 960

Buildings and Building Materials—893, 901, 916, 928, 967, 975

Chemistry and Photography—939, 942, 969

Cultivation of the Soil, including agricultural implements and machines—912, 927, 964, 968

Electrical Apparatus—917, 919

Fibrous Fabrics, including machinery for treating fibre pulp, paper, &c.—918, 926, 953, 955, 963, 980

Food and Beverages, including the apparatus for preparing food for men and animals—920, 924, 978

Furniture and Apparel, including household utensils time-keepers, jewellery, musical instruments, &c.—923, 930, 932, 936, 944, 946, 948, 957, 966, 979

General Machinery—902, 913, 915, 933, 970, 971

Lighting, Heating, and Ventilating—956

Metals, including apparatus for their manufacture—905, 908, 942

Miscellaneous—903, 904, 906, 911, 914, 925, 937, 940, 943, 961, 972, 973

Roads and Vehicles, including railway plant and carriages, saddlery, and harness, &c.—922, 931, 9414 9 950, 951, 952, 958, 962, 974, 976

Ships and Boats, including their fittings—934

Steam Engines—965, 977

Warfare—910, 929, 938

895 J. Nevill, Abergavenny. *Securing window sashes* Dated March 24, 1869.

This consists in fitting a strip of wood or metal in front of the cords or lines by which the sashes are suspended. The strip is connected at its upper part by a link to the main frame, and is free to be moved inwards into the box in order that a pin or stud in it may be released from a hole in the upper sash and removed from bearing on the lower sash. This invention also consists in the employment of a clip or support by which the weights are held or supported when the sashes are closed. The clip or support is connected to the back of the strip of wood or metal before mentioned, and removes the strain of the weights from the cords.—Patent completed.

901 J. Woodhead, Bradford. *Flooring cramps.* Dated March 24, 1869.

This cramp consists of a screw spindle supported so as to be capable of sliding endwise, but without turning, in two bearings of a suitably formed frame of metal or other material, and betwixt these bearings is a bevel wheel, the boss of which is screwed to fit the spindle.—Patent abandoned.

902 W. J. Cunningham, New Oxford-street, and A. M'Carthy, Broad-street, Middlesex. *Motive power.* Dated March 24, 1869.

In a suitable frame are placed two cylinders containing springs, the cylinders being free to revolve partially on their axes, or the cylinders and their axes may revolve together when required. To any convenient part of the periphery of each of the cylinders is fixed a chain or its equivalent, the other ends of which are attached to levers having their fulcrums on suitable hollow bosses fixed to the frame and surrounding the shaft carrying the driving bog wheel. This wheel is supplied at suitable points near its periphery with pins or projections against which the levers press when operated upon by the springs, thus causing the bog wheel to rotate, and by means of intermediate cog gear of any desired multiplicity imparting its motion to one or more pairs of carrying wheels, by which means the machine is caused to travel, or cranks may be used with the cog wheel when required.—Patent abandoned.

903 E. Peyton, Birmingham. *Printing rollers.* Dated March 24, 1869.

A hollow cylinder made of a comparatively base metal or alloy, such as spelter brass, or other suitable metal or alloy, is combined with a surrounding surface of superior metal such as copper, or a superior quality of brass or alloy, so that the superior metal or alloy and the baser metal or alloy are united by fusion at the part where they come together.—Patent completed.

904 W. R. Lake, Southampton-buildings. *Folding paper* (A communication.) Dated March 25, 1869.

The paper to be folded is placed upon a table with its lower edge against the gauges so that the nippers, in approaching to grasp the sheet, will pass under its edge. The back board, against which the outer edge of the sheet is held, is so adjusted that the margin in the centre of the sheet through which the second fold passes shall be at right angles to the first set of rolls and in the centre of the same. The rolls which make the first fold are held horizontally in bearings secured on the frame of the machine. The first, or the roll nearest the table, is furnished with grooves, and the second roll is provided with spring bearings. Below these rolls and placed at an angle of 45deg. with them, is an inclined table formed of bars, on which the sheet is received from the first rolls. In the centre of this table the inclined rolls which produce the second fold are placed; these rolls are held in bearings secured to the cross bars of the frame.—Patent completed.

905 J. J. Bodmer, Newport, Monmouth. *Iron and steel.* Dated March 21, 1869.

In order to facilitate and regulate the cooling of the liquid iron or its alloys, or other metal or alloys, so as to expose the same to the action of the rolls just at the right time when it passes from a liquid into a more or less congealed condition. The inventor allows the same to run on plates or trays, the rims or sides of which determine the thickness of the layer. These plates or trays may be connected together and be formed into chain so as to find themselves by rotation passing over the rolls at the moment the iron is in the proper condition to be laminated or ground. When a plate reaches this position, it is made to tilt or swivel, and thereby to drop the charge on to and between the rolls.—Patent completed.

906 F. Hurd, Rochdale. *Excavating coal.* Dated March 25, 1869.

This consists in cutting horizontal, longitudinal, radial, and diagonal grooves in the coal or other mineral to be excavated by means of a series of link stocks containing the cutters, which are jointed together in such a manner that no rivets or connecting pins are required. This series of cutters passes around a pulley mounted in a radial arm and around a tooth wheel fixed to a shaft which fits in a telescope frame to increase or reduce its length. The radial arm is provided with grooves, which support the back of the cutter stocks and prevent them from being drawn out of the groove in the radial arm.—Patent completed.

907 The abstract of this specification will appear in a future number.

908 J. H. Johnson, Lincoln's Inn-fields. *Iron and steel.* (A communication.) Dated March 25, 1869.

This consists in lining the furnaces or apparatus employed in what are known as the Bessemer and Martin processes, or in analogous processes, with refractory magnesian products in lieu of using for that purpose as heretofore ordinary products, that is to say, silicate of alumina, which contains more or less of free silica.—Patent abandoned.

909 T. Champion, Northampton. *Flues and chimnies.* Dated March 25, 1869.

This consists in constructing flues with a passage for the combustion to pass off into the atmosphere, in combination with a separate and distinct passage leading from the outer air, at or near the top of the flues to the lower part thereof, terminating above the chimney bar or thereabouts.—Patent completed.

910 J. T. Greenfield, Dover. *Cleaning ordnance.* Dated March 25, 1869.

This consists of a brush made of coir (or bass) let into a drum of wood similar to that of the sponge head at present used; the bristles are set circularly around the drum, so that they have a lay or incline all in one direction horizontally. The inventor also proposes to form the hinder part of the brush head smaller in diameter than its fore part, and have the bristles longer than those in front, for the purpose of enabling the longer bristles to sweep well into the deep grooving of rifled guns.—Patent abandoned.

911 T. Baker, Duke-street, Brighton. *Fire escapes.* Dated March 25, 1869.

This consists of a strong box with a large eye painted white, which hooks upon a bracket previously fixed for the purpose only upon the top of the window. Inside this box there are four wheels working at the top. In the centre are three blocks with running wheels, and below these four strong rollers, one of which is cased with india-rubber about ¼in. thick, which form three very strong breaks.—Patent abandoned.

912 W. C. Dreyer, Gresham-street, E.C. *Tilling machine.* (A communication.) Dated March 25, 1869.

The inventor employs an axis mounted in a suitable frame or carriage, and which is caused rapidly to revolve whilst the carriage moves forward at a comparatively slow speed. On this axis a number of discs are fixed a short distance one from another and obliquely to the axis. They have upon them saw-like teeth, which are set to cut into the ground to any depth desired.—Patent abandoned.

913 J. T. Calow, Staveley. *Mining hoists.* Dated March 25, 1869.

This consists in the use of a spring or springs and a weight or weights, connected with and acting upon mechanical contrivances for gripping the slides or guides or conductors. In case of accident, these springs have a bearing or foundation on the cage or hoist while the weight or weights hang from or rest upon them, either directly or otherwise, so as to neutralise or counteract their tendency to bring the grips into action while the cage or hoist remains suspended or supported. The inventor also employs a check rope, or chain, or equivalent, to prevent accidents arising through "running," caused by overloading or by the breaking of the driving belt or from other cause.—Patent completed.

914 C. Marsden, Kingsland-road. *Water-tight flexible joint.* Dated March 25, 1869.

This consists in forming a flange on the end of a pipe (say No. 1 end), upon which flange a screw thread, rings, or other circular projections are formed. The opposite end of the pipe (say No. 2 end) is formed with a bulge or protuberance on the exterior thereof, which bulge has also a thread, rings, or circular projections on it in a similar manner to the end No. 1. The spaces between the threads or rings are fitted with yarn or other packing medium; two of the pipes are brought together, that is to say, the No. 1 end of the pipe is brought againt No. 2 end of another pipe, and the two ends are connected by being enclosed between two half rings or plates.—Patent completed.

915 W. R. Lake, Southampton-buildings. *Pressing oil tobacco, and cotton.* (A communication.) Dated March 25 1869.

The inventor connects with the bed plate, and the head plate uprights or posts. Between the latter, a follower is caused to slide to compress the material between it and the head plate. These parts are like those of a hydraulic press. Between pairs of posts the inventor places a standing frame which supports the several parts, the combined action of which operates the follower. The follower frame has grooved guides at each side of the standing frame.—Patent completed.

916 W. Meakin, Great Wood-street, Marylebone *Window sashes.* Dated March 25, 1869.

The sash being hung in the usual way with balance weights, a strong cord is attached to each of its sides near the top in any secure manner. One method is to form a knot in the cord round a stout screw, which is secured to the sash, and the whole concealed by a plate of suitable form and material. The end of each cord passes over a pulley secured to the under side of the reveal of the window, and hangs down to a convenient height from the ground, finishing with a tassel or other ornament.—Patent completed.

917 W. R. Lake, Southampton-buildings. *Electro-magnetic machine.* (A communication.) Dated March 25, 1869.

This consists, first, in the union upon a single axis of rotation of a number of armatures of soft iron, with two branches having the form of an electro-magnet, but not magnetised. The parts which would form the poles (if these armatures were magnetised) are placed upon one and the same circumference of which they assume the curves. Secondly, in the union of a number of electro magnets (magnetised the first time from any suitable source) disposed exteriorly to the circumference described by the soft iron armatures, in such a manner that they are placed in a circumference concentric to the first and very near to the same. It results from this double arrangement that at each turn of the axis of rotation, each one of the soft iron armatures will pass before all the poles of the fixed interior electro-magnets, and that electric currents will be developed.—Patent completed.

918 T. Sowden and J. Newton, Leeds. *Bobbins.* Dated March 25, 1869.

The object is to obtain the requisite drag without subjecting the spindle to lateral pressure by the bobbin. This is effected by placing at the bottom of each bobbin a plate or collar of soft iron and supporting the bobbin on a small magnet, either a simple steel magnet of the ordinary horse-shoe form, or upon pieces of iron rendered magnetic by contact with a steel magnet or an electro-magnet suitably attached to them.—Patent completed.

919 H. A. Bonneville, Sackville-street. *Electric clock.* (A communication.) Dated March 25, 1869.

This consists, chiefly, in forming and breaking the connection with the positive and negative poles of a battery, by means of a vibrating bar operated by the pendulum, arranged and operating in a peculiar manner.—Patent completed.

920 A. C. Kirk, Glasgow. *Cooling liquids.* Dated March 27, 1869.

This consists in injecting the liquid to be cooled directly into the cold compartment of the apparatus, and in injecting the liquid used for removing the heat produced during compression of the air directly into the hot compartment, by which means the extensive and elaborate surfaces hitherto used interposed between the liquids and the air are dispensed with.—Patent completed.

921 This application for patent is still under the consideration of her Majesty's Attorney General.

922 H. Downie and I. B. Harris, Edinburgh. *Horse-shoes.* Dated March 27, 1869.

The metal portion of each shoe is made in one piece, and indiarubber or other elastic or flexible materials is so fitted or combined therewith that it projects slightly beyond the metal or treading surface.—Patent completed.

923 W. E. Gedge, Wellington-street, Strand. *Match box.* (A communication.) Dated March 27, 1869.

The match box is constructed of metal, wood, cardboard, or any suitable material, and may have a cylindrical square, rectangular, oval, or any shaped body made by soldering, clasping, stamping or otherwise. The bottom and the lid are formed of two similar pieces, each acting indifferently as bottom or lid, and are connected together by a piece of indiarubber or by any kind of spring.—Patent abandoned.

924 G. Dymond, Birmingham. *Baking powder.* Dated March 27, 1869.

The inventor takes acid or superphosphate of lime together with bicarbonate of soda or potash. In order to neutralise the deliquescent property of the acid phosphate of lime, he mixes it with starch or other farinaceous matter. One part of the said phosphate of lime to two parts of starch or farina answers well in practice. He mixes the starch or farina and phosphate of lime with carbonate of soda or potash in the proportion of two

parts of the mixture to one part of carbonate of soda or potash.—Patent abandoned.

925 L. Hannart, Charles-street, Clerkenwell. *Muzzle for quadrupeds.* Dated March 27, 1869.

The muzzle is composed of a head-dress made partly of an elastic tissue or flexible material and partly of a non-elastic tissue or material, elastic transversely and non-elastic lengthwise. A piece of steel proceeds from the end of the head-dress and extends along the upper part of the animal's head, is bent at the extremity of the nose, and ends under the lower jaw, intersecting the front of the animal's snout in two equal parts. Two other pieces of steel proceed also from the end of the head-dress and are fastened to it, and extend along each side of the animal's head under the ears ending with two small balls placed in a line with the animal's teeth.—Patent abandoned.

926 G. Hodgson, Bradford, H. Bottomley, Low Moor, and E. Cockroft, Odsall Moor. *Looms.* Dated March 27, 1869.

The boxes at each end of the batten are affixed to a common axis, which is supported to rock in bearings carried by the batten or going parts, and has applied to it an arm which by connecting rod and pin joints is attached to one end of an elastic ended lever, the other end of which is by connecting rod and pin joints connected to a frame or fork applied to a rocking arm or lever with means of adjustment as to position for variations of distance of motion obtained. This frame or fork receives and is actuated by a cam or tappet on the tappet or other suitable shaft. Each arm of the elastic-ended lever referred to is formed in two parts hinged together with the part of one arm or one end of the lever capable of turning on its hinge joint in the opposite direction to that of the other.—Patent completed.

927 J. J. Bagshawe, Sheffield. *Manufacturing semolina.* Dated March 27, 1869.

The machine is composed of a series of circular discs or cylinders of steel or other metal, which are fastened on a central shaft or spindle, thus forming a roller of any desired length and diameter.—Patent abandoned.

928 N. Voice, Handcross. *Greenhouses.* Dated March 27, 1869.

This relates to the opening and closing of the ventilating apparatus in greenhouses and other like buildings. This ventilating apparatus consists of hinged glazed frames and the inventor regulates the opening and closing of the same in the following manner. He carries a horizontal bar through the mullions for the length of the glazed frames, and at each mullion he fits a rack which is connected to the glazed frame. On the horizontal bar is a cogwheel to gear into each rack, and near the outer end of the bar is an additional cog-wheel provided with a stop or catch. The horizontal bar is fitted with a crank handle or other appliance for rotating it. When it is desired to open or close the glazed frames the catch is disengaged from its cog wheel and the horizontal bar is then rotated so that the other cog-wheels act upon the racks, and, therefore, open or close the frames according to the direction in which the bar is rotated. When the glazed frames have been moved into the required position the catch is allowed to take into its cog-wheel, so that the parts are all held.—Patent completed.

929 H. Haschke, Watling-street, E.C. *Breech-loaders.* (A communication.) Dated March 27, 1869.

The head of a screw or bolt (with its ring) forms the pivot of the trigger guard, and by its removal the trigger guard and all the mechanism can be taken out without the aid of a tool. The head of the screw forms the pivot of the extractor; the trigger guard acts as a lever and moves all the mechanism. A bottom or projection forms a lock to the trigger guard, a screw is used for helping to fix the butt, and there is a hole for the screw which holds the obdurator and the striker to the trigger guard lever. A part of the trigger guard serves to cock the striker and prevent it acting before the arm is quite closed. Another part of the trigger guard causes the extractor to act by the movement of the lever. A projecting part of the spring of the extractor gives a sharp blow to the latter, when it is released by the movement of the trigger guard. The spring may, however, be dispensed with, as the part of the trigger guard has been found to be sufficient to give the necessary blow to the extractor. The transverse screw attaches the tail of the guard to the breech box. There is a hole through which the head of the striker strikes the cartridge, and a piece or hood covers the striker in order to protect the shooter from accident in case the priming should burst.—Patent completed.

930 D. Jones, Birmingham. *Buckets and pails.* Dated March 27, 1869.

The inventor takes a blank or flat piece of sheet iron and stamps or raises it to a required contour in section in the ordinary manner, and then introduces a ring of wire upon the inside of the flange or rim of the lid or cover to serve the purpose of a mandrel or core in the formation of the shoulder or bead upon the outside of the flange or rim, which is effected by means of the action of a lathe.—Patent abandoned.

931 F. Parker, Leeds. *Locomotives.* Dated March 27, 1869.

This consists in arranging two steam cylinders in the centre line of the engine, the one in front and the other behind the gripping wheels, and connecting the piston rod of the one cylinder to two cranks on the two gripping wheels nearest to it, such two cranks being arranged at or about right angles to two other cranks on the other two gripping wheels, to which they are coupled with two pair of coupling rods, and to which last named cranks the piston rod of the other cylinder is connected. By this arrangement when the piston of the one cylinder is at the end stroke, the other will be at or about half stroke, and therefore by the coupling of the gripping wheels the engine that is for the time being at or about half stroke will be enabled readily to assist the other engine which is at end over the dead centres.—Patent completed.

932 J. Jaquillard, Genoa. *Musical boxes.* (A communication.) Dated March 27, 1869.

The inventor changes the position of the cylinder or barrel by means of a winch handle keyed to a vertical shaft, provided with a lever projection for acting on the teeth of a ratchet wheel having the same number of teeth as there are airs in the instrument. The teeth of this ratchet wheel gear with a second ratchet formed on the snail or cam usually employed to shift the cylinder.—Patent abandoned.

933 B. J. B. Mills, Southampton-buildings. *Extraction of oleaginous matter.* (A communication.) Dated March 27, 1869.

The apparatus in its most approved form consists of a high vat to contain the meal or other material, through which bisulphide of carbon is caused to ascend carrying the oil with it. A receiver, located beneath or below the said vat, communicating with the latter in such a manner that the matter divested of its oil may be readily and instantaneously discharged to leave the vat ready for a new charge and appliances to assist the vaporisation and complete removal of any bisulphide of carbon remaining in the meal after the latter has been divested of oil.—Patent completed.

934 J. W. Girdlestone, Norfolk-street, Strand. *Constructing vessels to avoid compass deviation.* Dated March 27, 1869.

This invention relates to a novel method of correcting and preventing compass dievations in iron, steel, or composite ships or vessels by polarising on a regulated system such parts of the ships or vessels as may be requisite, and by the simultaneous employment in some cases of soft iron.—Patent completed.

935 E. H. Hirch, Brunswick. *Preserving provisions on ships.* Dated March 27, 1869.

This invention has for its object an adaptation of the cooling machine described in the specification of a patent granted to Windhausen on March 5, 1869 (No. 669). Windhausen's air cooling machine is erected on board the ship, and so arranged that it may be driven from the ship's engines. Loading or storing rooms for the meat or other articles of food are also constructed on board the ship, they are made with double walls or sides which should be airtight, and the spaces between the double sides may be filled with non-conducting material or left vacant. Pipes are led from the air cooling apparatus into the loading or storing rooms to convey into the rooms the cold air from the cooling machine, and also to draw out of the rooms the air which has become partially warmed by absorption of heat from the contents of the rooms. In this way the meat or other articles of food may be kept at so low a temperature as to remain unchanged during a voyage of any length.—Patent completed.

936 W. Riddell and T. Bletcher, Bishopsgate-street. *Sewing machines.* Dated March 27, 1869.

This consists, first, in the peculiar devices for operating the vibrating hook in a machine for making what is called a chain stitch. The invention consists secondly, in the peculiar construction of a rotating hook for a chain stitch machine; and, third, in the peculiar means whereby the same machine can be adjusted to form the "chain stitch." The invention, consists fourth, in the novel devices for producing the reciprocating action of the needle bar. Fifth, in a novel method of supporting and securing the shuttle of a lock stitch machine, and, sixth, in constructing the cloth plates and also the front plate, which covers the needle bar, of materials not hitherto used for such purpose, which materials render the said plates superior in cleanliness and less costly of manufacture than the ordinary metal plates, and diminish the noise made by the machine in working.—Patent completed.

937 F. B. Taylor, Glasgow. *Counting machine.* Dated March 29, 1869.

The improved machine or apparatus which constitutes this invention is intended for counting and recording or registering numbers. It operates or is operated in a peculiar manner, and is formed and constructed as described in a provisional specification thereof dated March 29, 1869, No. 937.—Patent completed.

938 G. Bloem, Dusseldorf, and E. Scheidt, New York. *Breechloaders.* Dated March 29, 1869.

To the breech end of the barrel of the gun is fixed a cylindrical chamber or shoe to receive a bolt or movable breech-piece, which is capable of being moved to and fro therein by means of a handle or knob fixed thereto, the cylindrical chamber or shoe being formed with a suitable opening to receive the cartridge when the movable breech piece or bolt is moved back so as to leave the breech end of the barrel open. This cylindrical chamber or shoe is also formed with a suitable slot or opening to permit of the to-and-fro motion of the bolt or movable breech piece, and to hold it in either position as required, the knob or handle coming against suitable stops for this purpose.—Patent completed.

939 W. R. Lake, Southampton-buildings, Chancery-lane. *Soda and potash.* (A communication.) Dated March 29, 1869.

This invention is based upon, first, the known decomposition of chloride of sodium and chloride of potassium by the oxide of lead in the presence of water at the ordinary temperature. By this decomposition is formed, on the one hand an oxychloride of lead, or, more correctly peaking, a mixture of chloride of lead and hydrate of oxide of lead (solid), and on the other hand caustic potash or soda, which remains in solution. This solution separated from the solid part is evaporated to withdraw from it the soda or potash. Second, the addition of lime which produces a remarkable increase in the production of potash and soda hitherto unknown.—Patent completed.

940 W. R. Lake, Southampton-buildings, Chancery-lane. *Blowing apparatus.* (A communication.) Dated March 29, 1869.

In the invention the periphery of the blower case, instead of being made integral with the side plates, is made of separate sections, which at their sides are fitted between the side plates, and are bolted thereunto and abut with their ends against each other.—Patent completed.

941 W. R. Lake, Southampton-buildings. *Horse-shoe nails.* (A communication.) Dated March 29, 1869.

The process consists first in reducing in grooved rolls soft tough wrought-iron from the form of bars into strips of any desired length or width. Next, the inventor submits the material to the action of punching dies. The blanks are then submitted to the action of a rolling machine, which forms part of this invention, by which machine the shanks of the blanks are elongated. Then the elongated blanks are compressed at the point by a punch or plunger acting against a solid bed so as to bevel the point ends across.—Patent completed.

942 E. Morewood, Rock Cottage, Glamorganshire. *Coating metals.* Dated March 29, 1869.

When coating sheets of iron or other metal with tin or terne metal or other readily fusible metal, the inventor removes the plates from a bath of the coating metal through a pair of rollers placed in contact with the molten coating metal, but with their nip or line of contact above it. On the outer sides of the rollers, and resting on the molten metal, grease or flux is placed so as to rise by preference nearly to the top of the rollers; but the grease or flux is not allowed to pass between the rollers, the rollers themselves stopping it back, and there are suitable guards or partitions at their ends.—Patent completed.

943 S. Firth, Leeds. *Cutting coal.* Dated March 29, 1869.

This consists in making a boss on that part of the pick nearest the point. In this boss is a socket of any suitable shape. By preference the inventor uses a circular taper socket, the loose point being cottered into the socket against a piece of india-rubber or other suitable substance at the bottom of the socket or around the outer edge of the socket, so that, when the blow is given, some part of the strain is taken off the point. The edge of the socket is brought as close as possible to the point, for, as the socket must enter the groove made in the coal, and must be clear of the top and bottom of the groove, and as, in some cases, the groove is not more than 1½in. in height, it will be readily seen that the closer the socket is to the point the greater the resisting strength of the point.—Patent completed.

944 A. Clark, Chancery-lane. *Stereoscopes.* (A communication). Dated March 29, 1869.

This consists mainly in the use of magnets for receiving and holding the pictures in the proper position for being viewed. It also consists in binding the ends of the card pictures or views with iron or other suitable material to be acted upon by the magnets, and in the method of delivering a single card or picture to the magnets and discharging it therefrom, by which arrangement any desired number of cards or pictures may be received and discharged from a revolving cylinder.—Patent completed.

945 W. P. Hope, Wouldham. *Cement kilns.* Dated March 29, 1869.

Instead of constructing the kilns of considerable height as hitherto, and open above, the inventor covers each with a firebrick arch, and causes the heat to pass through but a comparatively small thickness of the materials operated on. For each kiln he provides a chamber contiguous thereto, and capable of being placed in communication therewith through a suitable channel provided with a damper.—Patent abandoned.

946 G. T. Bousfield, Loughborough Park, Brixton. *Sewing machines.* (A communication.) Dated March 30, 1869.

The improvements consist, first, in a new form of hook; second, in an arrangement of the hook so that it revolves in planes perpendicular to the plane in which the needle reciprocates; third, in the employment of a case around the bobbin, whereby a thick bobbin containing in consequence much thread may be employed, and a tension be put upon the lower or bobbin thread; fourth, in the employment of a non-rotating support for the bobbin, said support being surrounded by the hook; fifth, in the combination with a rotating hook and a reciprocating needle of a take up or apparatus for pulling up the loop of needle thread when cast off by the revolving hook.—Patent completed.

947 The abstract of this specification will appear in a future number.

948 J. Bath, King William-street, E.C. *Telescopic pencils.* Dated March 30, 1869.

A helical spring is placed loosely within the pencil case and presses against the pencil holder for pushing the pencil out of the case. A spring catch holds the pencil within the case. When the pencil is pushed thereinto this spring is collapsed and the pencil pushed out.—Patent abandoned.

949 H. G. Dixon, Dundee. *Velocipedes.* Dated March 30, 1869.

The inventor forms those parts tubular which constitute the steering apparatus and those which connect the front and hind wheels together. That portion forming the steering apparatus consists, first, of the main tube screwed into a cross plate immediately above the periphery of the leading wheel; to the lower part of this tube the inventor attaches a second main tube which extends in a diagonal direction towards the periphery of the hinder wheel (or centre of the axle if two hinder wheels are used), where it is screwed into a cross plate similar to that of the first-named tube. The inventor connects one of the main tubes to the bearing of the front and the other to those of the hinder, wheel or wheels by smaller tubes screwed into or attached to the before-named cross-plates.—Patent abandoned.

950 W. W. Harris, St. John's Wood. *Velocipedes.* Dated March 30, 1869.

This consists of one or more toothed wheels, or other gearing, attached to the driving wheel and geared with one or more toothed wheels or other gearing attached to the crank in a manner somewhat similar to the arrangement known as the sun and planet wheel.—Patent abandoned.

951 A. Muir, Manchester. *Velocipedes.* Dated March 30, 1869.

This consists in making the saddle spring bar of such velocipedes adjustable in height so as to be available for any rider by the use and application of screws to the lower extremity of the back springs, which in the case of this invention pass loosely through holes formed at or near the junction of the main bar with the axle of the back wheel or wheels, and are secured at any height by lock-nuts.—Patent abandoned.

952 M. M'Leod, Edinburgh. *Railway.* Dated March 30, 1869.

The improvement consists in suspending or supporting a plate, plank, rail, rod, bar, rope or ropes, one or more of them, and working thereon, in or by suitable grooves or guides thereon, a carriage or machine having grooved or flanged wheels, and supplied on each side with suitable guide wheels when desired, and with adjustable or otherwise hanging seats or receptacles for passengers or goods, such seats or receptacles being preferably adjusted somewhat lower than the level of the rail.—Patent abandoned.

953 C. E. Brooman, Fleet-street. *Winding threads.* (A communication.) Dated March 30, 1869.

This consists in balling or winding threads so that the ball is unwound from the centre, although the thread proceeds from the outside. A needle is used which resembles a wool needle, the eye of which has been filed through,

When the ball is wound, the inner thread (or in some cases the outer thread) is drawn into the eye of the needle, which is then pressed into the ball at the inside and made to come out at its outside, drawing the inner thread with it. This thread is to be pulled when the ball is unwound. Modifications are described.—Patent abandoned.

954 A. Barclay, Kilmarnock. *Steam boilers.* Dated March 30, 1869.

This consists in making the space surrounding the boiler proper sufficiently large to receive a large number of tubes, which are connected at their lower ends to the water space and at their upper ends to an upper chamber. The water space of the boiler proper is provided with a large number of tubes, by means of which additional heating surface is obtained. From the upper part of the furnace a flue passes to the top of the chamber; this flue is provided with a damper, which may be opened or closed at will. The outer sets of tubes hereinbefore mentioned are surrounded with a casing, which may be either single or double, and when double it may be made to constitute an additional water space or an air space.—Patent completed.

955 J. Briggs and J. Almond, Blackburn. *Weaving looms.* Dated March 30, 1869.

Instead of tying up the healds directly to the top jacks, wires, or other lifters of the dobby, the inventors use longer cords, and change the direction of the same by means of small bowls or grooved pulleys, so as to bring the points of attachment of the cords much nearer to the ends of the healds.—Patent abandoned.

956 T. E. Williams, Newport. *Distilling hydro-carbon oils.* (A communication.) Dated March 30, 1869.

This consists chiefly in providing the still with means for alternately supplying and exhausting the oil, so that when the still is heated to the temperature required to vaporise all the distillable products, or so much thereof as may be desired, a succession of charges of the cold oils may be admitted, each of such charges being suddenly vaporised, and the evolved products successively removed. Also in making provision for a gradual condensation of the evolved products or so much thereof as may be desired, and in the means for producing a distillate, which may have in combination as many of the different chemical purposes resulting from the distillation as may be practicable or desirable.—Patent completed.

957 W. F. Proctor, Cheapside. *Sewing machine table* (A communication.) Dated March 30, 1869.

This relates to the mounting of a sewing machine upon a platform forming part of a sewing machine table top, which platform may be raised and dressed at pleasure, thus elevating the machine to the level for working or sinking it below that level and out of sight when not required for use.—Patent completed.

958 F. Bender, Manchester. *Railways.* Dated March 30, 1869.

The inventor forms notches across the ends of two rails to be joined, in which he places a piece formed with a T end on each side, and these T ends abut against the "fins" or other side of the rails.—Patent abandoned.

959 T. G. Webb, Manchester. *Glass furnaces.* Dated March 30, 1869.

The melting pots are placed upon the stage, and the firebars may be radial if desired. The walking stage may be opened or closed by a door, and there is an air trunk which may be regulated by a damper. An extension of the walking stage and a wall support a slab, on which is placed a plate, which in its turn supports a plate provided with a circular opening on which is placed a pipe, the latter portion fitting loosely on to the former.—Patent completed.

960 H. Y. D. Scott, Ealing. *Lime and other kilns.* Dated March 30, 1869.

The inventor arranges any convenient number of compartments in a series, side by side. Each compartment consists of three divisions, situated vertically over the other, and comprises, first, a cooling chamber at the bottom, into which the substances operated upon descend after their calcination, and whence they are finally withdrawn. Second, a middle chamber in which the substances to be operated upon are subjected to the egree of heat necessary for their calcination; and, third, a chamber in which these substances are subjected to a preparatory heating to expel moisture and raise them to a fitting temperature before they descend to the central chamber for calcination.—Patent completed.

961 W. E. Cadman, Holloway. *Decorating surfaces* Dated March 30, 1869.

This consists in backing up in close contact by means of any suitable material, transparent or otherwise, having a design or character printed, painted, or otherwise made thereon, transparent glass, globulous beads, or dust, or fragments of glass, or other transparent material, in such manner that the design or character shows through the transparent glass globules, and a crystalline effect suitable for decorative purposes is obtained.—Patent abandoned.

962 A. Chambers, Fairfield-road, Bow, E. *Manually propelled carriages.* Dated March 31, 1869.

The body of the vehicle is, by preference, suspended to springs carried by the main axle. In fixing the one driving wheel, it is placed freely upon the axle, to which a bar or bars is or are attached, and the end or ends of the said bar or bars is or are firmly secured to the rim or felloe of the driving wheel. In order that the vehicle may travel round curves or over uneven roads without twisting or straining the main shaft or axle, one only of the wheels is firmly fixed to the axle as described or otherwise; in order to enable either of the wheels to slip upon the axle as occasion may require, the rotary motion may be transmitted to the wheels by friction in such manner as to enable both to serve as driving wheels, and to allow either of them by slipping more or less upon the axle on encountering excessive resistance to rotate at a slower speed than the other without hoisting or straining the shaft or axle.—Patent completed.

963 B. Dobson and J. Eastham, Bolton. *Carding engines.* Dated March 31, 1869.

The inventors make use of the usual radial arm with a slot at the other end. In this slot are two slides, which are raised by a bowl or cam on the cam wheel and drawn down by the cam or by a spring. The upper end of the lower slide is provided with a serrated plate, and a second serrated plate is fixed to the upper slide. To the upper and lower sides of the ends of the top flat are fixed serrated plates; when the top flat is to be raised, the cam or bowl raises the lower slide and brings the lower serrated plate against the serrated plate at the lower side of the top flat, and when the top flat has been raised sufficiently, it brings the upper serrated plate of the top flat against the serrated plate of the upper slide.—Patent completed.

964 F. W. Follows and J. Bate, Manchester. *Lawn mowing machine.* Dated March 31, 1869.

This consists in an improved mode of giving motion to the knife barrel shaft of lawn mowing machines, for which purpose the inventors make in one of the travelling or supporting wheels an internal toothed gear, and on the same end of the knife-barrel shaft is keyed a small pinion which gears into and receives its motion from the internal gear or wheel in the travelling wheel. The same result may be obtained by friction rollers. By these means we are enabled to dispense with the back roller now required for giving motion to the knife barrel.—Patent completed.

965 T. A. Dillon, Dublin. *Utilising waste steam.* Dated March 31, 1869.

A bell-mouthed steam pipe leads from the side of the blast pipe to the firebox, where it is formed into a zigzag coil beneath the firebars, and terminates in some convenient part of the firebox or water tank. The pipe of which the coil under the firebars is formed is perforated with small holes alternating (that is to say, that no two steam jets shall be directly opposite each other) through which a portion of the waste steam rushes. The steam jets thus produced are caused by the arrangement of the coil to play partially on the firebars and partially into the fire, the effect whereof is first to abstract from and utilise the excessive heat of the firebars and keep them cool, thus preventing the accumulation and adherence of clinkers thereon. Second, the steam is thus forced into contact with the heated bars, the incandescent part of the fuel, and the carbonic oxide (which may be generated therefrom) is decomposed into its elements, and free hydrogen is liberated.—Patent completed.

966 T. Greenwood, Leeds, and J. Keats, Leek, Staffordshire. *Boots and shoes.* Dated March 31, 1869.

The front part of the boot upper is shaped in such a way as to provide two folding pieces, which act the part of gussets. The edges of these gussets are securely sewn to the "back quarter" of the "upper" in the lines, and to form an additional connection between the front part of the upper and the back quarter, elastic side pieces are applied to the boot, but these may be dispensed with if thought desirable. A strap or tongue, which is part of the back quarter or attached thereto, passes round the front of the boot to connect with a button or a buckle on the other side, and thereby close the upper part of the boot. By cutting the front part of the upper in one piece, and connecting it with the back quarter as explained, the inventors leave no vertical openings in the boot, and thus make it practically waterproof.—Patent completed.

967 A. F. Baird, Pimlico. *Earth closets and urinals* Dated March 31, 1869.

A light iron framing, which should be of ⅜in. round iron with a piece of wood fixed to one end, is hung in brackets secured to the framing. In front of the hopper, from a crossbar in the front part of the frame, a small bar is swung, the end of which hangs a little below the rail of the framing, up to which the weighted part of the valve rises, and, as the latter rises, it strikes up this bar, which causes the wood at back of hopper to strike the latter briskly, which never fails to agitate the earth even when it has stood forty-eight hours, and thus settled down nearly 2in. When the weighted end of the valve falls, the frame and striker also fall of their own weight ready for other use.—Patent completed.

968 R. Johnson, Waterloo-place, Pall Mall. *Continuous bar fences.* Dated March 31, 1869.

The inventor makes the standards of continuous bar or strained wire fences of a bar of iron with a flange or flanges so that it shall somewhat in section resemble the letter L or T, or a double or single fish hook; or he otherwise forms the bar with a flange or flanges so that, after the horizontal wires or bars of the fence have been passed through holes in the stems of the standards, keys or wedges may be driven down vertically between the horizontal bars or wires of the fence and the flange or flanges of the standards.—Patent completed.

969 G. Wells, Westminster. *Separating copper and bismuth.* Dated March 31, 1869.

The ore is first reduced to an impalpable powder mixed with a given quantity of saltpetre. It is then placed in shallow pans supplied with a hood to retain the vapour arising therefrom, heat is applied under the pans, the temperature not being raised above 300deg. Fahr., and, when the ore is well heated, a small quantity of water or steam is introduced so as to keep the surface of the ore covered with vapour. The ore is kept continually stirred, atmospheric air being freely admitted thereto, by which means the sulphur is converted into sulphuric acid, which unites with the copper in the ore and converts it into a soluble sulphate.—Patent completed.

970 J. H. Lloyd, Llangefin, Anglesey. *Working, cutting, and shaping tools.* (A communication.) Dated March 31, 1869.

In sawing small or large stones, either in one block or several together, the inventor employs endless metallic bands without teeth and moved by revolving wheels or drums of any diameter required, as hereinafter described. The chiselling or dressing of the stones is performed by a tool or tools in a heavy hammer block or tool holder, the weight and fall of which is regulated as required, the stone or stones being held on a movable platform and moved by mechanical arrangements in all directions to meet the blows of the hammer.—Patent completed.

971 H. Davey, John-street, Adelphi. *Hydraulic machinery.* Dated March 31, 1869.

This invention chiefly consists in a valve which is in two parts, and is provided with a collar of leather or other suitable material covering the point of junction of these two parts. This valve is designed for an ordinary simple hydraulic crane or engine.—Patent completed.

972 W. Langer, Whitechapel-road. *Manufacture of cigars.* Dated March 31, 1869.

This consists in forming or shaping the inside or "bunches" of cigars by placing them in moulds or shapes of the size or sizes of the cigars to be made, and in filling or building up the tobacco in the moulds.—Patent abandoned.

973 B. J. B. Mills, Southampton-buildings, Chancery-lane. *Envelopes.* (A communication.) Dated March 31, 1869.

A band or border is formed on or fixed to one edge of the envelope, and at the opposite edge the envelope is perforated or pierced through both the front and back in a line at a suitable distance from the edge thereof.—Patent completed.

974 T. Corbett, Shrewsbury. *Carts, waggons, and drays* Dated March 31, 1869.

The inventor forms at or near the inner end of each of the arms or parts of the cranked axle upon which the naves of the wheels turn, a strong upright rod. Each of these upright rods are in a line with the vertical part of the cranked axle, and parallel with the side of the body of the cart. On each side of the body of the cart an eye or ring is fixed, which eyes or rings work upon the upright rods of the axle. Around these rods strong coiled springs are placed, their upper ends bearing against the eyes or rings on the body of the cart, and their lower ends bearing against the arms of the axle.—Patent abandoned.

975 B. and H. Craven, Sheffield, and J. N. Craven, York. *Brick and tile pressing machine.* Dated March 31, 1869.

Upon a suitable rectangular framework the inventors mount standards which support an overhead steam cylinder, to the lower end of the piston rod of which is affixed a platten or plunger of a form suitable to the shape and size of the brick or tile to be pressed. Between the sides of the frame, and at or near the top of the same, is a sliding table upon which are fixed two moulds, one near either end of the table. A rack is formed on or affixed to the under side of the table, into which rack is geared a tooth sector, secured to a shaft which has a motion of partial rotation in the frame. On the outer end of the shaft are affixed curved wings or levers, which are acted upon alternately by a reciprocating clutch mounted upon the lower end of a vertical rod affixed to a crosshead carried by the piston rod of the cylinder.—Patent completed.

976 J. Livesey, Victoria Chambers, S.W. *Permanent way.* Dated March 31, 1869.

This consists in making the fish plates of greater vertical depth from simple rolled bars for the purpose of increasing the strength and power of resistance to vertical deflection in the joint. The fish plates are made to project downwards to any required extent below the bottom of the rail, and are rolled into a suitable form at the lower part. A cotter may be driven through both plates immediately underneath the joint if required. The invention consists, second, in the construction of wrought-iron sleepers formed by bending plates into the form of saddles with tiebars passing through each side.—Patent completed.

977 J. A. and J. Hopkinson, jun., Huddersfield. *Steam engine indicators.* Dated March 31, 1869.

An arm or pencil holder is fixed upon the top of the ordinary piston rod of the indicator, which arm turns on a swivel centre, and at a lower point there is fixed a swivel guiding arm, which is so formed as to admit of a drop guiding rod passing through it so that by turning the swivel arm the pencil can be brought upon the paper, which is usually fixed on the revolving barrel, thereby facilitating the taking of diagrams.—Patent completed.

978 R. Jones, Botolph-lane. *Preserving food.* Dated March 31, 1869.

The cases (usually formed of tin) containing the matters to be preserved, are attached each by a small pipe having a tap in it to suitable exhaust apparatus, in order that as desired a vacuum or partial vacuum may be created in the cases through the pipes connecting them with the exhaust apparatus. The cases thus arranged in respect of the vacuum apparatus are also placed in a bath of boiling water, when the tap in each pipe from a case to the exhaust apparatus is turned so as to admit of free passage between the interior of each case and the exhaust apparatus for (say) one or two minutes, by which the air contained in the cases will be withdrawn therefrom, and wholly or in part from the contained substances, thus getting clear of the greater portion of the decomposing or destructive element in the substances to be preserved before the cooking thereof begins.—Patent completed.

979 W. E. Gedge, Wellington-street, Strand, W.C. *Belt buckles.* Dated March 31, 1869.

This fastening is made of tinned iron or other suitable material. It is formed of a plane part riveted at each angle at the points to one of the ends of the belt. On this part, and of one piece with it, rises the buckle properly so called having a sloping shape. This piece having to receive the wedge which is to fix the free end of the belt is so made that the three faces of its upper part present a development insensibly diminishing down to its base, thus its top as well as the sides each presents a greater breadth than the corresponding part of its base.—Patent completed.

980 J. B. Gridley, Ingram-court, Fenchurch-street. *Paper pulp.* (A communication.) Dated March 31, 1869.

This invention is based upon the discovery that the entire stalk (the fibrous and ligneous portions and pith) of the okra plant (Hibiscus Esculentus) can be applied to the production of pulp suitable for the manufacture of paper and papier mache of the various quantities in demand, and that this plant also yields the matter suitable for sizing the paper.—Patent abandoned.

APPLICATIONS FOR LETTERS PATENT.

Dated October 12, 1869.

2958 A. B. Childs, Mark-lane, Middlesex. An improved process for reducing wood to a fibrous condition for the manufacture of paper stuff or pulp.

2959 E. A. Snuggs, Sheet-street, Windsor, Berks. Improvements in cocks, taps, and valves.

2960 R. L. Hattersley and J. Hill, Keighley, Yorkshire. Improvements in looms for weaving.

2961 T. Cope, J. Hignett, and G. Lander, Liverpool. Improvements in machinery for twisting or spinning tobacco.

2962 J. B. Blythe, London-street, City. Improvements in the mode of, and apparatus for, vaporising and burning liquid hydrocarbons for the production of heat in furnaces and for generating steam.

2963 M. Andrews, Birmingham. Improvements in locks and latches.

2964 W. Bennett, Aston, near Birmingham, and J. Currall, Birmingham. Improvements in kitchen ranges.

2965 E. Farrington, Grande Rue Passy, Paris. Improvements in breech-loading firearms.

2966 E. Brown, Lyme Regis, Dorsetshire. An improvement in the mode of propelling carriages, boats, and other vehicles by the hands or feet.

2967 J. Morrison and J. Thomas, Ferry Hill Ironworks, Durham. Improvements in the fireplace and grate of puddling furnaces, mill furnaces, and other reverberatory and boiler grate furnaces.

2968 T. Stevenson, George-street, Edinburgh. Improvements in iron girders.

2969 W. Lincolne, Glasgow. Improvements in fastening or securing the joints of belts, and in the means employed therefor.

Dated October 13, 1869.

2970 J. H. Selwyn, Woodland Crag, Grasmere, Westmoreland. Improvements in firearms, parts of which are applicable for use as a digging tool.

2971 J. Halford, Brettel-lane, Kingswinford, Staffordshire. Improvements in puddling furnaces used in the manufacture of iron, and in other reverberatory furnaces.

2972 L. M. Casella, Hatton-garden, Middlesex. An improved apparatus to be employed in lighting gas burners, lamps, and other articles.

2973 J. Smith, Cockspur-street, Charing Cross. Improvements in instruments for timing ships' logs.

2974 J. Kennedy, Westminster. An improved sanitary composition or cement for building and ornamenting purposes.

2975 R. Scholefield, Leeds. Improvements in pumps or apparatus for raising or forcing water or other liquids or fluids, and for transmitting the motive power thereof.

2976 T. Parry, Balham, Surrey, and J. M'Hardy, Edinburgh. An improved drag, applicable to waggons, omnibuses, and other wheeled vehicles.

2977 S. Osborn, Sheffield. Improvements relating to knife bars and knives for reaping and mowing machines.

2978 W. Challiner, Winco-road, Grimesthorpe, Sheffield. Improvements in the manufacture of forks and spoons.

2979 C. Brakell, North Moor Foundry, Oldham. Improvements in fans, pumps, and machinery for propelling air, fluids, and other substances by centrifugal force.

2980 J. Hartley, Leeds. Improvements in apparatus for registering billiards or other games.

2981 R. J. Ellis, Castle-street, Liverpool. Improvements in apparatus for desiccating animal and vegetable matters.

Dated October 14, 1869.

2982 W. J. Bonser, Highbury New Park, Middlesex. Improvements in apparatus to be used for feeding and watering cattle in railway trucks.

2983 W. E. Gedge, Wellington-street, Strand. A novel mode of putting up or incasing packets of needles.

2984 J. H. Roberts and E. Simons, Manchester. Improvements in brakes for railway carriages.

2985 B. Calvert, Bolton, Lancashire. A machine for cleaning hose pipe used for fire engines and other purposes.

2986 F. M. Cotton, Foulis-terrace, Brompton, Middlesex, and W. Field, Lower Tooting, Surrey. Improvements in apparatus for facilitating the copying of drawings and other representations, forms, or designs.

2987 S. Wilson, Manchester. Improvements in applying power to the knee-joint levers of certain presses used in pressing cotton, and suitable for other materials.

2988 C. W. Siemens, Great George-street, Westminster. Improvements in smelting iron and steel, and in apparatus and furnaces employed in connection therewith.

2989 L. A. Lesage, Rue Ste. Appoline, Paris. Improvements in closing and securing vessels containing alimentary substances.

2990 E. Lane, Paddington, Middlesex. Improvements in parts of the permanent way of railways.

2991 C. L. Page, Westminster. Improvements in packing cases or boxes for containing bottles or other articles.

2992 J., J., and C. Hudson, Newcastle-upon-Tyne. Improvements in machinery for the manufacture of paper.

2993 W. Kloen, Birmingham. A new or improved method of water colour printing.

2994 E. L. Parker, Birmingham. A new or improved combined pocket corkscrew and carriage key.

2995 J. Taft and J. C. Edwards, Manchester. Improvements in machinery for opening, cleaning, and preparing cotton and other fibrous materials.

2996 W. Barbour, Glasgow. Improvements in the arrangement of stage lights, and in shades for covering or protecting the same.

2997 N. Washburn, Massachusetts, U.S.A. Having reference to railway carriage wheels.

2998 W. Avery and A. Fenton, Redditch, Worcestershire. Improvements in cases or receptacles for needles, pins, matches, pens, cards, stamps, photographs, cotton, and other similar articles.

2999 E. Roe, Popham-street, Nottingham. Improvements and additions in or to machinery or apparatus for the manufacture of looped or knitted fabrics, and also of warp and weft fabrics.

Dated October 15, 1869.

3000 G. W. Bowley, Addle-street, City. An improved ladies' and children's combined under garment.

3001 D. Brown, Clerkenwell Green, Middlesex. An improved method of treating iron and other metal surfaces, so as to render the same better adapted to advertising and other purposes.

3002 L. Byrne and W. Payne, Birmingham. An improved packing applicable for buckets, pistons, and stuffing boxes, and for all other purposes where packing is employed.

3003 J. Mackie, St. James'-street, Westminster. An improvement or improvements in lock fast breech-loading firearms.

3004 W. R. Lake, Southampton-buildings, Chancery-lane. An improved machine for drilling or boring rocks, chiefly designed for working mines, tunnels, and quarries, and for submarine operations.

3005 W. R. Lake, Southampton-buildings, Chancery-lane. Improvements in sewing machines.

3006 W. R. Lake, Southampton-buildings, Chancery-lane. Improvements in chain cable stoppers.

3007 S. Barber, Liverpool. Improvements in the propulsion and steering of navigable vessels.

3008 J. Walker, Glasgow. Improvements in apparatus for measuring fluids.

3009 J. W. Robinson and T. Murray, Glasgow. Improvements in the burning of liquid carbons, as the tarry residues left in the refining of mineral oils, as a fuel in furnaces, and in the construction and arrangement of apparatus and furnaces therefor.

3010 E. T. Hughes, Chancery-lane. Improvements in means and apparatus for regulating or controlling the delivery of tickets at railway stations and other similar places, part of which improvements is applicable to telegraphic purposes.

3011 E. T. Hughes, Chancery-lane. An improved lift for raising and lowering merchandise and weights of all descriptions.

3012 W. B. Leachman and J. Holroyd, Leeds. Improvements in hydraulic apparatus for raising and forcing water.

3013 H. Smith, Henrietta-street, Covent-garden. Improvements in dish covers, and in the manufacture of the same.

3014 J. H. Lyon, Sutton, Lancashire, and W. Lyon, Runcorn, Cheshire. Improvements in furnaces for making glass.

3015 W. E. Gedge, Wellington-street, Strand. An improved elastic horseshoe.

3016 A. H. Douche, Boulevart Bonne-Nouvelle, Paris. Apparatus termed Douche's regulating valves, for regulating the supply of water to turbines and hydraulic wheels.

3017 H. M. Marsden, Sheffield. An improved method of manufacturing sheep shears and other articles of cutlery.

Dated October 16, 1869.

3018 J. Horton, Milverton, near Leamington, Warwickshire. Improvements in castors for furniture.

3019 F. F. Whitehurst, Cambridge-terrace, Richmond-road, Putney, Surrey. Improvements in apparatus and machinery for mashing grain and obtaining products therefrom.

3020 J. Willats, Kingsland-road, Middlesex. Improvements in playing cards.

3021 J. J. Nancy, Hatton-garden, Middlesex. Improved holders for supplying thread to sewing and embroidering machines, and apparatus for filling such holders.

3022 A. Angell, Banbury, Oxfordshire, and J. J. Perry, Red Lion-square, Middlesex. Improvements in machinery or apparatus for heating and delivering metal bars.

3023 W. H. H. M'Neight, Dublin. Improvements in venetian and other blinds.

3024 J. Raper, Dudley Hill, near Bradford, and M. Pearson and D. Mills, Bradford, Yorkshire. Improvements in looms for weaving.

3325 J. Player, Philadelphia, Pennsylvania, U.S.A. Improvements in the manufacture of iron and steel.

Dated October 18, 1869.

3026 W. Rogers and G. Tidcombe, Watford, Hertfordshire. Improvements in the manufacture of balls and mallets used in the game of croquet and other games, and in apparatus employed therein.

3027 N. Hodgson, New Barnet, Hertfordshire. A motive power engine.

3028 J. M. A. Stroh, Tolmers-square, Hampstead-road, Middlesex. Improvements in electro-magnetic clocks, part of which improvements are applicable to mechanical clocks.

3029 G. Collins, Preston, Lancashire. Improvements in carding engines.

3030 J. C. Martin, Gray's Inn-road, Middlesex. Iron or other metal name plates for shop window stall plates, door plates, &c.

3031 J. and W. Bottomley, Bramley, near Leeds. Improvements in machinery for fulling or milling woollen and other woven or felted fabrics.

3032 J. and W. Bottomley, Bramley, near Leeds. Improvements in machinery for washing and scouring woollen and other woven or felted fabrics.

3033 P. Jacques, Rue Turgot, Paris. An improved process for purifying and decolouring blood albumen.

3034 C. and W. Bradley and E. Thackray, Bradford, Yorkshire. Improvements in wool-combing machinery.

3035 R. S. Bartleet, Redditch, Worcestershire. Improvements in cases for the holding of needles and other articles.

3036 A. P. Price, Lincoln's Inn-fields. Improvements in the purification of coal gas.

3037 M. Ker, Mansfield-road, St. Pancras, Middlesex. Improvements in hanging and drawing window and other curtains.

3038 C. E. Spagnoletti, Telegraph Department, Great Western Railway, Paddington, Middlesex. Improvements in apparatus for signalling by means of electricity.

3039 A. Welch, Southall, Middlesex. Improvements in cattle trucks.

3040 A. V. Newton, Chancery-lane. Improvements in fabrics to be used as a sacking for bedsteads and couches, and in frames for supporting the same at tension.

3041 W. R. Lake, Southampton-buildings, Chancery-lane. An improved nut for screw bolts.

Notice.—Having received communications from persons residing in the country to the effect that difficulties are occasionally experienced by them in obtaining copies of printed specification from the Patent Office, in consequence of the varying nature of the postage thereon, our readers are informed that upon receipt from them of particulars of the specifications they require, together with a remittance for the cost and approximate postage thereof, we shall be happy to procure and forward such specifications free of all further charge. Sums under Five Shillings may be remitted in postage stamps, for sums above that amount a Post Office Money Order should be sent, payable to Robertson, Brooman, and Co., Patent Department, 166, Fleet-street, London, E.C., to whom all communications upon the subject should be addressed.

THE

MECHANICS' MAGAZINE.

LONDON: FRIDAY, OCTOBER 29, 1869.

THE METROPOLITAN MAIN DRAINAGE AND ITS WORKING.

THE most important of the numerous important improvements undertaken by the Metropolitan Board of Works is undoubtedly the main drainage of the metropolis. With the exception of a portion of one of the main lines of sewer, the system has been in operation about four years. The uncompleted sewer is the low-level line on the north side of the river, portions of which have been delayed in consequence of their having to be formed in connection with the Thames Embankment, between Westminster and Blackfriars, and also with the embankment of the river at Chelsea. The principal portion of the system, however, having been so long in operation, an opportunity is afforded of considering the effect which it has produced upon the health of the metropolis. But before proceeding to this part of the subject, we will notice what progress has been made in the works generally during the past twelve months or so. From the annual report of the Metropolitan Board of Works, which has recently been issued, we find that about four miles of the low-level sewer between Tower-hill and the Pumping Station at Abbey Mills have been completed and are in operation. A further portion, rather more than a mile in length, has been formed under the Thames Embankment, and the western portion of the sewer, to a length of more than 3½ miles between Hammersmith and the temporary pumping station at Cremorne, has for some time been in operation. Of the remainder, a further part, between the Temple Gardens and St. Andrew's-hill, is in course of construction under the Thames Embankment. From St. Andrew's-hill to New Earl-street the sewer is to be constructed by the Metropolitan District Railway Company in connection with their works, and it had also been intended to construct the portion between New Earl-street and Tower-hill in connection with the railway. But as it was uncertain when that part of the line would be formed, the Board wisely determined to forego the advantages offered by a joint execution of the two works rather than delay the construction of the sewer; for until this part is complete, the other portions westward cannot be made available. The Board, therefore, accepted the tender of Mr. W. Webster for the construction of the sewer between New Earl-street and Tower-hill for the sum of £67,500.

It has also been decided to proceed with the formation of that part of the sewer between Westminster Bridge and Chelsea Suspension Bridge, at which point it is proposed to erect the pumping station to lift the sewage from the low-lying western districts. The Board accordingly accepted the tender of Messrs. Hiscox and Williams for the construction of these works for the sum of £72,700. When these portions of the sewer are completed, the drainage of the whole of the low-level area, east of Chelsea Bridge, will be intercepted from the river and conveyed to the outlet at Barking Creek. The only portion of the Low-Level Sewer which will then remain to be formed will be that between Chelsea Bridge and Cremorne, which will be constructed in connection with the Chelsea Embankment.

One of the principal features in the Main Drainage scheme is the splendid Pumping Station at Abbey Mills, West Ham, which is the largest establishment of the kind in existence. This came into operation during the past year, having been formally opened by the Board on July 30, 1868. The sewage is there pumped from the Low-Level Sewer into the Outfall Sewer, a height of 36ft., by eight engines, together of 1,140 nominal horse power. The buildings were erected by Mr. W. Webster, the cost of the whole having been £218,300. The eight engines and machinery were constructed and erected by Messrs. Rothwell and Co., at a total cost of about £61,000. A detailed description of the pumping station, engines and machinery, and of all the arrangements connected therewith, will be found in the MECHANICS' MAGAZINE for August 7, 14, 21, and 28, 1868. The total cost of the Main Drainage works up to June 30 last had been about £4,128,000.

Having then seen the general position of this great undertaking, let us now glance at the effect produced by it on the public health. A reference to the tables given in the Registrar General's reports shows that the deaths in the metropolis, especially in the low-lying districts, have been fewer since the execution of the Main Drainage Works than in previous years, which may be considered evidence of the improved sanitary conditions which now prevail in consequence of those works. In districts which are lower than the level of the river at high water, the contents of the sewers used formerly to stagnate during a large portion of each day. The sewers could only discharge at the time of low water, and as the tide rose it closed the outlets, causing the sewage flowing from the higher grounds to accumulate in the low-lying portions of the sewers, where it remained stagnant until the tide was sufficiently low for the sewers to discharge. In times of heavy and long-continued rains, the closed sewers were unable to store the increased volume of sewage, which then rose through the house drains and flooded the basements of the houses, thus causing not only injury to health, but considerable damage to property. The construction of the Main Drainage Sewers at deeper levels has afforded better outfalls for the local sewers, of which advantage has extensively been taken by the vestries and district boards to re-construct their sewers, and thus the evils from which the inhabitants of the low-lying localities suffered have been removed. Further proof of the benefits derived from the main drainage is to be found in the increased and increasing purity of the river, of which the number of fish which continue to be found, even in those parts of the river which were formerly the most polluted, affords undoubted evidence.

Closely connected with the subject of the Main Drainage scheme is the question of the utilisation of the sewage of the metropolis. In this matter the Metropolitan Board has not made such progress as it has in its constructive operations. Our readers are doubtless aware that in the year 1865 the Board granted a concession of the sewage of the northern portion of the metropolis to the Metropolis Sewage and Essex Reclamation Company, upon the understanding that the company would construct culverts for the purpose of conveying the sewage from the outfalls of Barking Creek, for distribution on sands to be reclaimed from the sea at Maplin on the Essex coast. The company deposited with the Board the sum of £25,000 as a guarantee for the due execution of the works within four years from the passing of the Act; that is, the works were to be completed by June last. By an amending Act, however, which the company obtained in 1866, the time for the completion of the works was extended till July, 1870. The company entered into a contract for the construction of a culvert to convey the sewage to Maplin, in accordance with their agreement with the Board, and a portion of the culvert was constructed. The sum total of the matter, however, is that the company have not been able to continue the works, which is to be regretted.

Turning to the utilisation question upon the south side of the Thames we find that at the date of their last report, the Board had before them proposals from parties who were desirous of obtaining the concession of the southern sewage. The Board then stated that active steps in the matter had been delayed in consequence of the difficulty experienced in raising funds for public companies. Those proposals were the subject of a report of a committee to the Board on January 8 in the present year. The committee stated that many circumstances tended to prevent their recommending the acceptance of either of the proposals. Mainly, however, this result was attributed to the financial depression consequent on the crisis of 1866, which more or less affected adversely all commercial schemes, but particularly such as partook of a new or experimental character. The committee stated that they had several times adjourned the consideration of the tenders in the hope that the Board might be able to deal satisfactorily with them, but as that was not the case, and as the works of the company who had the concession of the sewage on the north side of the Thames had been for some time in abeyance, it appeared desirable to postpone for the present the consideration of the question of the southern sewage. We trust, however, that this postponement of the question will be only temporary, and that a revival of enterprise and the re-establishment of more favourable financial conditions will enable the subject to be more successfully dealt with at some future period.

We cannot conclude our present notice without referring to the ventilation of sewers in the metropolis. This question, which is one of great importance as affecting the health of the metropolis, is surrounded with many difficulties, and it appears that the Board have hitherto been unable to adopt any mode of dealing with it sufficiently sure and practicable to enable it to be applied generally throughout the metropolis. Two or three years ago various experiments were made by the direction of the Board, first, by the use of charcoal ventilating grates, second, by ventilation through chimney shafts and furnaces, third, by ventilation through pipes carried to the tops of buildings, and fourth, by dilution of the sewage with water. The subject is now under the consideration of a committee of the Board, and by their direction, the engineer has recently caused the whole of the sewers to be examined, in order to ascertain the number of untrapped gulleys and open air-shafts connected therewith, the number of cases in which these various methods of improving the ventilation have been adopted, the approximate cost thereof, and how far they may be deemed to have been successful.

The engineer has submitted his report to the committee, but they have not yet been able, having regard to the importance of the subject and the serious consideration it requires, to submit their views thereon to the Board. We trust, however, that they may shortly be enabled to do so, and that some effectual means of preventing the escape of foul gases from the sewers may soon be arrived at.

FOREST CONFLAGRATIONS.

THERE are three principal causes to which may be attributed the ignition of forests. They are wilful incendiarism, accidental incendiarism, and spontaneous combustion. Many persons are sceptical on the subject of the last-mentioned cause, but there is abundance of the most reliable evidence to prove that it has been productive of destruction not only to vegetable but also to animal life. In investigating the liability of forests to these several chances of conflagration, the first may be omitted, as it is scarcely possible to prevent an evil-disposed person setting

fire to a wood if he be so inclined. The other two causes may be guarded against, as they depend upon a variety of existing contingencies, which are well known and recognised as imparting an inflammable tendency to the standing timber. As may be anticipated, the nature of the trees, the character of the soil, and the geographical locality exercise considerable influence upon the chances of combustion. That the mineralogical constitution of the soil plays an important part in these instances becomes evident as soon as attention is directed towards forests, some of which spring from a calcareous and others from a granitic substratum. The oak, the pine, and the arbutus, which together are frequently met with growing upon the former description of geological formation, are thus comparatively secure from ignition. There is very little, if any, accumulation of brushwood, and moreover it is not of a very inflammable nature, so that even when a fire does occur it rarely commits any very serious or extensive devastation. The case is widely different when the character of the soil is granitic, and is in fact composed of the disintegrated particles of primitive rocks. This imparts an especial resinous property to the vegetable productions, and also largely increases the quantity of brushwood, particularly of the heather, which is the most dangerous specimen of the class. It is in this mass of dry wood and *debris* that lurk the seeds of future conflagrations, and which feed them until they acquire sufficient fierceness to seize upon the larger trees, and extend their ravages sometimes over a whole district. During the hot season this inflammable mass becomes desiccated to so extreme a degree as to be ignited by the merest spark, and the rapidity with which the flames spread seldom leaves much chance of extinguishing them. As a rule, the fire is extinguished by consuming itself. It dies out.

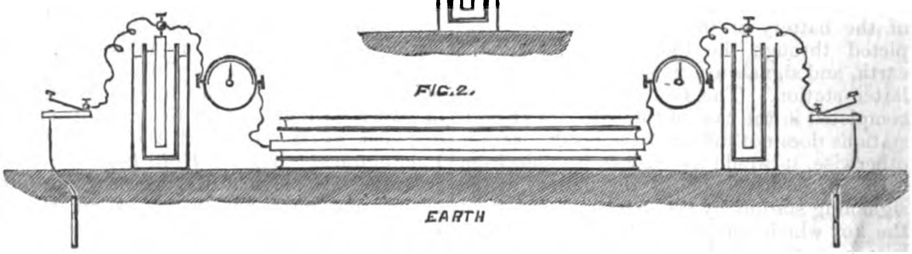
A peculiar feature in these conflagrations, where pine trees are among the victims, is the burning of their cones, which materially adds to the violence and extension of the catastrophe. Under the influence of the intense heat, the strobeels of these cones, still green and filled with sap, burst open with considerable violence and propulsive effect, sending their ignited contents to a distance of several hundred yards, there to act as the agents of fresh fires. From this cause it has frequently happened that all attempts to cut off and separate the burning area from the rest of the forest have been frustrated, and those engaged in the task have beheld with dismay and despair flames springing up in different parts of the forest without any apparent or assignable reason. Bearing in mind what an accumulated mass of inflammable materials exists in a large forest, there is need of no comment to indicate that stringent precautions should be taken to diminish to a minimum the causes that might conduce to a conflagration. Among these are the careless use of the pipe or cigar, the imprudence of hunters, or the negligence of charcoal burners. As there are now no actual forests in England, our remarks apply principally to those of foreign countries. A very frequent cause of the firing of forests is due to a habit, or rather custom, of the agricultural population to procure a manure for the ground. For this purpose they arrange here and there on the field or plot which is to receive the next sowing, a number of small bonfires composed of dead boughs, dried leaves, and other timber *debris*, and covered by grass sods, with the grass turned inside. By the incineration of these vegetable components a very excellent manure is procured. However desirable in an agricultural point of view these operations may be, the danger of conducting them in close proximity to a large forest ready to ignite at the shortest notice is so imminent that it is a wonder the authorities permit the practice to be continued.

The attention of our neighbours on the opposite side of the Channel has been recently very forcibly directed towards this subject by a conflagration in Corsica, which lasted over eight days, and destroyed an enormous quantity of valuable timber, together with a large amount of miscellaneous property. Although a fire of this nature is by no means an uncommon event in the Napoleonic isle, yet when it arrives at such a magnitude it unquestionably demands an inquiry. Accordingly, the officer of the Crown, who in our country would answer to the Commissioner of the Woods and Forests, was directed to institute an inquiry into the cause of the disaster, with especial view to the prevention of so lamentable an occurrence hereafter. One of the precautionary methods which that gentleman recommends will at first sight appear rather startling. He proposes to set fire to the forest, although not exactly to the same extent that prevails when it takes place under other circumstances. But it is very properly pointed out in the report that, by the lighting and maintenance of small fires under careful surveillance, the brushwood could be easily destroyed, and thus the principal danger removed. It is also strongly insisted upon that the larger trees should be more frequently and more thoroughly thinned, and that their dead branches should be removed instead of being permitted to fall from the tree and so serve as convenient fuel for the next fire. As an additional precaution, the forests ought to be more intersected by roads than they are at present, so that they might be better commanded in the hour of danger, and more accessible to the means employed for their rescue and preservation. Other advantages would accrue to the proprietors of forest property by the multiplication of the means of intercommunication and transport. Not the least of these would be the rise in value of the property itself, which in every country is directly proportional to these pioneers of civilisation. The comparative security or non-security of a forest from fire altogether fixes its value. The forests of Corsica that are regarded as exempt from conflagration are valued at about £14 the acre, and those that are considered inflammable at just half that sum. At the approaching legislative session it is intended to lay before La Chambre a bill embodying the measures best calculated to diminish, if not prevent, the occurrence in future of disasters so calamitous.

FITZGERALD'S SYSTEM OF ELECTROLYTIC INSULATION.

FIG. 1.

FIG. 2.



ELECTROLYTIC INSULATION.

We have recently met with some very interesting and striking improvements in telegraphy which involve an entirely new system of constructing lines of electric telegraph, or of insulating a signalling current, and which have been patented by Mr. D. G. Fitzgerald. In this system, which is equally applicable to aerial, underground, and submarine lines, no insulating material properly speaking—that is to say, no dielectric—is employed; the lateral passage of the signalling current being prevented by a combination of metallic and electrolytic conductors so arranged as to generate an electromotive force which opposes the escape to earth of the current. The principle upon which is based this somewhat startling innovation in telegraphy will be seen on reference to the accompanying diagrams. Fig. 1 represents a battery of two cells constructed according to Mr. Fitzgerald's invention. The outer vessel is of lead or copper, the inner vessel of the same metal covered externally with zinc, and the central element is a cylinder of zinc. The two cells may thus be said to be included in one. Supposing the tensions of the poles of a single couple constructed of similar elements, and excited with dilute acid or a saline solution, to be respectively + 5 and − 5 when the couple is insulated, the tension of the zinc pole of the battery here represented will be − 20 when the outer vessel is in contact with earth. The same will be the case if hemp, slightly impregnated with a good electrolytic conductor, be interposed between the metallic elements in lieu of the ordinary exciting fluid.

It is to be observed that the zinc pole of this arrangement constantly retains its minus charge, although it is directly connected with earth by a series of metallic and electrolytic conductors. In the case of ten cells similarly arranged the free negative pole would constantly retain a charge at the tension of − 100; and under no circumstances could electricity at this or a lower minus tension escape to earth by traversing the conductors intervening between earth and the central zinc element. It is evident therefore that a series of metallic and electrolytic conductors, disposed as shown in the diagram, is capable of effecting the insulation or preventing the passage to earth of a negative charge, or of a current from the negative pole of a battery. In order to distinguish this mode of insulation from that which is effected by non-conductors of electricity, Mr. Fitzgerald terms the former "electrolytic insulation" and the latter "dielectric insulation."

The rationale of the construction and working of an electrolytically-insulated telegraph line will be explained by fig. 2, in which an underground cable, constituting an elongated battery analogous to that which has been above described, is supposed to extend between two signalling stations. The central conductor, both in the cable and the station batteries, will here acquire a negative tension, precisely as in the case of the battery shown in fig. 1, since the arrangement may be regarded as simply a longitudinal extension of this battery. Until the signalling key at either station be depressed, no current can traverse the line and influence the receiving instruments; the conductive circuit being otherwise incomplete, or the negative

pole of the longitudinally extended battery insulated from earth. To trace the effect of depressing the key at the right side of the figure, for instance, it is necessary only to consider that this key is in connection on the one hand with the line conductor, that is to say, with the negative pole of the battery on the left side of the figure, and on the other hand with earth, that is to say, with the positive pole of this battery, which is in contact with earth. By working the key at one station, therefore, the circuit of the battery at the other station is completed through the line, instruments, and earth, and signals are thus transmitted to the latter station. The fact that the circuit is completed in the case of the batteries at both stations does not influence the result; were it otherwise, it would be easy to insulate from earth the positive pole of the battery at the signalling station by the same movement of the key which completes the circuit of the battery at the receiving station.

The electrolytic conductor employed in the construction of the cable is hemp or other vegetable fibre which has been saturated with a saline solution and subsequently dried, though it still retains sufficient moisture to allow of its generating, by contact with dissimilar metallic surfaces, the electromotive force which opposes and prevents the lateral passage of the signalling current. In overland lines, the electrolytic insulation of the conductor, instead of being continuous, is effected only at the points of support along the line, the dielectric air being, as in the ordinary system of overland construction, the principal insulating medium.

The foregoing remarks suffice to explain the main points of the theory of a system of insulation which may very probably ere long be adopted in telegraph construction. We shall await the conclusion of the experiments now being carried out under distinguished scientific; supervision to determine the most advantageous form of electrolytically insulated cable before entering into further and more practical details of the invention.

ATMOSPHERIC INFLUENCE ON THE TIDES.

A GREAT deal of anxiety and curiosity was excited in the public mind in reference to the spring tides of October 6th. This resulted from a widely circulated prediction of inundations to low-lying districts. But the event completely falsified the dismal prophecy. The tides were as nearly as could be in accordance with the scientific information furnished by the Admiralty Tide Tables. It has been since argued that the tides were experienced as a consequence of the state of the weather, and that had the weather been different the inundations might have occurred. Although this reasoning seems to have been most appreciated after the event, there is no doubt that there is truth in it. In calling attention to the matter, we have in view a suggestion which, if carried out, would relieve the public of any necessity of alarming itself in a similar manner without an existing cause.

The astronomical data upon which tide predictions are calculated are well known, and, so far as astronomical causes are concerned, the height and times of tides can be accurately computed beforehand. But the tides are affected by meteorological causes, as the presence of storms, prevailing winds, and atmospheric pressure; and these are variable causes which cannot be employed as data in tide calculations, and, indeed, are barely recognisable within one or two days before the event. The tide tables give the tide elevations for what may be considered the ordinary state of the atmosphere. Conditions of great or of low atmospheric pressure, or of storms or strong winds, can only be taken into account a few days or perhaps a few hours previous to the time when the tide is due.

Meteorologists have shown that wherever over the sea an area of low atmospheric pressure exists there the level of the water rises proportionally to the deficiency from the average; the contrary occurring with a prevalence of high pressure. Theory would give about thirteen inches rise of tide for one inch fall of mercury in the barometer; and this has been verified by tide-gauges. In this manner the cyclonists account for the cyclone wave, which is a kind of heaping up of the water under the centre of the meteor, and being carried forward by it is virtually a wave. They also account for the formation of storm-currents, or drifts of the sea occasioned by the force of the storm-wind. Piddington's "Sailor's Horn-book" quotes from the "Geological Report on Cornwall, Devon, and West Somerset," by Sir Henry De la Beche, the following very interesting account of the influence of winds on the tides:—

Mr. Walker* has observed with respect to the influence of the pressure of the atmosphere upon the tidal waters on the shores of Cornwall and Devon, that a fall of 1in. of the mercury in the barometer corresponds to a rise of 16in. in the level of the sea, more than would otherwise happen at the same time under the other general conditions, a rise in the barometer of 1in. marking a corresponding fall in the sea level of 16in. This he has found to be the usual rate of such alterations in level, but very sudden changes in the pressure of the atmosphere are accompanied by elevations and depressions equal to 20in. of sea water for 1in. of mercury in the barometer. Regarding the whole pressure of the atmosphere over the globe as a constant quantity, all local changes in its weight merely transfer a part of the whole pressure from one place to another, and hence he concludes that the subjacent water only flows into or is displaced from those areas where, for the time, the atmospheric pressure is either less or greater than its mean state, in accordance with the laws which would govern the indication of two fluids situated in the manner of the atmosphere and sea. We might account for the difference observed by Mr. Walker in the amount of depression or elevation of sea level produced by sudden changes in atmospheric pressure by considering that a sudden impulse given to the particles of water, either by suddenly increased or diminished weight in the atmosphere, would cause a perpendicular rise or fall in the manner of a wave beyond the height or depth strictly due to the mere change of weight itself.†

As regards the influence of the winds on the mean level upon the south coast of Cornwall and Devon, Mr. Walker observes that east and west winds scarcely affect it, but that southerly winds raise the sea above it from 1in. to 10in., and off shore winds depress the water beneath it as much according to their force. On the morning of November 29, 1836, when the velocity of the wind was estimated at about 100ft. per second, the sea at Plymouth was raised 3ft. 6½in. above the mean level, the greatest height above the equilibrium level he has seen. The hurricane began at S.W., and the barometer was very low, therefore this great increase in height is due both to the wind and diminished atmospheric pressure. A gale of wind from the southward, a low barometer, and a high spring tide concurring, cause damage and inundations on the southern coast of Cornwall and Devon. From the form of the British Channel and the absence of a free passage for the waters, such as exists at the Straits of Dover, in the English Channel, westerly winds force up and sustain a great body of water, thereby raising the sea above the mean level several feet. It appears from an account of the great storm of November 26, 1703, that the tide flowed over the top of Chepstow bridge, inundating all the low lands on both sides of the Severn, washing away farmyards, drowning cattle, &c., and it is worthy of remark that the barometer is recorded to have then fallen lower than had ever been previously noticed.

This quotation leads to the suggestion which we have to make, namely, that the indications of tide-gauges at critical times of the tides should be carefully watched and reported by telegraph to the Meteorological Office; and that the office should be charged with the duty of interpreting these indications, in connection with its duty of watching the weather, and should make known its opinions or conclusions to the public as speedily as possible by the same means as it adopts to disseminate a knowledge of the weather. The subject is the more worthy of the consideration of the Meteorological Committee because their staff alone has the means of keeping a daily watch upon the weather. Neither the Admiralty nor the Board of Trade could attend to this matter. It would appear that every facility will shortly be afforded for undertaking this duty. By a Bill to consolidate and amend the Acts relating to Merchant Shipping and Navigation, brought forward in the House of Commons on the 9th August by Mr. Shaw Lefevre, it is proposed to enact that "The harbour authority shall, on being required to do so by the Board of Trade, provide, and until relieved from this duty by the Board of Trade shall always hereafter maintain in good order, at such place and in such manner as the Board of Trade direct or approve, an efficient self-registering tide-gauge with a barometer; and shall cause accounts of the workings thereof to be kept and to be sent to the Board of Trade, in such manner and at such time as the Board of Trade direct or approve." Penalties are to be enforced for not providing or not attending to these instruments.

* Assistant Master Attendant H.M. Dockyard, Devonport.

† A circumstance connected with this subject of considerable practical value has been noticed by Mr. Walker during his long-continued observations. He has found that changes in the height of the water's surface, resulting from changes in the pressure of the atmosphere, are often noticed on a good tide-gauge before the barometer gives notice of any change. The practical value of the observation is, be the cause of the phenomenon what it may, that if tide-gauges at important dockyards show that a sudden change of sea level has taken place, indicative of suddenly decreased atmospheric weight, before the barometer has given notice of the same change, all that time which elapsed between the notices given by the tide-gauge and barometer is so much gained, and those engaged with shipping know the value of even a few minutes before the burst of an approaching hurricane.

TELEGRAPHIC NOTES.

IN our issue for the 8th inst., we gave particulars of the proposed Falmouth, Gibraltar, and Malta submarine cable, which will be 2,462 knots in length. We are glad to find from the directors' report—which has just been issued in anticipation of the meeting to be held on the 2nd proximo—that preliminary matters are progressing satisfactorily. The shares have been allotted, and the allotment money has been almost entirely paid. The order for the cable has been given to the Telegraph Construction and Maintenance Company, and the sum of £30,000 has been paid to them, in accordance with the contract. They have commenced the manufacture of the cable, and there is every reason to believe that it will be completed within the contract time. The directors have been in communication with the Postmaster-General with reference to the transmission of their messages between London and Falmouth and have obtained the promise of special wires for their traffic, together with other accommodation at the Metropolitan terminus, and the enjoyment of equal privileges with those accorded to any other telegraph company. This company has joined with the Anglo-Mediterranean Company in purchasing from the Telegraph Construction Company the steamer "Hawk," with her machinery and stores, to be used as a repairing ship, which will be very advantageous to the interests of the company. The directors have appointed Sir James Anderson the managing director of this company, an office which he also holds in the Anglo-Mediterranean and British-Indian Companies, thus practically bringing the three companies under one management. They have also appointed as their permanent secretary Mr. E. B. Bright, the secretary of the British and Irish Magnetic Telegraph Company, which is now about to be absorbed by the Government. Mr. Bright's great experience in connection with telegraphy will render his services peculiarly valuable to this undertaking. The manufacture of the cable for the British-Indian Company is rapidly approaching completion. True to her time, the "Great Eastern" steamship left Sheerness for Bombay on the 23d inst. with upwards of 2,200 miles of cable on board, and the remainder will follow very shortly in two other steamships. The laying is expected to be finished in March next. The Falmouth cable is expected to be laid within a few weeks afterwards, so that the whole line of submarine communication between England and

India will be completed sooner than had been originally announced.

A few remarks which recently appeared over the initials "H. G." in the Society of Arts "Journal" will serve to illustrate the manner in which government control over the telegraphs in France is exercised for the convenience and benefit of the public. After the 1st November next, the charge for a message from any one port of France to another will be reduced from 2fr. to 1fr., or to something under one shilling. The reduction of the uniform rate of 1fr. was enacted by the Chamber of Deputies in July, 1868; but more than a year has been required to make preparations for the increased correspondence which is expected to ensue on the increase of facilities and diminution of charge. Besides the construction of numerous branch lines, the Morse instrument has been replaced by the Hughes' printing apparatus at all the important stations. The use of Hughes' apparatus doubles the rapidity of communication, in other words, will enable twice as many messages to be forwarded in the same time. The number of offices has been greatly increased; it now amounts to 2,701, of which 1,071 are government offices, the remaining 1,000 being at railway stations, whence messages are forwarded according to an arrangement made with the government. No difficulty is experienced in obtaining the required number of signallers. At the last examination 230 were admitted. At present the French telegraph extends over 25,000 miles of line, and the number of messages annually amounts to 3,500,000. In the year 1865, according to Mr. Bright, the United Kingdom possessed 16,000 miles of line, over which 4,650,000 messages were forwarded. The principal improvements effected by the French government, within the last few years, may be briefly enumerated:—1. Reduction of the charge to the uniform rate of 1fr. 2. The introduction of Hughes' printing apparatus, improved by the late M. Froment, who rendered the instrument workable, which it was not previously. 3. A new and very efficient organisation of the pneumatic system, by which messages are forwarded collectively from the centres of various districts to the centres of other districts, instead of transmitting the messages successively, or one after the other, as was formerly the case. 4. The introduction of Meyer's instrument, which forwards a *fac-simile* of the message received, and thus renders any error on the part of the telegraph impossible.

Mr. W. J. Conlan, the secretary of the Pacific Steam Navigation Company, writes to the "Times" the following letter, which beautifully illustrates the manner in which the telegraph system between this country and Portugal is conducted:—Sir,—Allow me to call attention to the extraordinary manner in which telegrams from Lisbon reach this country. This company's outward-bound mail steamship "Cordillera" arrived at that port at noon on the 19th inst., and left on the evening of the same day. The homeward-bound mail steamship "Araucania" arrived on the evening of the 19th, and left again on the evening of the 20th; and the telegrams in connection with these movements came to hand as under:—No. 1, private telegram, 21st, 9 a.m., despatched from Lisbon 18th, 8 p.m.; No. 2, departure of "Araucania," 21st, 11 a.m., despatched from Lisbon 20th, 7.30 p.m.; No. 3, departure of "Cordillera," 21st, 5 p.m., despatched from Lisbon 19th, 6 p.m.; No. 4, arrival of "Cordillera," 22d, 12.30 a.m., despatched from Lisbon 19th, 3.53 p.m.; No. 5, supplementary news by "Araucania," 22d, 1 a.m., despatched from Lisbon 20th, 2 p.m.; No. 6, arrival of "Araucania," 22d, 9 a.m., despatched from Lisbon 20th, 10 a.m. We have been in the habit of receiving telegrams from Lisbon for several years past, and the irregularities all along have been considerable, but the extraordinary confusion in the arrival of the above messages is without a parallel in our experience. I need scarcely add that the telegrams were all more or less unintelligible. No 5, which consisted of 83 words, afforded scarcely a chance of interpretation, and we were obliged, in consequence, to withhold its contents from publication. "Congress has gefealted cuantie," and "ronesings generally brisck accept in niahete hade" are fair samples of the "news" it contained.

The Post-office authorities are actively proceeding with the arrangements necessitated by the impending transfer of the telegraphs to that department. At Lincoln the new telegraph office is expected to be located in Guildhall-street, as near the post-office as possible, the wires being continued thereto from the post, which is about midway between the High-street and The Holmes. Alterations have been commenced at the Leicester post-office for the accommodation of the new branch of postal business; the contract has been let to Messrs. Neale and Son, and Mr. G. Reavell will act as clerk of the works. In Suffolk, Essex, &c., the extensions involved by the new system are being carried out under the superintendence of Mr. Sach. Among the towns to which the telegraph will be extended are Botesdale, Bungay, Brightlingsea, Dedham, Eye, Framlingham, Haughley, Haverhill, Hadleigh, Halesworth, Harleston, Ixworth, Long Melford, Leiston, Needham Market, Orford, Scole, Stowmarket, Wivenhoe, Walton-on-the-Naze, &c.

The number of messages through the French Atlantic Telegraph during the week ending the 23d of October was 692, the cable charge thereon being £1,636, showing a decrease of £252 from the preceding week.

NOTES ON RECENT DISCOVERIES IN SCIENCE AND THEIR PRACTICAL APPLICATIONS.

ARTIFICIAL PORPHYRY FROM IRON SLAGS—NEW WAY OF MAKING LEAD PIPES WITH A TIN LINING—NEW SEWING COTTON—THE ORNAMENTATION OF PLASTER CASTINGS—A NEW RED DYE.

At the ironworks of Aulnoye, in Belgium, the slag is utilised by casting it into slabs for paving, garden rollers, and other things. For the former purpose, moulds are excavated in the ground around the furnaces of sufficient extent to receive all the slag running from them, and trenches are cut to carry the liquid slag. The only precaution to be taken, we are told, is to cause the slag to run under the vitreous layer, which solidifies at the beginning of the running, and to keep the moulds warm, so that the slabs may not solidify too rapidly. For this purpose it is often necessary to cover up the trenches and moulds with cinders and small coal. The cooling should, indeed, be made to occupy several days; and, in that case, there will be found under the vitreous crust a compact homogeneous slab, in appearance very much resembling natural porphyry. The masses are often divided by fissures, but the pieces can be dressed and trimmed into blocks for paving. To obtain sound rollers, it is necessary to take especial care in the cooling and solidifying It is hardly necessary to add that the slags employed for these purposes must be solid and lasting, and not at all brittle.

A new way of manufacturing lead pipes with a lining of tin has been devised by M. J. Grand, jun. The first step is the formation of a muff coated with tin on the inside. This is made in a horizontal mould, which is made to revolve with great rapidity, and is provided with a hollow axle through which the metals are introduced. The metals are fused in a crucible furnished with a stopcock or a clack valve opening into the hollow axle of the mould. One crucible will suffice, the lead being placed at the bottom and the tin on the top, the two being separated by an iron grating; or the tin may be melted in a separate crucible provided with a valve and placed above that in which the lead is melted. The object is, of course, to run the lead into the mould first, and to allow the tin to follow while the former metal is still liquid. A rapid movement of rotation keeps the two metals from mixing, while a perfect junction is formed as they solidify. When sufficiently cooled, the muff is transferred to the press, and the pipes are squeezed out in the usual way. Tin lined pipes ought to command an extensive use for carrying soft waters and beer, and, no doubt, would be employed if they could be produced at a small advance on the price of lead piping. The plan of manufacture described here deserves attention, although it seems open to doubt whether the lining surface of tin would be perfectly continuous in the pipes. No doubt the adhesion of the two metals would be perfect.

M. Masson has introduced a sewing cotton of increased strength made by spinning together linen and cotton fibres. The proportion of the two fibres may be varied according to the work the thread is to be used for.

There has been a difficulty in getting a good ground for painting upon plaster ornaments and cements which seems to us to have been entirely removed by M. Rimbaud, a Parisian sculptor. This gentleman first applies a coating of solution of albumen in acetic acid. The proportions he employs are one part of albumen and five parts of acetic acid. He does not mention the strength of the acetic acid, but it need not be strong. This solution completely stops the pores of a plaster or of a spongy stone, and forms a firmly adherent skin to which any paint or varnish can be applied. The inventor suggests various modes of ornamentation, marbling, graining, &c., which will readily occur to a painter and decorator when he is furnished with a ground he can easily work upon.

By the action of oxidising agents, M. Girard has succeeded in converting pyrogallic acid into a red dye very like alizarine. It is, like pyrogallic acid, a volatile substance, and, by the further action of nitric acid, it is converted into picric acid. The cost of pyrogallic acid in comparison with that of madder will leave little chance of any commercial application of M. Girard's discovery.

ENGLISH AND CONTINENTAL INTER-COMMUNICATION.

By Mr. Perry F. Nursey.

(*Concluded from page 297.*)

BATEMAN.

The uncertainty of the strata in the bed of the Channel and the risks of tunnelling under the sea have led Mr. J. F. Bateman, in conjunction with M. Julian J. Rèvy, an Austrian engineer, to propose a cast-iron tube for carrying a railway across the Channel. The distance to be crossed, and the cost to be incurred, undoubtedly require that the mode to be adopted shall be absolutely free from serious doubt and risk, and shall be as evidently capable of accomplishment as the most ordinary mechanical operation. Some degree of uncertainty must exist in every contrivance and speculation; but, unless a scheme can be proposed which will be free from all doubt and objection so far as human knowledge and foresight can extend, it will hardly deserve, and will probably not receive, the support of the public. The various proposals for constructing submarine tubes have been carefully studied by Mr. Bateman and M. Rèvy, who have come to the conclusion that none of them are free from serious objections, both on the score of difficulty of construction and the dangers which would attend the operations as proposed. Their object, therefore, has been to devise a scheme by which all difficulties of operating in water should be avoided.

They propose to lay a tube of cast iron on the bottom of the sea, between coast and coast, to be commenced on one side of the Channel, and to be built up within the inside of a horizontal cylinder or chamber, which shall be constantly pushed forward as the building of the tube proceeds. The chamber within which the tube is to be constructed will be about 80ft. in length, 18ft. internal diameter, and composed of cast-iron rings 8in. thick, securely bolted together. The interior of the bell will be bored out to a true cylindrical surface like the inside of a steam cylinder. The tube to be constructed within it will consist of cast-iron plates in segments 4in. in thickness, connected by flanges, bolted together inside the tube, leaving a clear diameter of 13ft. when finished. Surrounding this tube, and forming part of it, will be constructed annular discs or diaphragms, the outside circumference of which will accurately fit the interior of the bell. These diaphragms will be furnished with arrangements for making perfectly water-tight joints, for the purpose of excluding sea water and securing a dry chamber, within which the various operations for building up the tube, and for pressing forward the bell as each ring of the tube is added, will be performed. There will always be three and generally four of these water joints contained within the bell. A clear space between the end of the tube and the end or projecting part of the bell of 36ft. will be left as a chamber for the various operations. Within this chamber powerful hydraulic presses, using the built and completed portion of the tube as a fulcrum, will, as each ring is completed, push forward the bell to a sufficient distance to admit the addition of another ring to the tube. The bell will slide over the water-tight joints described, one of which will be left behind as the bell is projected forward, leaving three always in operation against the sea.

The weight of the bell and of the machinery within it will be a little in excess of the weight of water displaced, and, therefore, the only resistance to be overcome by the hydraulic presses when

pushing forward the bell is the friction due to the slight difference in weight and the head or column of water pressing upon the sectional area of the bell against its forward motion. In like manner, the specific gravity of the tube will be a little in excess of the weight of water which it displaces; and in order to obtain a firm footing on the bottom of the sea, the tube will be weighted by a lining of brick in cement, and for further protection will be tied to the ground by screw piles, which will pass through stuffing boxes in the bottom of the tube. These piles will, during the construction of the tube within the bell chamber, be introduced in the annular space between the outside of the tube and the inside of the bell, and will be screwed into the ground as they are left behind by the progression of the bell. The hydraulic presses and the other hydraulic machinery, which will be employed for lifting and fixing the various segments of the tube, will be supplied with the power required for working them from accumulators on shore, on Sir William Armstrong's system, and the supply of fresh air required for the sustenance of the workmen employed within the bell and within the tube will be insured also by steam power on shore. As the tube is completed, the rails will be laid within it for the trains or waggons to be employed in bringing up segments of the rings as they may be required for the construction of the tube, and for taking back the waste water from the hydraulic presses, or any water from leakage during the construction.

The tube will be formed of rings of 10ft. in length, each ring consisting of six segments, all precisely alike, turned and faced at the flanges or joints, and fitted together on shore previous to being taken into the bell, so that on their arrival the segments may, with certainty and precision, be attached to each other. Every detail of construction has been designed, and, so far as the authors of this project can see, no contingency has been left unprovided for. The possibility of injury by anchors or wrecks, or submarine currents, has also been investigated. The tube when laid will be secure from all dangers arising from such causes.

The building of the tube will be commenced on dry land above the level of the sea, and will be gradually submerged as the tube lengthens. The operations on dry land will be attended with more difficulty than those under water, but all these circumstances have been carefully considered and provided for. The rings forming the tube will be made by special machinery, to be expressly constructed for facilitating the work and economising the cost. This machinery is all designed and specified. The first half mile will test the feasibility of construction, for that will have to be built both above and under water. When once fairly under water, the progress should be rapid, and it is estimated that the whole undertaking may be easily completed in five years from the commencement.

The precise line to be taken betwixt the English and French coasts can hardly be determined without a more minute survey of the bottom of the Channel than at present exists. It will probably be between a point in close proximity to Dover on the English coast, and a point in close proximity to Cape Grisnez on the French coast. From an examination of the Admiralty charts, and of such information as at present exists, the sea bed on this line appears to be the most uniform and level, and, while free from hard rocks and broken ground, to consist of coarse sand, gravel, and clay. The average depth of water is about 110ft., the maximum about 200ft. On the line suggested, the water increases in depth on both sides of the Channel more rapidly than elsewhere, although in no instance will the gradient be more than about 1 in 100. The tube, when completed, will occupy about 16ft. in depth above the present bottom of the sea. Up to the point on each shore at which the depth of water above the top of the tube would reach (say) 30ft. at low water, an open pier or other protection would have to be constructed, for the purpose of pointing out its position, and of preventing vessels striking against the tube. These piers may be rendered subservient to harbour improvements. The tube at each end would gradually emerge from the water, and on arriving above the level of the sea would be connected with the existing railway systems, so that the same carriage may travel all the way from London to Paris.

The distance across the Channel on the line chosen is about 22 miles. The tube as proposed is large enough for the passage of carriages of the present ordinary construction, and to avoid the objections to the use of locomotives in a tube of so great a length, and the nuisance which would be thereby created, and taking advantage of the perfect circular form which the mechanical operation of turning, facing, &c., will ensure, it is proposed to work the traffic by pneumatic pressure. The air will be exhausted on one side of the train and forced in on the other, and so the required difference of pressure will be given for carrying the train through at any determined speed. Powerful steam engines, with the necessary apparatus for exhausting and forcing the air into the tube, will be erected on shore at each end; and supposing one tube only to exist, the traffic will be worked alternately in each direction. This system of working the traffic will secure a constant supply of the purest air, which will accompany every train.

The estimated cost of the whole undertaking, including the stations and approaches at each end, the engine power and machinery, the interest of outlay during construction, and engineering superintendence, with a large margin for contingencies, is £8,000,000.

Grantham.

Mr. John Grantham's proposition for improving the communication between England and France is to turn the present system to account, and to make an efficient means of transit whilst the more elaborate schemes are being perfected and rendered practical. Mr. Grantham proposes steamships 400ft. long, 45ft. beam, and 600 nominal horse power, to be built of steel, and to draw 6ft. 6in. water, and to steer from either end, to avoid the necessity of turning. The lower part of the ship is to be cellular, so as to avoid the danger of sinking if injured by a collision, and to add to her strength. This cellular portion is 6ft. in depth; over it would be the main saloons, these to be 10ft. in height, and provided with ample accommodation for reclining in bad weather; good refreshment tables also would be provided, with light and air to avoid that gloom and closeness so painful to landsmen when on board ship. Between the paddle boxes would be a promenade deck, 100ft. long, on the extremities of which would be the houses from which the vessel would be steered. To strengthen her amidships, with the least amount of weight, there would be provided four open longitudinal girders, about 250ft. long, so arranged as to cause very little obstruction on the ship, and longitudinal bulkheads, about 90ft. long, would run through the engine compartment. In addition to these precautions, the plates of the sides would be extended up, and form the inner side of the paddle-box, drawn off towards the ends at the same angle as the trussed girders.

In order to facilitate the transfer of passengers and luggage from the piers to the ship, wide and ample means are provided, at three different elevations, to receive the stages from the shore. The lowest of these is on the level of the main deck; the next is on the level of the promenade deck, and the upper one is on the paddle-boxes or on the captain's platform; so that, whatever should be the state of the tide, the stages may rest on the top of the piers, and be nearly level. On the piers are to be erected sheds, under which the trains are to run, as in ordinary railway stations, to be well enclosed and lighted, so that but little delay or discomfort would arise. The staircases leading from the promenade platform to the deck should be easy, wide, well-lighted, and sheltered. The great bulk of the luggage would be stowed in trucks, the bodies of which would be hoisted by hydraulic cranes on to the deck, and again lifted off on the other side, and placed on wheels provided for them. In all this there is no novelty introduced; all that is proposed may be seen in operation in other places. The only question that can be raised is as to the facility of working a vessel, such as is here described, in and out of the harbours. For experience in this, Mr. Grantham refers to the American steamers, which are managed with wonderful precision. These vessels have in some instances exceeded 400ft. in length. Those on the rivers draw 5ft. and 6ft. of water, and those which put to sea vary from 7ft. to 10ft.; but all are of immense height out of water, the wheel-houses of some being upwards of 40ft. above the water-line. Mr. Grantham's vessel, though drawing only 6ft. 6in., will not exceed 15ft. above the water-lines at the ends. Long vessels steer much more steadily in heavy weather than short ones, and will, therefore, enter such harbours as Calais or Boulogne with more safety than the present vessels, and, when fairly entered, there is time to bring them to a standstill before reaching their berths.

Mr. Grantham gives the following reasons for not adopting a vessel in which the trains should be carried bodily across:—First, there is the necessity of placing the vessel in a position of perfect stillness before taking the trains on or off the ship. This involves new harbours on each side, with dock gates and breakwaters to protect them. Second, the large ships necessary to carry the trains will take a long time in bad weather before they can be placed in position and the gates closed. Third, very few persons would remain in the carriages when being put on board, and, in the event of sea-sickness, they could not be allowed to remain, so that the passengers must have time to leave the carriages and walk on board. Lastly, the large outlay in forming the harbours, appliances for shipping the trains, and the extra cost of the ships, together with the heavy cost of working them.

Boutet.

The great bridge scheme for connecting the two shores which is at the present time attracting a large amount of attention both in England and France—especially in the latter country—is the project of M. Charles Boutet. This gentleman, who is a French engineer, has been engaged during the past ten years in maturing his plans and constructing models in order to satisfy himself of the correctness of the principles he has enunciated. M. Boutet selects a point on the Dover Hills near the Shakspeare Cliff for the commencement of his International Bridge, which is to touch the coast of France at Blanc Nez, a short distance from Calais, at which place the cliffs are about the same height as those on the English coast. These cliffs, at either extremity rising nearly 400ft. above the level of the sea, serve as abutments for the proposed viaduct. To protect them against the destructive action of rain, winds, and frost, they will be faced with a solid construction of dressed stone. The project depends in effect on two remarkable innovations in the construction and establishment of the piers—of which there will be twenty-nine—and girders. In addition to the considerable height to which the former rise above the water (120yds.), the bases of the piers are sunk to the bottom at a depth varying from 28yds. to 52yds. The centre pier will be half as large again as the others. All the pieces composing the work are of cast iron.

As such ponderous piers could not be erected by the ordinary means, M. Boutet proposes to construct on the shore their lower parts or bases to a height sufficient to rise 10yds. above high water, and as soon as the iron skeleton is put together and bolted, a number of large sheet-iron buoys are distributed about the surface of the base. At low water the metallic framework thus prepared is made to slide upon the shore to low water mark. The tide in rising raises this raft or base of iron lightened by the buoys, and floats it. A tug steamer then removes it to its place, previously indicated by one of a line of buoys attached to an iron cable stretched across the Straits at a depth of 18yds. By raising one of the buoys attached to the raft it is made to descend very slowly, the top being just above the level of the sea when the base touches the bottom. It is foreseen that it may become necessary to rectify its position, and a strong metal screw is therefore placed in the interior of each pier, extending from base to summit, to which is attached a large buoy which can thus be moved from the top to the bottom or *vice versa*. The buoy disturbing the equilibrium renders the specific weight of the pile heavier or lighter than the displaced water, and the whole structure when floated to its place can be sunk without the least shock. It is manœuvred like a ship, and its position is verified by a special glass, invented by M. Boutet, to be placed on the cliffs. The base of the pier is provided with large screws or spiral feet, which on being turned bind it firmly to the solid bed of the sea, and serve to establish the level if necessary. Such is the method of moving and fixing the enormous bases of the piers, the component parts of which it would otherwise be extremely difficult to unite under water. The construction of the upper portion of the pier above the sea is effected piece by piece. Thus are avoided all the preliminary works under water, which constitute the greatest difficulty in the way of a bridge across the Channel.

Next with regard to the superstructure, M. Boutet has hit upon a plan whereby the difficulties of transport, &c., are overcome. He constructs rigid beams endowed with great powers of resistance of a weight relatively very small, and capable of being placed in position piece by piece, by the aid of a system of scaffolding constructed as follows:—Between the abutment on the shore

and the first large pier, 3 temporary piers are placed at equal distances. This done, there are stretched in parallel lines a number of wire cables 2 metres (*i.e.*, 2yds. 6in.) apart. They are connected and bound together by ties made of smaller cables, which interlace the large ones and hold each in its place. The whole forms a truss of 63yds wide. The truss thus made is covered by a wooden flooring, a guard is fixed on each side, and there is at once obtained a service bridge upon which scaffolding is erected to support the roadway of the bridge during its construction, the scaffolding being always at a sufficient height above the sea to allow the largest vessels to pass under it. Upon such scaffolding are supported the wire cables forming the roadway of the bridge —each of which is strained as nearly to a right line as possible, after which smaller cables are interwoven, bracing together the main cables and holding them firmly in their places. Each cable is composed of eight iron wires parallel to each other and bound together at intervals with strong wire collars. The straining of the large cables is to be managed by means of weights, which are removed after the proper degree of tension has been attained and the cables fastened down to the tops of the piers. For example, we will assume the cable to be fixed at the abutment and laid loosely over the other piers, the weight would then be applied to the length of cable between the first and second piers. This would bring the length between the abutment and the first pier taut, and it would be made fast to the first pier. The weight would then be removed to the cable between the second and third piers, and the process would be repeated until every span of cable was stretched to its proper limit. The cables are carried without a break over the tops of the piers; each cable, therefore, will be 21 miles long. Above and below these cables are fastened beams of timber, over which the permanent way will be fixed. The author is informed that Mr. Ordish has pronounced that portion of the scheme relating to the piers to be practicable, and the method of floating the bases exceedingly ingenious. Another eminent engineer, the chief of one of our leading railways, but whose name the author is not at liberty to mention, has examined M. Boutet's plans for the superstructure, and states that the scheme is perfectly feasible. He, however, sees a difficulty about the piers, but, as we have it on the authority of Mr. Ordish that the piers are practicable, we may conclude the whole structure to be so. The bridge is estimated to cost £8,000,000, and to occupy three years in completing. It is stated that experiments in progress give reason to expect that this estimate will not be exceeded

The carrying out of M. Boutet's principle by the construction of bridges generally on a smaller scale than would be required for the Channel appears to be now imminent. The author understands that two small bridges have already been constructed, one for the college at Verviers and one at Senlis. A company has been formed in Paris, and the Emperor has directed a bridge to be constructed across the Seine, the first cable for which is already made. A span of half a mile at St. Malo is to be bridged upon the same principle. It would be premature to discuss the scientific details of M. Boutet's project, as they are not yet made public, and, indeed, cannot be determined until the result of some experiments in Paris, and which are now pending, are made known. The arrangements for these experiments are now nearly completed, and it is proposed that they shall be attended by the principal engineers in France and England, to whom invitations are to be sent. We may, therefore, conclude that its merits and demerits will then be investigated, and the practicability of the scheme thoroughly ventilated.

A preliminary meeting of the Channel Bridge Company was recently held in Paris, when several models of bridges upon M. Boutet's system were exhibited. One model in particular illustrated the principle of the proposed Channel Bridge. It consists of one span, and is constructed upon a scale of 1-50th of the proposed international bridge, and is formed of 21 small cables, 13 millimetres in diameter, bound together at intervals by ties at right angles, which have the effect of keeping the larger cables separate, and at the same time preserving them in their relative positions. The whole forms an open truss, which is bolted between planks of wood, thus securing perfect rigidity, which is further increased by the balustrades. It is reported that the weight of 40 persons stamping together on this model failed to produce any sensible deflection. It is estimated that it would require a weight of over 50,000 kilogrammes to break it. This model rests on abutments which have been roughly hewn in logs of somewhat decayed timber; this is a convincing proof that the abutments are not subjected to any strain.

Colburn.

Mr. Zerah Colburn has recently proposed a novel method of facilitating the laying of a tube across the bed of the Channel. He has worked out all the details, but inasmuch as the idea forms the subject of a pending patent, only a general outline of the proposition can be given. He proposes to construct a dry dock on the coast at the point where the tube is to be carried across. This dock is to be of any reasonable length, from a thousand feet to a mile, and only a few feet wider than the outer diameter of the tube. The sections of the tube are to be united together in this dock, the seaward end being fitted with a water-tight bulkhead and projecting through a water-tight opening in the dock gates. When a length of (say) a thousand feet of tubing was ready, the rear end would be fitted with a bulkhead, the water admitted into the dock, and the tube slowly towed or floated out until the last section reached the dock gates. The gates would then be closed, the water pumped out, and the work proceeded with as before. The specific gravity of the tube is to be such as that it shall just sink to the bottom, and each time it is drawn out it is to be slightly raised off the bottom by a system of buoyage, which is also to assist the flotation of the tube as it progresses in its gradual passage across the Channel. On reaching the opposite shore the tube, after being made secure, is to be lined with brick in cement, and rails laid, and in other respects the work is to be completed.

Parsons.

A pontoon vessel, of shallow draft, for the Channel passage has recently been proposed by Mr. J. H. Parsons. He connects four pontoons together by cross girders, leaving a waterway between the pontoons for the paddles, of which there are to be six—three forward and three aft. The boilers, coal bunkers, &c., are to be placed in the centre of the vessel, and the engines at each end. In the deck arrangements, the idea is to have a sleeping and a general saloon, separate from each other. A clear passage is to be left from stem to stern for working the vessel and for a promenade for passengers. This vessel, it is contended, would be rendered independent of the tide in crossing the bar at Boulogne, and would make the service direct instead of tidal as at present. The author believes that Mr. W. Bridges Adams has also proposed a somewhat similar vessel to that of Mr. Parsons.

Waring.

The present paper would be incomplete—as far as the author's knowledge extends—were he to omit to mention a proposition by Messrs. Waring to effect the Channel passage. But what that proposition is the author cannot say, as, on inquiry at Messrs. Warings' office, the representative of that firm could only say that they "had a concession." What that concession was for, whether for a tunnel, a tube, a ferry, an embankment, a bridge, or an overhead railway, the author cannot say, inasmuch as, to the author's inquiries on this point, the gentleman alluded to was specially reticent and painfully mysterious. The only subsequent light thrown upon the subject is a paragraph in a Dover paper to the following effect:—We hear from good authority that a "committee for the defence of the Channel ports" has been formed at Calais, Boulogne, and Havre, to oppose the project attributed to Messrs. Waring, the English contractors, of constructing a more convenient port near Cape Grisnez, which is certainly a very illiberal piece of obstructiveness. That the scheme is one of larger vessels and increased port accommodation appears from a statement of the Paris correspondent of the "Morning Post" of the 12th inst., and who writes thus:—We are again talking about a bridge over the Channel; the subject is sure to crop up periodically. If it is not a bridge it is a tunnel, and whether one or the other, or the proposed comfortable large boats of the Messrs. Waring, every traveller, even the non-seasick, will wish the project success.

As an embankment has been proposed as a means of facilitating the means of communication between London and the continent, it may here be briefly referred to. An embankment, however, appears to be about the worst possible solution to the problem, firstly, because of the difficulty of carrying it out, and, secondly, because of the tremendous loss of property that it would cause. In other words, it would be very difficult to find the pecuniary means, and the project would encounter the most formidable opposition from the neighbouring populations of the French and English coasts. This would arise from the damage an embankment would cause to the fishing populations of Ramsgate, Deal, Dover, Calais, Boulogne, &c. Besides, the proposer of this scheme would be puzzled to find the necessary amount of soil, making a liberal allowance for the slopes, which might be washed away a dozen times before they could settle down and acquire cohesion and stability.

Mr. W. H. Barlow has proposed a submerged bridge, but the particulars of this scheme have not come under the author's notice.

Mr. Charles Boyd proposes a marine viaduct from Dover to Cape Grisnez, constructed with iron girders on 190 towers, 500ft. apart, and 500ft. above the sea, and he estimates the cost of such a bridge at £30,000,000.

Mr. Hawkins Simpson has addressed the Board of Trade on the subject of working a submarine tunnel on a pneumatic system, which he has termed his "Eolian system," for which he claims cheapness, expedition, superior ventilation, and greater utility.

Mr. Alexander Vacherot has a scheme, on which he has been engaged several years, and which he laid before the Emperor of the French in 1856, for laying on the bed of the sea a tunnel made or formed of concrete, so as to form, when completed, a monolith. He would construct it on the shore, and draw it down to its place in sections. And he considers that greater economy and security might thus be obtained than by the other methods that have been proposed.

Estimates.

It is of course taken for granted that the adoption of either tunnel, tube, or bridge, would prove a success commercially. But as this is an important point, and one upon the proof of which any project must be dependent, it may be as well to state a few facts in support of the argument that such an undertaking will pay. It, however, needs not that very much be said upon this point, for as soon as England is directly united with the European continent, practical advantages of incalculable value will result. The resources of each country, and mutual exchange of produce, will be developed to a degree of which it is impossible to form anything like a correct idea. Mr. Chalmers went very carefully into the subject of the probable revenue to be derived from the establishment of a Channel railway. Writing in 1867, and referring to his estimate, he says:—"I published these figures in a brief prospectus of this project five years ago; and I see no reason to alter them now, unless to increase them. After I adopted them I became acquainted with the work of M. de Gamond, and on comparing figures, found a wonderful coincidence in the items of freight and passengers,

his being .	£1,041,666	13	4
and mine .	£1,049,375	0	0

He seems to have overlooked the mails* as a source of revenue, his figures were compiled in 1856, and based on the actual business then done between England and the Continent; and as he could not have foreseen the impetus that has since been given to traffic between England and France by the recent Treaty of Commerce, and by the change in the passport system, his figures are more sanguine than mine, compiled in 1861, after these important changes had actually taken place."

Mr. Chalmers estimates the probable revenue as follows:—

2,500 tons freight daily or 912,500 per annum at 12s. 6d. . . .	£570,312	10	0
1,500 passengers daily each way, or 1,095,000 per annum at 8s. 9d.	£479,062	10	0
Mails, express freight, coin and bullion, extra baggage, &c., (say)	£250,645	0	0
Total annual revenue	£1,300,000	0	0

These figures, he observes, may appear too high to those who have overlooked the affinity between improved means of transit and the increase of traffic resulting therefrom. In the infancy of railway enterprise, the anticipated traffic on a given line was based upon the business done by the stage-coaches and waggons of the day. It needs not that we compare the anticipated with the actual railway traffic, but we should bear in mind that our experience in that case did not prevent our falling into a similar error in the case of ocean steamers, though fleet after fleet of these vessels have taken their places on the ocean, each creating for itself a trade

* Mr. Chalmers and M. de Gamond have both omitted the revenue which would now be derivable from the electric telegraph companies.

where none such existed before. Between 1820 and 1830, in the good old times of sailing packets, the number of travellers between England and the continent did not exceed 80,000 per annum. The establishing of a regular steamboat service raised the number in 12 years to 350,000; and since the introduction of railways, it has risen to upwards of a million. This great increase is not to be attributed to the increase of the populations, but mainly to these improvements; and the effects that would result from the completion of any work connecting England with the continent would be even greater than were produced by those two important revolutions in locomotion, which respectively raised the figures from 80,000 to 350,000, and from the latter to upwards of a million.

In confirmation of these views we find Captain Tyler stating, in a recent report upon the improvement of the means of communication between England and France, that, omitting from consideration the ports of Hamburg, Rotterdam, Antwerp, and Ostend, the passenger traffic between England and France for the year 1868 amounted to 309,479 altogether; 141,633 passengers having travelled by Calais, 109,006 by Boulogne, 41,871 by Dieppe, and 17,469 by Havre. A large proportion of these, namely, 46,411, crossed the Channel in the month of August, as against 12,946 in January, and 13,514 in February. In the year 1867, of the Paris Exhibition, the numbers were 454,350 altogether; 199,837 having travelled by Calais, 146,226 by Boulogne, 86,914 by Dieppe, and 21,373 by Havre. Of these, 84,684 crossed in August, against 13,163 in January, and 13,721 in February. Captain Tyler observes that in addition to the ordinary annual increase, which is considerable, there would naturally be a very large augmentation in these numbers if better arrangements were made for crossing the Channel.

Conclusion.

We have now definitively before us three propositions for effecting the desired communication by means of an excavated tunnel, three for laying a tube on the bed of a channel, three for improved steam vessels, and one for a bridge, besides several other propositions of minor importance and questionable practicability. Of all these projects undoubtedly those which have of late made the greatest progress are the bridge scheme of M. Boutet and the tunnel scheme of Messrs. Hawkshaw, Brunlees, and Low. The documents relating to this latter scheme are now before the Board of Trade. The results of the deliberations of a French Commission appointed by the Emperor to inquire into the scheme are, on the whole, favourable as regards the geological and engineering features of the project. In this scheme it is proposed to commence by driving preliminary driftways through the grey chalk, at a great depth below the bed of the Channel, between a point near Dover and another point near Calais. It is conceived that this material would be easily cut through, and would not be likely to present insuperable difficulties from the influx of water. Mr. Remington, as we have already seen, selects the line from Dungeness to Cape Grisnez, in order to avoid the chalk and the fissures which he fears to encounter in it, and to work in the Wealden formation, which would, he believes, afford a greater chance of success.

Turning to M. Boutet's bridge scheme we find that an association has been formed for making experiments, two small bridges have been built in France, and arrangements are made, near St. Malo, for a third, whilst a fourth is to be constructed over the Seine. The great features of the bridge are that it will be less costly than a tunnel; will occupy less time in construction; will give no trouble in ventilation; and will avoid the danger of sudden inundations. As to its merits in an engineering point of view, we may hope shortly to be satisfied by practical demonstration.

Looking broadly at the schemes which present the most reasonable features, and irrespective of their engineering merits in detail, it appears to the author that, of the tunnel schemes, that of Mr. Remington for driving through the Wealden formation would be attended with less danger than that of Mr. Hawkshaw, which it is proposed to carry through the chalk. Of the methods of connecting the two shores by tubes along the bed of the Channel, that of Mr. Bateman certainly appears the most practicable. If these tubes could be constructed in a dry dock and drawn gradually over upon Mr. Colburn's method, it would be a very summary method of settling the question, as Mr. Colburn assures the author he could effect the connection in three months, although, he admits, at a great cost. But, both in subterraneous and subaqueous works, there is an admitted possible risk. In the former, there is the contingency of flooding from the nature of the soil, whilst, in the latter, some of the operations would be dependent on comparatively delicate arrangements. The bridge scheme has also its perils of storms and tempests, but there appears to be a possibility of guarding against the consequences of these more readily than against the insidious advances of a great head of water. The bridge scheme, too, as has already been observed, has had its substructure approved by one independent engineer, and its superstructure by another. As far, then, as we have at present advanced, the bridge scheme appears to present the most reasonable chance of success. But either a tunnel, a tube, or a bridge would be the work of perhaps eight or ten years, for the author does not think the various projectors have allowed sufficient time for the contingencies that would arise in the course of carrying out works of such unparalleled magnitude. We must, therefore, turn to some plan by which the existing requirements of the travelling public can be promptly and inexpensively met.

Captain Tyler, R.E., has examined the English and French coasts and investigated the various projects, and has reported to the Board of Trade thereon. Referring to Mr. Fowler's plan for improved steam vessels and harbour accommodation, Captain Tyler observes that the project would require some modifications in detail, and that it is a question whether it would be worth while to ferry the railway carriages as well as the passengers across the Channel. But the main features, of an improved harbour at Dover and a new harbour south of Cape Grisnez, are sound, if means can be found for meeting so great an expense.

With regard to Mr. Grantham's proposition to utilise the existing harbours by vessels of light draft, Captain Tyler states that it is asserted by some of the officers engaged in the performance of these services that vessels of the class now employed are, upon the whole, the safest that could be devised for the particular duties required of them. It is argued that the sea-passage, in which greater length and size might lead to increased comfort, is comparatively short, while the entrance of the French harbours, by day and night, in certain states of the weather, which is already the more difficult and dangerous part of the service, would be attended with still greater disadvantages. The existing vessels are fitted to encounter any weather with which they can meet in the Channel, and are handy for entering the harbours, while longer vessels would be exposed to increased risk at the moment of entering the harbours. The bow of a long vessel getting under the shelter of one pier, and a heavy sea striking her on the quarter, she might be driven against the other pier. There is, no doubt, much truth in this argument. Such a risk must increase in proportion to the length of a vessel, to the narrowness of the entrance to a harbour, to the exposed position of its entrance as regards winds and currents, and to any necessity which may exist for reducing the speed before entering it. Having regard to the existing state of the French harbours, the employment of longer vessels would, for this reason, be attended in bad weather with greater danger. But the argument would no longer apply if the service were performed from a convenient and well constructed pier on the one to a similar pier on the other side of the Channel. The longer and larger vessels having increased proportional power, with disconnected engines, so as to be able to use either paddle at pleasure, could be under no disadvantage in approaching the lee side of a pier. The above argument, therefore, tells in favour of the construction of an extended pier at Boulogne, as proposed some time since by Mr. Brunlees, to be used on the French, in combination with the pier at Dover on the English coast, for an improved Channel service.

The matter, then, in general terms stands thus:—The steam packet service between England and France is greatly in need of improvement. This service is important in its character, and the existing steamers, restricted as to their dimensions for want of better pier and harbour accommodation, are not proportionate to the importance of the service. Larger vessels, with less movement in rough weather, more shelter, and better accommodation generally, would do much to mitigate the discomforts of the sea passage; and even contemplating the successful issue of a tunnel or bridge project, these improvements are much required, and should be effected in the meantime. But larger vessels cannot be employed for a fixed service until better provision is made for embarking and disembarking passengers, especially on the French coast. The pier at Dover is not only ready, but has frequently been used for military transport-vessels of the largest size, though certain improvements are required in the jetties for greater convenience in embarkation and disembarkation. The difficulties in the way of fitting the harbour of Calais for the reception at all times of larger vessels are great, but by a judicious extension of the west pier at Boulogne, similar accommodation might be provided on the French side. Captain Tyler estimates that at a cost of about £100,000 at Dover, and £500,000 at Boulogne, the desired object might, apparently, be attained in the most economical and most expeditious manner. By the adoption of steamers capable of moving with equal facility in either direction, the difficulties incidental to turning round in small harbours may be avoided; and the existing harbours at Dover and Boulogne might, with certain modifications, be made available, to some extent, for improved vessels.

Captain Tyler suggests that the question might thus be temporarily solved if the two governments were not prepared to carry out a larger scheme. If they are prepared to face a greater expense, there is the more extensive project of Mr. Fowler, for constructing, at a cost of two millions of money, special harbours for special steamers. There can be no doubt that this project presents, whether the railway carriages be ferried over or not, a more comprehensive mode of dealing with the subject. The relative distances may be stated to be:—Between Dover and Audresselles, 24, Dover and Calais, 26, and Dover and Boulogne, 30 English miles; while the passage to Boulogne, though longer, is admitted to be better than that to Calais. Either by the construction of new harbours at Dover and Audresselles, at a cost (as estimated by Mr. Fowler) of £2,000,000, inclusive of steamers, or by the improvements above suggested at Dover and Boulogne, at a cost of £600,000, exclusive of new and improved steamers, the immediate object should be to provide an improved fixed service, irrespective of wind and tide, between London and Paris in eight hours. It would appear to be desirable now to refer the whole matter, through the Foreign Office, for the consideration of the French government, with a view, perhaps, to the appointment of an international commission, in which that government would, no doubt, readily acquiesce, and without which the important interests involved could not be authoritatively dealt with, nor the general question satisfactorily decided.

Whatever be the plan ultimately decided upon for connecting England and France in a direct manner, such a plan must have the best wishes of those here present this evening as well as those of the whole civilised world. It should not be so much the honour of adopting this, that, or the other scheme that should influence us as the reflection that the accomplishment of the object will be attended by advantages to the nations of the earth. In former times, when Europe was regarded mainly as a theatre of war, it was, perhaps, no disadvantage for this country to be separated from it. But, since the introduction of steam has so completely changed the character of marine locomotion, any advantage formerly arising in this respect from our insular position has been materially diminished, and, in the present day, it is continental commerce from which we are separated and not continental wars. Such a direct bond of union, then, as is proposed would establish on the firmest basis the spirit of amity now subsisting between England and France.

We understand that last week several of the principal coal and iron masters of the South Wales district received a communication from Mr. A. Basset, C.E., of Cardiff, asking their support towards the construction of a line of railway between Lydney and Stonehouse. The scheme, which is 11¼ miles in length, includes the construction of a tunnel 1,320 yards in length, under the River Severn, at a point about a mile and a quarter above Lydney; the line will join the Midland Railway near the Berkley-road Station, and the Great Western Railway near Stonehouse. By this route the distance between the South Wales district and London will be shortened to the extent of 17¾ miles, thereby reducing the cost of coals alone to London by upwards of 1s. per ton. The time saved by the passenger express trains will be at least 30 minutes, and ordinary trains 48 minutes. The cost of the works is estimated at £300,000, which includes a double line laid with broad and narrow gauge.

IMPROVED PUMPING MACHINERY.

BY MR. J. VIVIAN.

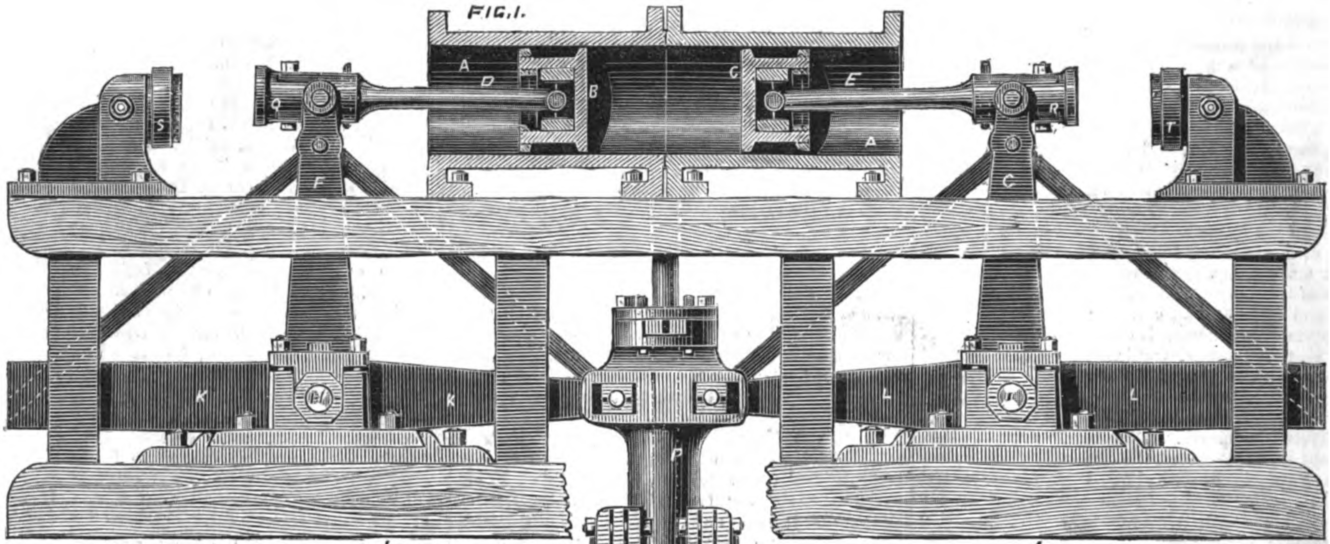


FIG. 2.

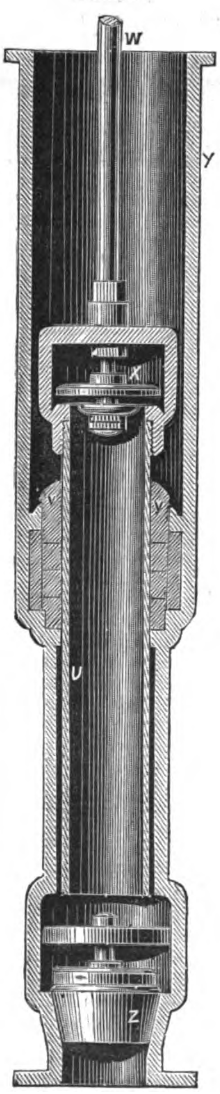

FIG. 3.

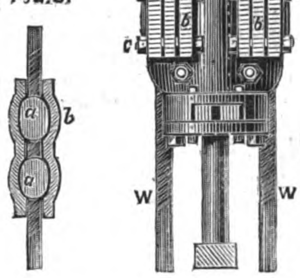

FIG. 4.

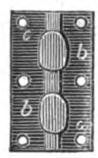


IMPROVED PUMPING MACHINERY.

SOME special improvements in engines and pumps have just been patented by Mr. James Vivian, of Falmouth, through the agency of Messrs. Robertson, Brooman, and Co., patent agents, of 166, Fleet-street, London. The invention consists, first, in fitting two pistons in one cylinder; these are driven outwards by the action of steam admitted to the cylinder at about the middle of its length. The rods of each piston are connected to vertical arms of rocking frames free to oscillate on arms or axles. The inner ends of the rocking frames are jointed to a crosshead or coupling plate capable of having an up-and-down movement imparted to it on a guide rod. This crosshead supports the ropes or rods by which the plungers are worked. When the steam has driven the pistons the full length of their stroke, the exhaust leading to the condenser is opened, whereby a vacuum is formed. The outer air then acts upon the pistons and drives them inwards to their first positions to be again acted upon by the steam as before mentioned.

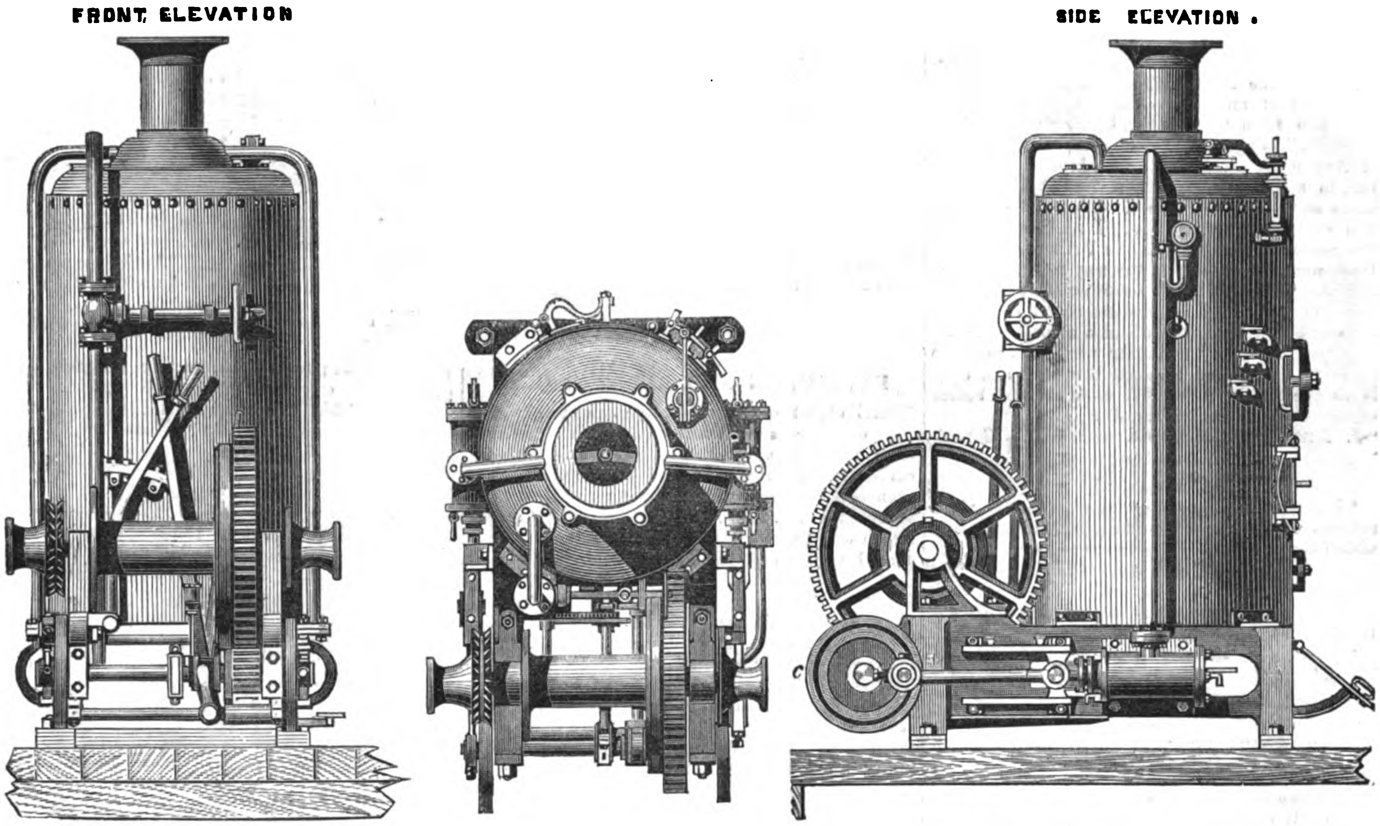
Fig. 1 of the accompanying engraving shows a sectional elevation of a cylinder A, in which two pistons B C are fitted according to this invention. Both pistons are shown at about the middle of their stroke, that is, about mid-distance between the central part of the cylinder and the outer ends. The entrance for the steam into the, cylinder may be at any part of the central portion, either at the top, at the sides, or at the bottom, as found most convenient; and its pressure causes both pistons to travel towards the ends of the cylinder at the same time, each piston forming an abutment for the steam to act against. The supply of steam may be cut off at any part of the stroke, so that the quantity admitted may be used expansively or not, as required. When the pistons have travelled a fixed distance, they uncover a port at each end leading to a condenser, so that the cylinder becomes empty. The ends of the cylinder A are open for allowing the connecting rods D E, which are jointed to them, to follow the course determined by the motion of the vertical arms F G pinned to their outer ends. These vertical arms are centred upon journals H I within bearings upon a foundation J, and admit of a rocking motion being given to the vertical arm F G and the other parts K L of the rocking frame, of which **they form part, when the pistons are at work. The parts K L, with the tie rods M N, form a compact and strong framing for lifting the pump crosshead or coupling plate P, which is connected to the inner ends of the parts K K, while the parts L L act as a counterpoise, and, from their situation, they assist in bringing the inner ends of the parts K K upwards while the steam is acting upon the pistons. The crosshead P is provided with slots for the blocks of the journals of the parts K K to slide in during the up-and-down movements of the pump plunger. The crosshead** P is hollow and rides upon a fixed guide rod Q, which passes through it, so that it shall work in a straight up-and-down easy manner without any liability to jamb, either in the up or in the down stroke. Both ends of the crosshead are furnished with endpieces, which are screwed down upon them to retain the lubricated material in place. The lubricant with which the material is supplied serves to keep the guide rod Q well greased. The outer ends of the connecting rods D E are fitted with springs or buffers R R, so that, when the pistons have been driven the required distance, the buffer ends strike against fixed abutments S T, whereby the springs receive the blow or shock which would otherwise be given to the frame, and which of course would, in a short time, prove detrimental to the effective working of the engine and machinery.

The second part of Mr. Vivian's invention consists in fitting a tube inside the pump barrel; one end of this tube carries a valve on which it finds its seating; the valve is guided in its movements by a stud or pin on which it is free to rise and fall. The upper end of the tube is connected by a bracket or loop to the plunger rod. A portion of the barrel in which the tube works is packed to prevent passage of water from one part to the other. The lower part of the barrel has a valve fitted in it, and, as the tube is lifted, the lower valve rises from its seat (the upper valve being shut and resting on the end of the tube) by the suction of the tube, the water rises up above the lower valve and fills the space between it and the tube. On the down stroke of the tube the lower valve shuts, and the water from the space lifts the tube valve and passes up into the space in the pump head, from which it flows away in the required direction.

This second part is represented in the sectional **view fig. 2. U is the tube, which is fitted inside the barrel V and receives an up-and-down motion from the rod W. The upper end of the tube is looped as shown for the rod W to be connected to, and also to retain the upper valve X in place. The stem of the valve rides in an aperture formed in the loop so that the valve is guided into position both in the up-and-down stroke of the tube U. The barrel in which the tube works is packed, and, to facilitate the packing being got at, a cover or plate Y is fitted on one face of the barrel; this plate is secured by screw bolts as shown. Below**

PORTABLE OR FIXED STEAM WINCH.

BY MESSRS. GRAVELEY.



the tube U, and in a recess formed in the barrel is a valve Z, which has an up-and-down movement imparted alternately to it by the suction and the back pressure of the water. This mode of constructing pumps is applicable to all kinds of pumping apparatus, and may be employed in pumps which work horizontally as well as in those which work vertically.

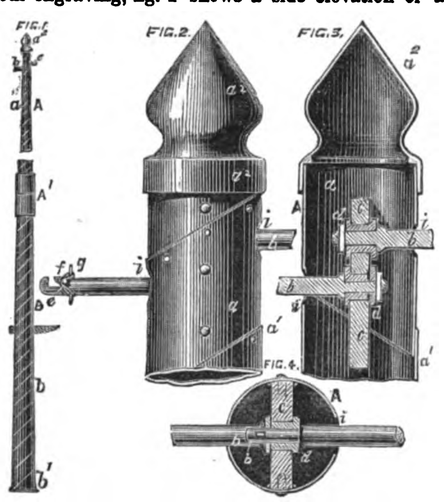
Mr. Vivian's invention consists, thirdly, in fitting balls or lumps on the ends of the wire ropes by which the plungers of the pumps are worked. These balls may be formed of metal secured to them by soldering, or they may be formed of solder. The ropes are connected to the plungers and to the crosshead or coupling plate by fixing the balls between plates formed with recesses to receive them, which plates are firmly clamped by bolts and nuts. Fig. 3 is a view of the end of a rope, with balls or lumps *a a* formed on it. These lumps are received in recesses formed for them in the inner faces of the plates *b b*, which are firmly bolted together by bolts being passed into the holes *c c c*, as seen in fig. 4. If it is desired to connect the ropes to the crosshead direct, the recesses for the lumps are formed in one or more of the faces of the same as shown in fig. 1, and plates similarly recessed are secured over them. These lumps may be made by bulging the rope out at the required part, by placing loose pieces of metal under and between the strands, or loose pieces of metal may be secured on the ropes by solder. This way of connecting ropes for mining and other purposes will be found of great service in repairing broken or overstrained ropes, or ropes in which weak places are found.

STEAM WINCH.

In the accompanying engraving we illustrate a very cheap and simple form of steam winch, introduced by Messrs. Graveley, to meet the wants of shipowners who do not require heavy and expensive apparatus. The construction of the winch is so clearly shown that no particular description is required. The motion of the valves is changed for reversing by a very simple and ingenious arrangement of inclined gear, which works to perfection. The entire arrangement is neat, compact, and calculated to meet the desired end. Distilling apparatus can be combined with the engine when required.

METAL TUBES FOR TELEGRAPH POLES.

The manufacture of metallic tubes for various purposes has been improved upon by Mr. F. N. Gisborne, of 445, West Strand, and Mr. H. Allman, of Ampthill-square. In a patent recently obtained by these gentlemen we find that they employ strips of metal coiled spirally around so as to form a spiral lap joint. These joints or laps are either riveted, welded, soldered, brazed, or galvanized together. By forming tubes thus, it is claimed that a maximum amount of strength with a minimum weight of material is obtained. In constructing posts or poles for telegraphic purposes, the inventors form each post of two parts in the following manner:—The base is made of strips of galvanized iron, and a plate of larger diameter is affixed thereto, so that when it is sunk into the ground it may be filled internally with earth previously to the upper portion of the tube being fitted. The upper tube is provided with an inner piece of ebonite, to which the metal arms are attached. These metal arms pass through openings in the tube. At the outer extremities of these arms the telegraph wires are carried. In our engraving, fig. 1 shows a side elevation of a



telegraph post. It is composed of two parts, A and B. The upper part A is at its lower end fitted with a socket A [1], which fits on to the upper end of the part B. The parts A and B are tubes composed of strips of metal *a* and *b* wound spirally on a mandrel, and the strips *a* and *b* are, in this case, as they are wound, lapped slightly the one over the other, and these laps are connected by riveting. The lower end of the tube B is provided with a flange or plate *b* [1] extending outwards beyond the width of the tube; it serves to give additional strength as well as to steady the lower part, which is embedded in the ground.

At the upper portion of the part A of the telegraph post arms are mounted; the outer ends of these arms carry the telegraph wires. The arms are insulated from metal posts as seen by figs. 2, 3, and 4, which show respectively a side view, a sectional elevation, and a horizontal section of the upper part of the telegraph post A upon an enlarged scale. *a* is the strip of metal of which the post is formed by lapping, as shown at *a* [1], with a top or cover *a* [2]. Arms *b b* are supported by an insulating block *c c* of suitable material connected to the tube A, and fitting into openings formed in this block are tubes or insulating pieces of vulcanite *d d*. Into these the supporting arms *b b* are placed, their ends being secured by keys. The telegraph wires *e e* are carried by the arms *b b* at their outer ends, where they are secured by wires *f f* to a cross pin *g*. The holes *i i* in the tube A are sufficiently large to allow of a clear space around the arms *b b* so as to ensure perfect insulation to the telegraph wires from the metal posts.

THE EDMUNDS CASE.

The Court of Arbitration in what is popularly known as "the Edmunds Scandal Case" commenced its sittings yesterday week at Westminster. The case against Mr. Edmunds was opened by the Attorney General in a speech of great detail, in which the defendant was charged with numerous irregularities and defalcations. Mr. Edmunds alleges that he accepted the office upon the understanding that out of the amount of his salary he was to pay £300 a-year to the Brougham family, which was to be applied to the maintenance of the widow and children of Mr. James Brougham, and that the arrangement was conducted by Mr. William Brougham. At a subsequent sitting, the Court decided that the question whether out of a salary of £400 Mr. Edmunds was to allow the Brougham family £300, was wholly irrelevant to the present inquiry. The inquiry continues to drag its slow length along, the Court having decided to sit *de die in diem* until the investigation is concluded.

DR. LIVINGSTONE.

THE following is the text of the letter (dated August 31, 1869), received by the Bombay government from Dr. Kirk, political agent at Zanzibar, relating to the supposed arrival of Dr. Livingstone at Ujiji:—

"Sir,—I have the honour to report for the information of the Right Honourable the Governor in Council that an Arab caravan arrived here two days ago from the interior, bearing a letter from Synd Majid's agent at Anyayembe, in the country of Anyamwezi, addressed to his brother at Zanzibar, in a P.S. to which the arrival of Dr. Livingstone at Ujiji is mentioned. I forward a copy of this extract in translation. I am informed that the native messenger who saw Dr. Livingstone at Ujiji was one month on the way to Anyayembe, and that, therefore, this information is at least a few months old. I understand that a caravan is expected on the coast in about a month, when we may possibly receive further news of the great explorer. The road between the coast and Ujiji is at present open and safe, even to small bodies of men.—I have the honour, &c.,

"J. KIRK, Political Agent and H.M.'s Consul, Zanzibar."

(Translation.)

"Postscript.—Be good enough when the slave returns to send a box of brandy similar to that which came for the white man, one of which was broken on the way, so that none remained. And he (the white man) has reached Ujiji, and may pass this way, and on his coming we will give it to him. Do not neglect this.

"Dated 4th Rabin-el-Awul 1286 (June 12, 1869)."

SUBSTITUTE FOR FIRE-BRICK.

MR. JOHN CLIFF, of Runcorn, has patented some improvements in the method of using and applying certain materials in an unmanufactured state, in order to form a substitute for fire-bricks or fire-goods hitherto employed in the construction of furnaces in which fire-bricks, tiles, and other various forms of fire-goods are usually applied. Instead of using fire-bricks, lumps, stones, tiles, or other forms of materials or compounds in construction burnt or unburnt, he uses powdered ganister stone, quartz, sand, mica, sandstone, or other siliceous material, plumbago, lime, baryta, steatite, and magnesia, alone or separately, or in varied proportions with fire-clays, or with each other, or with siliceous or other solutions, mixed or not with hair, fibre, sawdust, shavings, or pulverised coke, or with other analogous materials. In applying the materials in a plastic state wire may be used as a supporter, or a skeleton or light framework may be used to support the materials while in course of application to the furnace until the material is dry enough. Thus the furnace is built entirely of such materials in their raw or plastic state in connection with brick or other walls, the object being the substitution for fire-goods, and their consequent cost of manufacture, fuel, carriage, and skilled labour, of unmanufactured materials that can be used and applied by cheap labour more speedily and economically. Thus time and expense will be saved in construction, andit will not be necessary to keep large stocks of var ed shapes of bricks, the loss of material and la our in making joints will be saved, whilst, inc se of actual wear, additions can be supplied inter lly or externally to the structure so that it ma be easily and speedily repaired.

OUR SHIPS OF WAR.

TWO Parliamentary returns, which were moved for in the House of Commons by Mr. Laird, have recently been issued relative to Royal Navy vessels of all classes now building, or that have been ordered to be built during the current year. Of iron-plated ships and batteries 14 are now being built, all of which, with one exception, were designed in the Controller's Department of the Admiralty, and all, with two exceptions, on Mr. Reed's plan. The "Captain" and the "Glatton" are designed on Captain Cole's turret plan, the former being specially designed by Captain Coles and Mr. Laird. The engines of these vessels will be furnished respectively by Messrs. Penn, Laird, Maudslay, Ravenhill, and Napier, and all, with the exception of those in the "Repulse," will be constructed on the improved expansive plan, with surface condensers. Seven are building or will be built in the Royal dockyards, two in that of Messrs. Laird Brothers, three at the works of Messrs. Napier and Sons, Glasgow, and two at those of Palmer's Company. No floating batteries are building or ordered to be built. The return of vessels not armour-plated shows that a total of 12 vessels of this class are now building or ordered to be built—two by the Thames Company, Blackwall, two at Woolwich, two at Portsmouth, one at Devonport, two at Sheerness, two at Pembroke, and one at Chatham. One will be built of iron, nine of wood, and two of iron cased with wood, and three will be furnished with double screws. The vessels vary in tonnage from 212 to 2,322 tons, the estimated first cost of their hulls from £5,653 to £75,453, and the labour and materials from £3,090 to £68,608.

EXTRACTING AND REFINING OILS.

THE object of the invention we are about to describe is to obtain oils and other products from mineral and other materials containing carbon and hydrogen in a more satisfactory and economical manner than heretofore. It has been patented by Mr. Townsend, of Glasgow. According to one method, steam generated in a boiler is passed through piping immersed in a bath of melted metal or alloy, or of a salt in solution or fused, which superheats it and keeps it at a uniform temperature, and it is then admitted into a retort or still containing the materials from which the oils or other products are to be extracted. The superheated steam enters the upper end of the retort, and is maintained therein at a pressure of at least ½lb. per square inch above that of the atmosphere. Pressures ranging from 10lb. to 20lb. per square inch, and the steam superheated to from 600deg. to 1,000deg. Fah., are preferred by the inventor. The retort is in the form of a vertical cylinder of a large size, 12ft. high by 12ft. in diameter, and built of iron plates lined with firebrick. It is made with a perforated bottom, down through which the steam and what it extracts pass to an inclined bottom leading to an exit pipe at the side, and this pipe first descends a little and then ascends, whilst at the top of it a loaded valve is applied, which prevents the passage of liquids or gases except at a predetermined pressure, to which the valve is loaded and which is that intended to be maintained in the retort. A safety valve is provided on the retort itself to act in the event of the exit pipe being choked; and the retort is also fitted with man-hole doors for introducing the materials and for removing the coke or residue.

The exit pipe from the retort communicates with condensing coils of piping in cisterns maintained at different temperatures, and branch pipes are provided to drain off whatever condenses in the condensing coils. The products of distillation are passed first through the hottest condensing bath or cistern, and then whatever remains in the form of vapour passes on to the next colder one, and so on throughout the series. If a hotter condensing bath is wanted than one with boiling water in it, it is obtained by making the bath of melted metal or alloy, or of a salt in solution or fused, and the temperature of the colder baths is regulated by adjusting the supply of water, the coldest water passing first into the coldest bath and then through the hotter ones in succession. The steam may be superheated by means of metal filings, or of metal, sand, or other refractory materials in a granular form, or by any convenient apparatus already in use for such a purpose, but the temperature must be carefully regulated, and the arrangements here described are preferred on account of their facilitating the maintenance of a regular heat.

In refining oils or in extracting oils or other products from tar or from substances which are more or less liquid when heated, a retort or still of a somewhat different construction is employed, being made with horizontal platforms with ledges, and extending alternately from opposite sides to within short distances of the other sides. The tar is put on the top platform and overflows in succession down upon each lower one, whilst the heated steam or gas flows over its surface and passes off with what it extracts by the exit pipe. Man-hole doors are provided in the sides of the retort at the ends of the several platforms for removing solid residues from them.

SALE OF GOVERNMENT STEAMERS.

LAST week saw another batch of her Majesty's steamers put up for sale at public auction at Lloyd's Captains' Rooms, by order of the Lords Commissioners of the Admiralty. The sale attracted a large attendance, and among those present were the leading shipowners of London, Liverpool, Glasgow, and most other seaports on the coast. Mr. Geo. Bayley, of the firm of Bayley and Ridley, was the auctioneer. The first vessel offered was her Majesty's gun vessel "Ranger," now lying at the Royal Dockyard, Sheerness. She is described as 427 tons builder's measurement, built of wood, at her Majesty's Dockyard, Deptford, in 1859, having screw and paddle engines of 80-horse power; her average speed was reckoned at about nine knots per hour. The biddings commenced at £500, and she was knocked down for £1,725. The next vessel was her Majesty's gun steamer "Surly," also lying at Sheerness. She was stated to be 337 tons; built at Newcastle, of wood, in 1856; flush deck, copper fastened, and fitted with engines of 50-horse power. She fetched £1,025. The next offered was her Majesty's iron screw store ship "Dromedary," lying at Sheerness. She was represented by the auctioneer as a very strongly-built vessel, well adapted for mercantile purposes. She is 654 tons, built by Messrs. Samuda Brothers, at Millwall, in 1862, barque-rigged; engines of 100-horse power, and has wire rigging. Her stores and fittings were included in the sale. She was knocked down for £5,100. The last sale was that of her Majesty's screw corvette "Malacca," lying at the Royal Dockyard, Portsmouth. She is 1,034 tons, principally built of teak, in her Majesty's Dockyard, at Bombay, in 1853; ship-rigged, with engines of 200-horse power, her average speed about 8 knots. The biddings offered ranged from £5,000 to £7,800. Mr. Bayley then stated that the reserve price on the ship was £12,000, and he therefore bought the vessel in for the Admiralty. The vessels sold were considered to have realised more than their actual value.

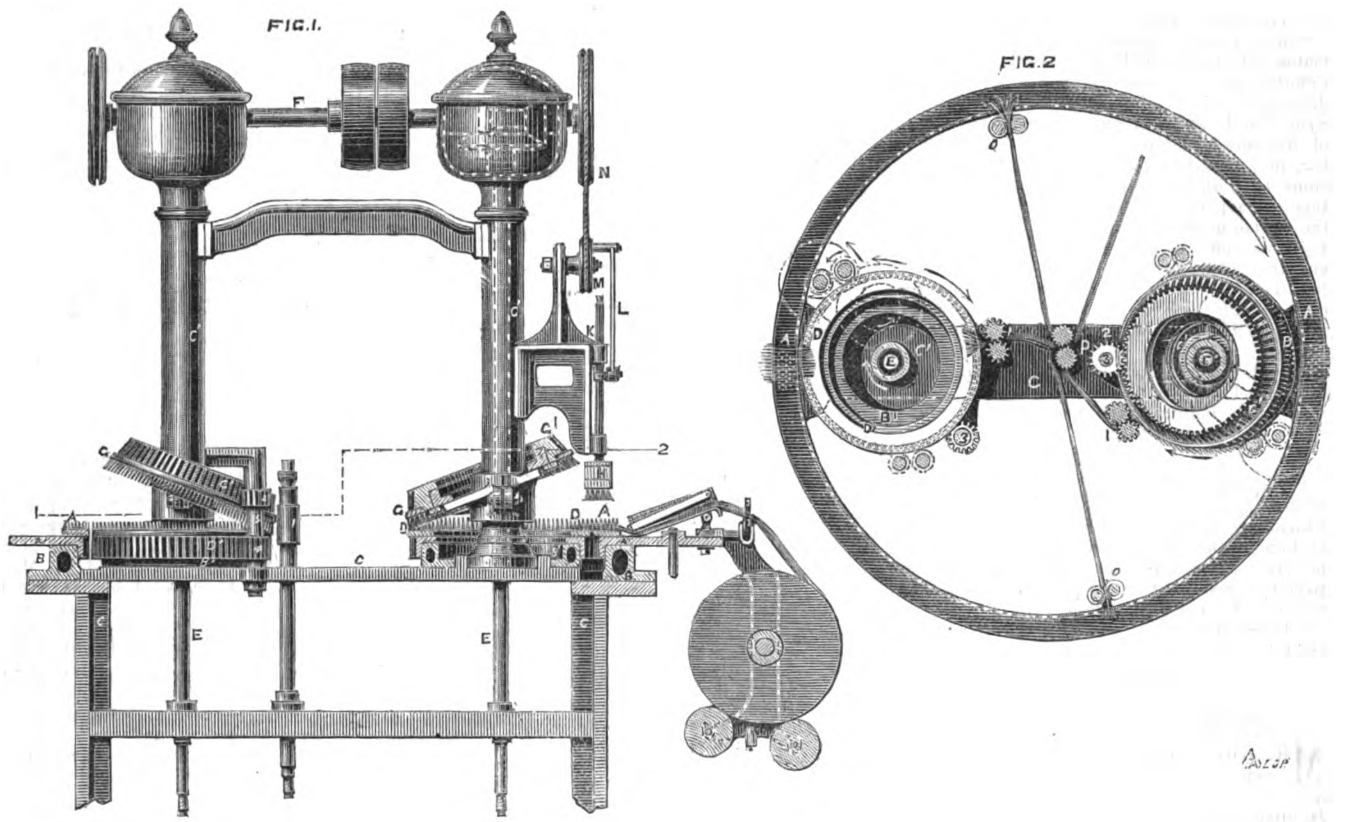
MACHINERY FOR COMBING WOOL.

THE invention illustrated herewith relates to improvements on the machine known as Noble's combing machine, in which two horizontal circular combs are employed set one within the other and in tangential contact at the point where the fibre to be combed is supplied to the comb teeth. This machine has from time to time undergone several changes, but by the present mode of combing in Noble's machine there are certain noil neps, burrs, and other impurities which get between the large and small combs, and are not cleared in consequence of the separation by revolution of the two combs. The object of some improvements recently patented by Mr. H. W. Whitehead, of the firm of Taylor, Wordsworth, and Co., of Holbeck, Leeds, is to effect the clearing of the fibre from the noil and other impurities. This is done by causing the teeth of an inverted circular comb to work between the inner and smaller circular comb and its drawing-off rollers. By this means the noil neps or other impurities are prevented from passing off with the combed top or sliver band, a cleaner fibre being thus obtained.

In our engraving, fig. 1 shows in sectional elevation so much of the improved combing machine as will serve to explain the invention, and fig. 2 is a sectional plan view of the same, the section being taken in the irregular line 1 2 of fig. 1. A A is the large circular comb affixed to an annular plate A^1 A^1, which slides on an annular bed B carried by the framing C of the machine. Within this comb A are mounted two small circular combs D D, which virtually touch the outer and surrounding comb tangentially at opposite points of its inner periphery. These combs D are affixed to annular slides D^1 which rotate on annular beds B^1 carried by the framing. The slide A^1 is cast with rack teeth on its inner periphery, and the slides D^1 have spur teeth on their outer periphery for the purpose of receiving rotary motion from gearing, as we shall presently explain. Through the centres of the circular combs D and through hollow pillars C^1 concentric therewith pass vertical shafts E, which turn in bearings in the framing C. These shafts are each fitted at top with a bevel wheel into which gear bevel pinions carried by the horizontal driving shaft F. The rotation therefore of this shaft by a belt passing over its fast driving pulley will give rotary motion to the shafts E E. A spur pinion

MACHINERY FOR COMBING WOOL.

BY MR. H. W. WHITEHEAD.



on these shafts below the level of the combs serves by means of a train of gearing 1 1 (see fig. 2) to drive the comb A and the combs D D in the direction of the arrows and at a uniform surface speed.

Mounted on circular tilted beds affixed to the pillars C^1 are the inverted circular combs G G. These combs overlie the combs D and work at such an angle thereto as to allow of the free motion of the dabbing brush H, which strikes vertically into the teeth of the combs A and D to press the fibres (as they are fed to the machine) well into the combs. The combs G are made conical and of a somewhat larger diameter than the combs D, so that they may respectively overlap the teeth of the combs D at the point opposite which the drawing-off rollers I are situated, and by that means intercept the noils and other impurities in the fibre contained in the combs D. The comb plate G is secured to a conical annular slide G cast with teeth on its periphery, which teeth when they arrive near the drawing-off rollers assume a vertical position. Into these teeth gears a pinion 2 keyed to a short vertical shaft 3 supported in bearings, and which carries also a second pinion 4 in gear with the teeth on the comb slide D^1. Thus rotation is transmitted from the comb D to the comb G, and the gearing is so arranged as to ensure an uniform surface speed to the two combs.
